The growth of services in the ever-evolving global economy has brought much needed attention to service science and service systems engineering (SSE). Research focuses on developing formal methodologies to understand enterprise-end-user (customer) interactions from both socio-economic and technological perspectives, and to enable value co-creation and productivity improvements. Service systems require trans-disciplinary collaborations between society, science, enterprises, and engineering. Service transactions are customized and personalized to meet a particular customer need. This requires a disciplined and systemic approach among stakeholders and resources to emphasize end-user satisfaction in the design and delivery of the service (Hipel et al. 2007; Tien and Berg 2003; Vargo and Akaka 2009; Maglio and Spohrer 2008; Maglio et al. 2010).

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs in turn are divided into topics. This KA contains the following topics:

- Service Systems Background
- Fundamentals of Services
- Properties of Services
- Scope of Service Systems Engineering
- Value of Service Systems Engineering
- Service Systems Engineering Stages

Introduction

New Service Development (NSD) has usually been a proprietary process closely guarded by product businesses and service businesses for their competitive advantage. Traditional systems engineering practices have been primarily applied in aerospace and defense sectors while SSE practices have been applied by information and communications technologies (ICT) service providers (Booz, Allen, and Hamilton 1982; Johnson et al. 2000; Eppinger 2001; Freeman 2004; Whitten and Bentley 2007; AT&T SRP 2008; Lin and Hsieh 2011).

These early efforts were, and in some instances remain, very important for product and service businesses. However, the growth and ubiquity of the World Wide Web, advances in computer science and ICT, and business process management through “social networking,” support the realization of closely interrelated service systems. Product business (manufacturing, agriculture, etc.) and service business distinctions are going away (Spohrer 2011).

These services, or service innovations, must take into account social aspects, governance processes, business processes, operational processes, as well as design and development processes. The customer, service provider, product provider, and intermediaries need to collaborate toward the optimization of customer experiences and customer provided value (through co-creation). The interrelations among different stakeholders and resources require that methodologies, processes, and tools be dynamically tailored and delivered for either foreseen or newly discovered services to rapidly adapt to changing enterprise and end-user environments.

Even in the case of static, predetermined, interaction rules, the major problems faced in the definition, design, and implementation of services have been in understanding the integration needs among different systems, system entities, stakeholders, and in defining the information flows required for the governance, operations, administration, management and provisioning (OAM&P) of the service. (Maier 1998; Jamshidi 2008; Pineda 2010; Luzeaux and Ruault 2013). Thus, the 21st century technology-intensive services are “information-driven, customer centric, e-oriented, and productivity-focused" as discussed by Chesbrough (2011), Chang (2010), Tien and Berg (2003), and Hipel et al. (2007). A detailed discussion of these characteristics is given in the Value of Service Systems Engineering article within this KA.

Service Systems Engineering Knowledge Area Topics

This knowledge area (KA) describes best practices in SSE during the service design process and outlines current research on methods, processes, and tools. It does not attempt to describe the initial efforts and research in service science that were proposed and introduced by International Business Machines (IBM) (Maglio and Spohrer 2008), but it does recognize their leadership in championing these concepts in undergraduate and graduate curricula.

The rest of the KA is organized in the following way:

The Service Systems Background article presents some background on the transition from a manufacturing economy toward the service economy brought by the World Wide Web through co-creation of end-user value. It describes how this transformation is impacting industries, such as healthcare, agriculture, manufacturing, transportation, supply chain, environmental, etc. The article also describes the scope of the SSE discipline's contributions to meeting the needs of the service sector companies in strategic differentiation and operational excellence (Chang 2010) by pointing out some differences between product-oriented systems engineering and SSE.

The Fundamentals of Services and Properties of Services articles take the reader through a general discussion of services and current attempts to classify different types of services, in particular, attention is paid to the properties of service systems for the service sector, such us transportation, environmental and energy services, consulting services, healthcare, etc.

The Scope of Service Systems Engineering and Value of Service Systems Engineering articles cover the value of SSE, defining (or using when available) service architecture frameworks, and the stages of the service development process from concept to life cycle management.

The Service Systems Engineering Stages article summarizes the major SSE process activities that need to be carried out during the service design process and the needed output (work products) in each of the service design process stages.

Service Innovation and Value-Co-creation

Service innovation has several dimensions. Service innovation can come about through the creation of a service concept which is sufficiently different that it is not merely an improved service, but in reality is a new service concept. To maintain the rigor and value of innovation, it is necessary to distinguish between an improved service, which may generate some additional value, and a truly new and innovative service concept, which may generate a great deal of value. Dr. Noriaki Kano, a renowned quality management guru, has suggested that every service concept has its inherent attributes and we should strive to continuously improve upon these; but this is not innovation (Kano 1996).

To be innovative, the change in a value proposition cannot be incremental, but it must be enough to significantly impact customer and competitor behavior (e.g., new market creation). Value innovation involves a shift in perspective of customer needs that requires a rethinking of what service value proposition is delivered (Kano 1996).

Innovation can also come through a significant change in the way or the reason the customer is engaged or connected. In a service value chain the customer may well change from being just a receiver of service value to becoming a co-creator, or an active participant in the design and delivery, i.e., service transaction of service value. At the retail level, when a customer designs the time, route, and price selection for a plane ticket purchased online, he is co-creating the service. Value innovation involves a shift in perspective of customer needs that requires a rethinking of how a service value proposition is delivered (Bettencourt 2010).

Finally, service innovation can come through significant changes in the way the enterprise is organized to create a service value proposition from concept through delivery. A considerable improvement in the enterprise structure and/or governance can be seen as innovation. Value innovation involves a shift in perspective of customer needs that requires a rethinking of how an enterprise organizes to support a service value proposition.

Continuous improvement can be reasonably planned and predicted while innovation and breakthroughs cannot. The most effective way to obtain innovation and breakthroughs is to encourage the culture, environment, and atmosphere that are conducive to innovation and breakthroughs. Innovative co-creation requires the integration of people, ideas, and technology for the purpose of creating value for themselves, their customers, companies, and society.

The lone inventor sees a problem and must work to create the solutions to all dimensions of the problem. Co-creators see the problem and realize that there may already be several creators, each already having a piece of the solution. Co-creation embraces the value of things “not invented here” because of the velocity they can bring to ideation and time to market. This service innovation process is facilitated by modern mass (and at the same time, personal) communication technology evident in social networking platforms.

Towards a Discipline of Service Systems Engineering

Mindful of the evolution taking place in the global economy and the world markets, it would be futile to attempt covering all the major advances and the boundless possibilities in the services sector for the rest of the century. The services sector covers wide areas of application studied in many different fields (e.g., business science, social science, cognitive science, political science, etc.). The field of service systems, a trans-disciplinary analysis and study of services, was only introduced 10 to 15 years ago. As a consequence, much of the existing literature on services and service-innovation is scattered. The main objective of this KA is to document the systems engineering processes, methodologies, and existing tools as applied to the service design process, and to introduce critical SSE challenges and research areas.

Service Systems Background

-

Economies are pre-disposed to follow a developmental progression that moves them from heavy proportional reliance on agriculture and mining toward the development of manufacturing, and finally toward more service-based economic activity. As reported by the Organization for Economic Co-Operation and Development (OECD) in its “Science, Technology, and Industry (STI) Forum on The Service Economy":

> *The reason that we see a services economy today, and gather to talk about it and recognize its importance is because technology has allowed service industries to gain the operational leverage that manufacturing achieved 100 years ago. In addition to banks, health systems, telephone and telecommunications networks, and distribution and retailing firms are further examples of sectors that have been able to benefit from economies of scale. As a result, we are now living in a world where global-scale service companies exist for the first time, whereas we have seen global manufacturing companies for 50 years or more.* (OECD 2000, 8)

Evolution Toward Service-Based Economies

The typical industry example given of this progression toward services is the company International Business Machines (IBM). Even though IBM still produces hardware, they view their business as overwhelmingly service-oriented wherein hardware plays only an incidental role in their business solutions services; the fastest line of business growth within IBM has been the business-to-business (B2B) services: information technology (IT); for example, data centers and call centers; business process outsourcing/re-engineering; systems integration; and organizational change.

Business to government (B2G) is forecasted to have the fastest growth in the years to come (Spohrer 2011). For IBM, this trend started in 1989 with the launch of business recovery services; it accelerated with the acquisition of Price-Waterhouse Coopers Consultants in 2002 and culminated with the 2005 sale of the laptop (ThinkPad) manufacturing, their last major hardware operation.

IBM exemplifies the services trend which has accelerated in the last 25-30 years and as of 2006, the services produced by private industry accounted for 67.8% of U.S. gross domestic product (GDP). The top sub-sectors included real estate, financial, healthcare, education, legal, banking, insurance, and investment. Production of goods accounted for 19.8% of GDP. The top product sub-sectors included manufacturing, construction, oil and gas, mining, and agriculture (Moran 2006).

Beginning in the mid-1990s, the concept of a product-service system (PSS) started to evolve. PSSs have been adopted by businesses interested in using the model to bring not only added value to their existing offerings, but capital-intensive, environmentally favorable products to market (Mont and Tukker 2006).

There are some definitional issues in any discussion of PSS, including the fact that services can sometimes be considered as products, and services invariably need physical products to support their provisioning or delivery (2006). A PSS is comprised of tangibles and intangibles (activities) in combination to fulfill specific customer requirements, or ideally, to allow applications to be co-created flexibly by linking loosely coupled agents, typically over a network (Domingue et al. 2009). Research has shown that manufacturing firms are more amenable to producing "results" rather than solely products as specific artifacts and that end users are more amenable to consuming such results (Cook 2004; Wild et al. 2007).

The popularity of wikis, blogs, and social networking tools is strong evidence that "Enterprise 2.0" is already well under way; Andrew McAfee describes Enterprise 2.0 as "the use of emergent social software platforms within companies, or between companies and their partners or customers" (McAfee 2009). However, the integrated access to people, media, services, and things, provided by the Future Internet, will enable new styles of societal and

economic interactions at unprecedented scales, flexibility, and quality. These applications will exploit the wisdom of crowds and allow for mass collaboration and value co-creation.

The future internet will provide location independent, interoperable, scalable, secure, and efficient access to a coordinated set of services (Tselentis et al. 2009), but such a broad vision demands a sound and well-defined approach for management and governance.

Current application service providers like Amazon, Facebook, Twitter, eBay, and Google must mediate between the business challenges enabled by network and IT convergence and customers (enterprise or consumer) demanding new and more value-adding services enabled by social networks (TMFORUM 2008). The differences between IT and communications technologies are disappearing; internally-focused processes (back-stage processes) for operations optimization are now being strongly tied to the customer facing (front-stage) processes for value co-creation and delivery. In this scenario, the enterprise's internal organization and employees are embedded in the service value chain to benefit customers and stakeholders. In the service-dominant logic (S-DL) for marketing (Vargo and Lusch 2004), service is the application (through deeds, processes, and performances) of specialized operant resources (knowledge and skills) for the benefit of another entity or the entity itself. The emphasis is on the process of doing something for, and with, another entity in order to create value; a service system is thus a system of interacting and interdependent parts (people, technologies, and organizations) that is externally oriented to achieve and maintain a sustainable competitive advantage (IFM 2008; Maglio and Spohrer 2008).

The future internet is expected to be more agile, scalable, secure, and reliable, demanding rapidly emerging applications/services with different requirements and implications for the Future Internet design that pose a significant set of problems and challenges, in particular, "the fragmentation of knowledge and the isolation of the specialist as well as the need to find new approaches to problems created by earlier 'solution of problems,'" (Skyttner 2006). The service systems engineering discipline may inform the discussion and offer potential multidisciplinary environments and trans-disciplinary solutions.

The internet has been successfully deployed for several decades due to its high flexibility in running over different kinds of physical media and in supporting different high-layer protocols and applications, including traditional file transfer, email, and client-server-based Web applications, among others.

Business Dependence on Service Systems

Most people and enterprises are heavily dependent on service interactions, including entertainment, communications, retail, education, healthcare, etc., brought about by emerging services, such as video on demand, web conferencing, time-shift services, place-shift and device-shift services, enterprise applications (e.g., enterprise resource planning (ERP), customer relationship management (CRM), manufacturing resource management (MRM), software configuration management (SCM), etc.), software as a service (SaaS), platform as a service (PaaS), cloud services, peer-to-peer (P2P) services, etc. A common denominator in the set of services mentioned is that applications are offered as services by the interaction of service system entities and thus they are service based applications (SBA).

Thus, "A service based application is obtained by composing various service system entities to satisfy the desired functionality" (Andrikopoulos et al. 2010). SBAs are heavily dependent on web services development, such as Web services 2.0 (WS). Software systems engineering (SwSE) plays a very important role in a business dependent on a service system. However, another important role is played by human interfaces, organizational development and technology development; for instance, governance (rules & regulations) and technology research and development are required for future services in healthcare services, intelligent transportation services, environmental services, energy services, etc. to address societal challenges of the 21st century (sustainability, energy, etc.) as presented by (Vest 2010) if we were to face those challenges as an ecosystem.

Service System Example

In an intelligent transport system-emergency transportation operation (ITS-ETO), the service goal is to provide safe evacuation, prompt medical care, and improved emergency management service. Typically, a traveler can request service through an emergency call or automated crash report feature, or a public safety officer on location can request service based on customer features and access rights.

The ITS-ETO service system utilizes advances in communication and information systems (technology and information enabler) to access essential, real-time data about conditions on routes throughout the affected area and coordinate operational and logistical strategies in cooperation within all service entities (organization processes). In a critical emergency situation, when patient conditions are continuously changing, ITS can help identify the appropriate response and get the correct equipment (infrastructure enabler), such as a helicopter and emergency personnel (people enabler), to and from the scene quickly and safely.

Efficient and reliable voice, data, and video communications (application enabler) further provide agencies with the ability to share information related to the status of the emergency, the operational conditions of the transportation facilities, and the location of emergency response resources to help communicate and coordinate operations and resources in real time. Advances in logistical and decision-making tools can enable commanders and dispatchers to implement strategies as conditions change (decision making).

It is also critical to receive information on the environmental conditions (storm, hazardous materials, multi-vehicle crashes, etc.) and/or road closures when coordinating evacuations. The availability of real-time data about transportation conditions, coupled with decision-making tools, enables more effective responses and coordination of resources during emergencies. ITS-ETO also enhances the ability of transportation agencies to coordinate responses with other stakeholders/entities.

As a result, increased data accuracy, timeliness, and automation leads to better use of resources, and reuse of exchanges, resulting in time and cost savings. Enhanced response and management leads to greater situational awareness and more effective reactions with the ability to identify and utilize the appropriate equipment, resulting in a more efficient response at the right time (output) (US DOT 2011). Figure 1 below lists the possible stakeholders in a service system.

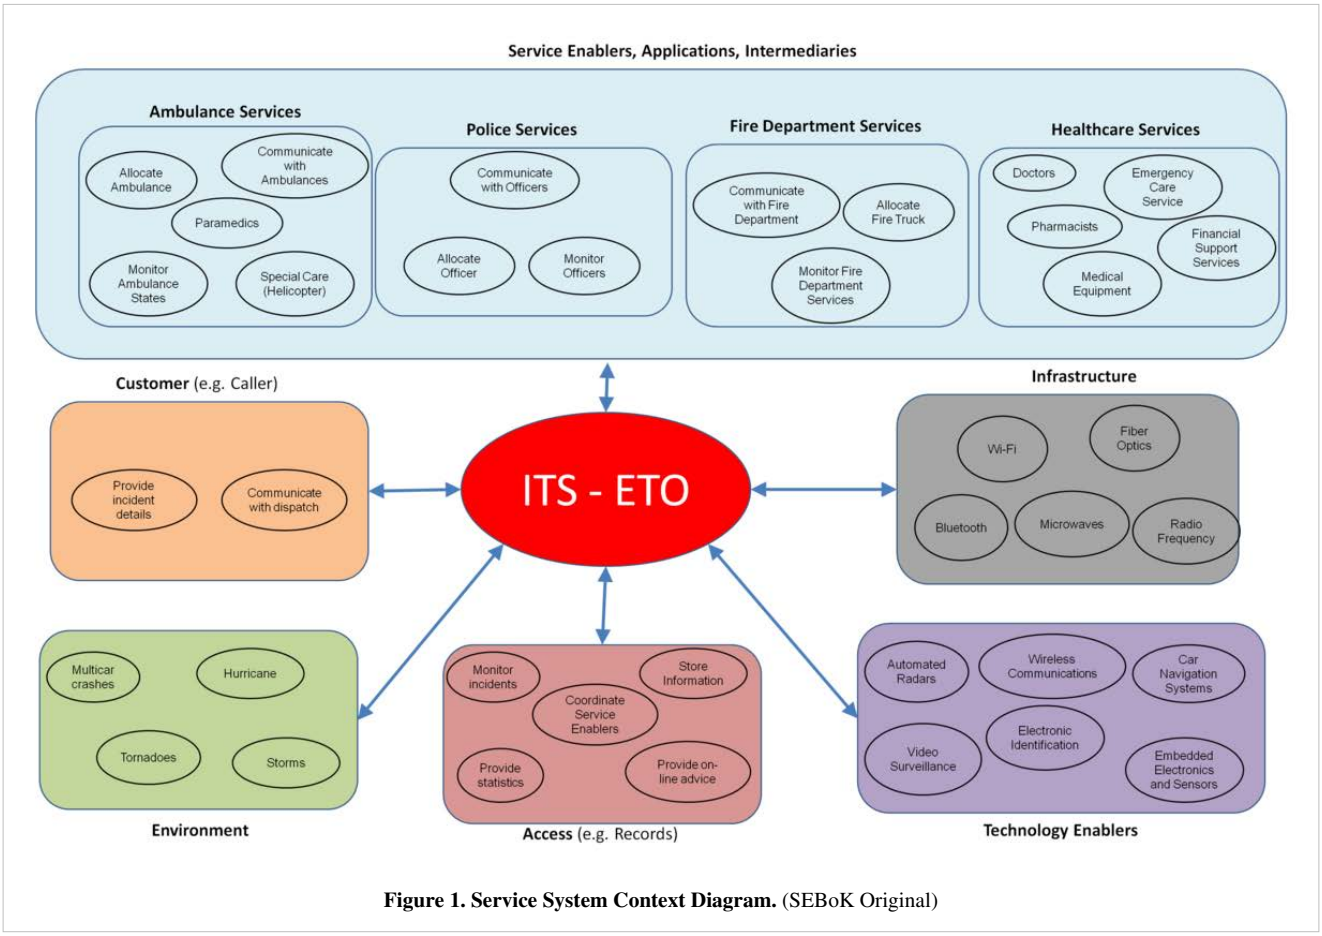

Figure 1. Service System Context Diagram. (SEBoK Original)

As seen in the above example, the service activities are knowledge-intensive; well defined linkages (including access rights) and relationships among different entities give rise to the needed service systems interactions for the service system to be successful. As the world becomes more widely interconnected, and people become better educated, the services networks created by the interaction of the service systems will be accessible from anywhere, at any time, by anyone with the proper access rights.

Knowledge agents are then humans creating new linkages of information to create new knowledge which “can later be embedded in other people, technology, shared information, and organizations." Thus, people can be considered as individual service systems with “finite life cycles, identities (with associated histories and expectations), legal rights and authority to perform certain functions, perform multitasking as a way to increase individual productivity output in a finite time, and engage in division-of-labor with others to increase collective productive output in finite time” through service transactions enabled by their access rights (Spohrer and Kwan 2008).

Fundamentals of Services

- Lead Author:
- Ricardo Pinedaж Bud Lawson

-

Services are activities that cause a transformation of the state of an entity (a person, product, business, region, or nation) by mutually agreed terms between the service provider and the customer. Individual services are relatively simple, although they may require customization and significant back-stage support (e.g., database, knowledge management, analysis, forecasting, etc.) to assure quality and timely delivery. Product services are also relatively straightforward as product specifications, performance standards, quality control, installation guidelines, and maintenance procedures require good communication and understanding between providers and users. Business services can be rather complex; some may involve intensive negotiations, work process alignment, quality assurance, team collaboration, and service coproduction. Moreover, Chang (2010) states that: "Regional and National services are even more complex, as they may affect policy, custom regulations, export permits, local business practices, logistics, distribution, and other such issues" (see also Complexity).

Service Systems

The service and/or set of services developed and accessible to the customer (individual consumer or enterprise) are enabled by a service system. Service system stakeholders may interact to create a particular service value chain to be delivered with a specific objective (Spohrer and Maglio 2010). Service system entities dynamically configure four types of resources: people, technology/environment infrastructure, organizations(glossary)/institutions, and shared information/symbolic knowledge. Service systems can be either formal or informal in nature. In the case of formal service systems, the interactions are contracted through service level agreements (SLA). Informal service systems can promise to reconfigure resources without a written contractual agreement; in the case of the emergency transports operations example discussed in the Service Systems Background article, there is no formal contractual agreement (i.e., SLA) between the user requesting the service and the agency providing the service other than a "promise" for a quick and efficient response. SLAs are written contracts between and among service system entities, as well as the legal system for enforcing the contracts. The study of informal service systems contains the study of relationships (communications, interactions, and promises) between service systems and social systems, cultural norms and beliefs, as well as political systems that can maintain those relationships (Spohrer and Kwan 2008). The resources are either physical or non-physical and have rights or no rights. See Figure 1 below:

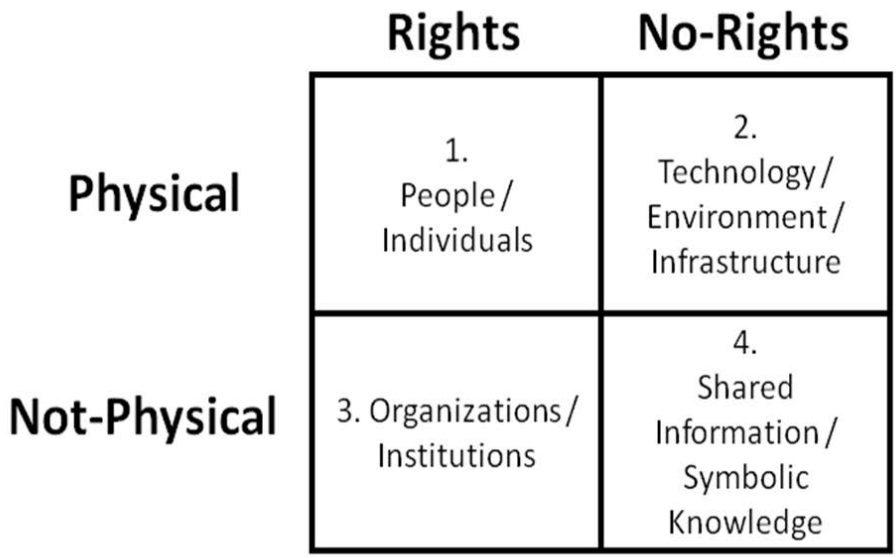

Figure 1. Service System Resources (Spohrer 2011). Reprinted with permission of Dr. James C. Spohrer. All other rights are reserved by the copyright owner.

Service Value Chain

SLAs and policies specify the conditions under which services system entities reconfigure access rights to resources by mutually agreed value propositions. Current management frameworks typically focus on single service system entity interfaces. They neither use SLAs for managing the implementation and delivery of services nor do they recognize/support the fact that many services may be composed of lower-level services, involve third-party providers, and rely on possibly complex relationships and processes among participating businesses, information communications, and technologies (CoreGRID 2007). While SLAs are mapped to the respective customer requirements, policies are provider-specific means to express constraints and rules for their internal operations. These rules may be independent of any particular customer (Theilmann 2009).

In service systems practice, we describe the service value chain in terms of links among the entities connected via the Network Centric operations of service systems. For instance, value could then be created and delivered in terms of e-services, such as business-to-business (B2B), business to consumer (B2C), business to government (B2G), government-to-business (G2B), government-to-government (G2G), government-to-consumer (G2C), etc. The emerging service in this case interacts or “co-produces” with their customer via the World Wide Web as compared to the physical environment in which the traditional, or brick and mortar, service enterprises interact with their customers.

The services sector requires information as input, involves the customer at the production/delivery stage, and employs mostly qualitative measures to assess its performance, i.e., technology-intensive services are “information-driven, customer centric, e-oriented, and productivity-focused" (Tien and Berg 2003; Hipel et al. 2007; Chesbrough 2011). Chang (2010) defines these features in this manner:

- **Information Driven:** The creation, management, and sharing of information is crucial to the design, production, and delivery of services.
- **Customer Centric:** Customers are generally the co-producer of the services, as in the case of self-service. Customers require a certain degree of self-adaptation or customization and customers must be satisfied with the rendered services.

- **E (electronics) Oriented:** Services are becoming increasingly e-oriented. Thus, e-access, e-commerce, and e-customer management are crucial to e-services.
- **Productivity Focused:** Both efficiency and effectiveness are important in the design, delivery, and support of services.
- **Value Adding:** Services need to provide some value for the target clients. For profit-seeking service companies, the value produced for customers assures the company's profitability. For non-profit service entities, the value produced for customers reinforces the quality of a service entity's policy.

A service system is defined by its value co-creation chain in which stakeholders work in open collaboration to deliver consistently high quality service according to business goals, service goals, and customer goals. A value proposition can be viewed as a request from one service system to another to run an algorithm (the value proposition) from the perspectives of multiple stakeholders according to culturally determined value principles. The four primary stakeholder's perspectives in regards to value are the customer, provider, authority, and the competitors. Figure 2 below depicts value calculations from multiple stakeholder perspectives.

Table 1. Value Calculation from Different Stakeholders' Perspectives (Spohrer 2011). Reprinted with permission of Dr. James C. Spohrer. All other rights are reserved by the copyright owner.

Stakeholder Perspective (the players)	Measure Impacted	Pricing Decision	Basic Questions	Value Proposition Reasoning
1. Customer	Quality (Revenue)	Value Based	Should we? (offer it)	Model of customer: Do customers want it? Is there a market? How large? Growth rate?
2. Provider	Productivity (Profit, Mission, Continuous Improvement, Sustainability)	Cost Plus	Can we? (deliver it)	Model of self: Does it play to our strengths? Can we deliver it profitability to customers? Can we continue to improve?
3. Authority	Compliance (Taxes and Fines, Quality of Fire)	Regulated	May we? (offer and deliver it)	Model of authority: Is it legal? Does it compromise our integrity in any way? Does it create a moral hazard?
4. Competitor (Substitute)	Sustainable Innovation (Market Share)	Strategic	Will we? (invest to make it so)	Model of competitor: Does it put us ahead? Can we stay ahead? Does it differentiate us from the competition?

From an engineering design point of view, the service and business goals are an entry point through which to analyze the business architectures (including organization and processes) needed, which in turn demand alignment between the information technology (IT) components and technology architecture to achieve the goals. From a systems engineering perspective, the next step is to identify service system entities that could participate in the service delivery (people, organizations, technologies, processes, etc.).

Service System Entities

Spath and Fahnrich (2007) defined a service meta-model comprised of nine types of **entities**:

1. **Customers**: customer features, customer attitudes, and customer preferences;
2. **Goals**: business goals, service goals, customer goals, and enterprise culture goals;
3. **Inputs**: physical, human beings, information, knowledge, currency, and constraints;
4. **Outputs**: physical, human beings, information, knowledge, currency, and waste;
5. **Processes**: service provision, service operations, service support, customer relationships, planning and control, and call center management;
6. **Human Enablers**: service providers, support providers, management, and owner organization (enterprise);
7. **Physical Enablers**: owner organization (physical), buildings, equipment, furnishings, and location;
8. **Informatics Enablers**: information, knowledge, procedures and processes, decision support, and skill acquisition; and
9. **Environment**: political factors, economic factors, social factors, technological factors, environmental factors, legal factors (PESTEL), and physical factors.

Thus, a service or service offering is created by the relationships among service system entities (including information flows) through business processes into strategic capabilities that consistently provide superior value to the customer. If we were to represent the service as a network diagram (as in Figure 3 below), then the entities represent the nodes and the links represent the relationships between nodes.

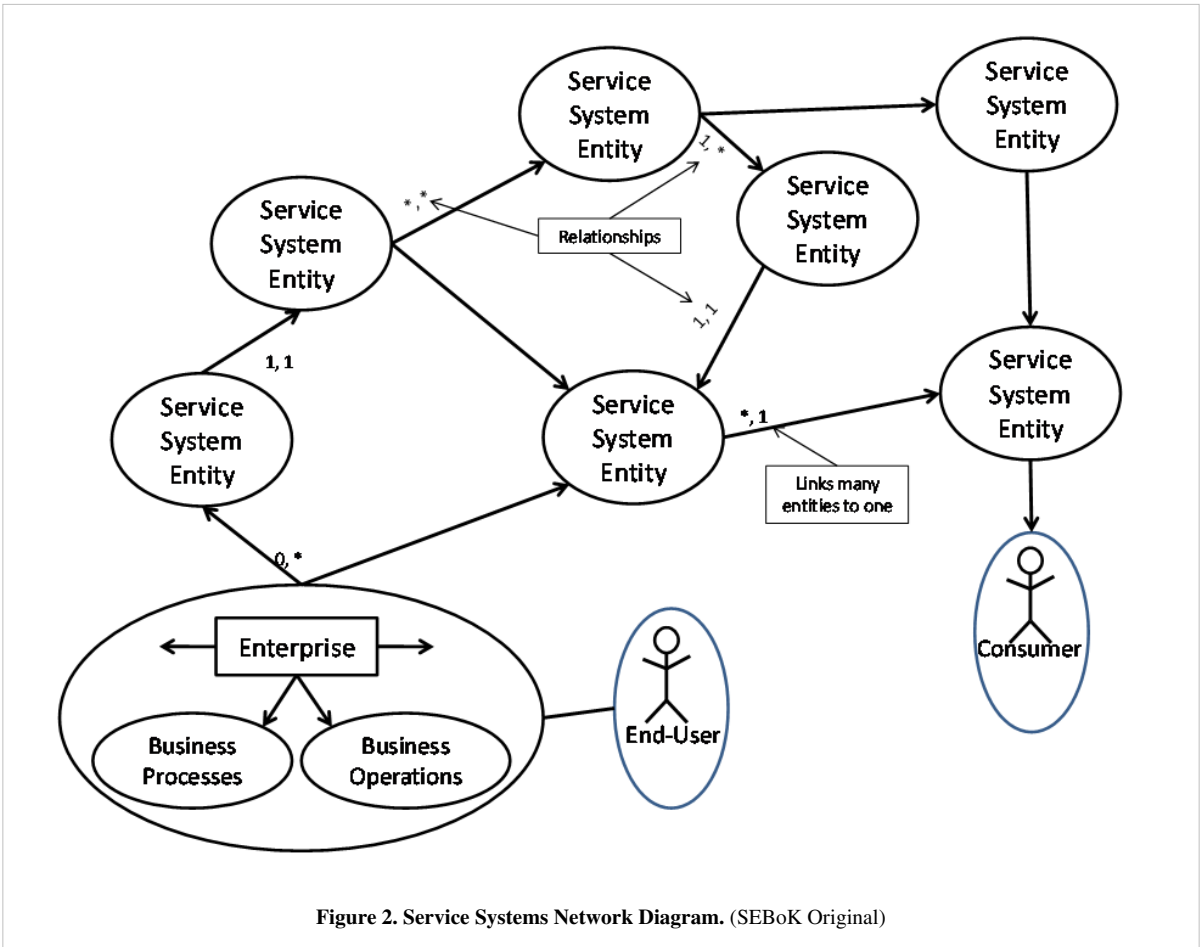

Figure 2. Service Systems Network Diagram. (SEBoK Original)

Service System Hierarchy

Systems are part of other systems which are often expressed by systems hierarchies (Skyttner 2010) to create a multilevel hierarchy, and thus the service system is composed of service system entities that interact through processes defined by governance and management rules to create different types of outcomes in the context of stakeholders with the purpose of providing improved customer interaction and value co-creation. Examples of service system entities are business enterprises, nations, or in the simplest form, a person (consumes and produces services).

Using the hierarchical approach, Spohrer conceptualizes an ecosystem at the highest level in which a service system is an entity of its own. This concept is extended to create the service system hierarchy as described in Figure 4 below (Spohrer 2011; Maglio and Spohrer 2008; Maglio et al. 2010).

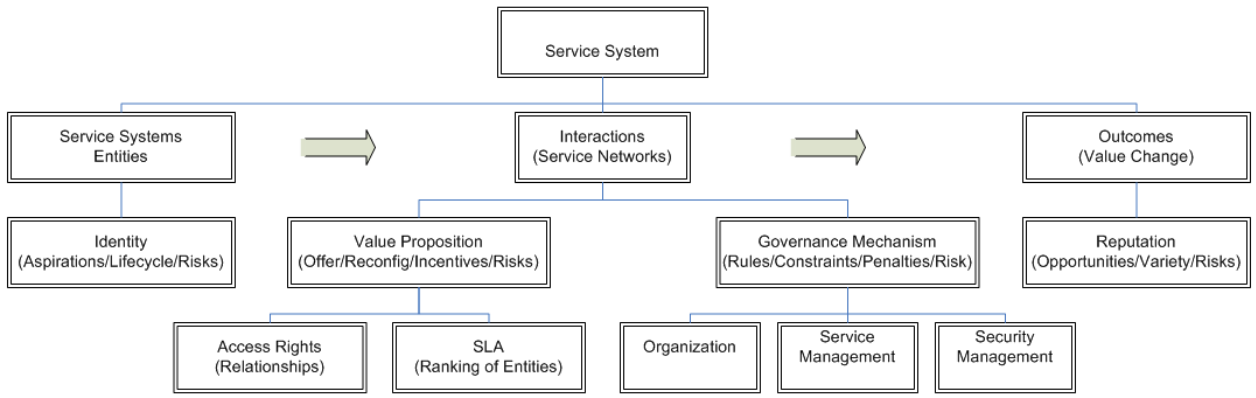

Figure 3. Service System Conceptual Framework (Spohrer 2011). Reprinted with permission of Dr. James C. Spohrer. All other rights are reserved by the copyright owner.

Service System Attributes

The fundamental attributes of a service system include togetherness, structure, behavior, and emergence. As mentioned earlier, today's global economy is very competitive and a service system may be very competitive in a given environment at a given time (the business space). The service system's trajectory should be well controlled as time goes by (Qiu 2009) since services are "real time in nature and are consumed at the time they are co-produced" (Tien and Berg 2003), that is, during service transactions.

The service system should evolve and adapt to the conditions within the business space in a manner which ensures that the customized service behaves as expected. This adaptive behavior of service systems implies that their design must be truly trans-disciplinary:

> *They must include techniques from social science (i.e., sociology, psychology, and philosophy) and management (i.e., organization, economics, and entrepreneurship). As a consequence, Systems, Man, and Cybernetics (SMC) must expand their systems (i.e., holistic oriented), man (i.e., decision-oriented), and cybernetics methods to include and be integrated with those techniques that are beyond science and engineering.* (Hipel et al. 2007)

Properties of Services

- Lead Authors:
- Ricardo Pineda, Bud Lawson, and Brian Wells

-

A service is realized by the service system through the relationships of service system entities that interact (or relate) in a particular way to deliver the specific service via a service level agreement (SLA). Current management frameworks typically only focus on the interfaces of single service system entities. Meanwhile, SLAs are mapped to the respective customer requirements. These policies are provider-specific means to express constraints and rules for their internal operations. These rules may be independent of any particular customer (Theilmann 2009).

Services not only involve the interaction between the service provider and the consumer to produce value, but have other attributes, like an intangible quality of service (e.g., an ambulance service's availability and response time to an emergency request). The demand for a service may have varying loads dependent on the time of day, day of week, season, or other unexpected needs (e.g., natural disasters, product promotion campaigns, etc.). In the US for instance, travel services have peak demands during Christmas week; Mother's day is usually the highest volume handling day for a telecommunications provider and tax services peak during extended periods (January through mid-April). Services cannot be inventoried; they are rendered at the time they are requested.

Additionally, for a business enterprise, delivering the service at the minimum cost while maximizing its profits may be the service objective. In contrast, for a non-profit organization the objective may be to maximize customer satisfaction while optimizing the resources required to render the service (e.g., during a natural disaster). Thus, the design and operations of service systems "is all about finding the appropriate balance between the resources devoted to the systems and the demands placed on the system so that the quality of service to the customer is as good as possible" (Daskin 2010).

Service Level Agreement

A SLA is a set of technical (functional) and non-technical (non-functional) parameters agreed among customers and service providers. SLAs can and do contain administrative level (non-functional) business related parameters, such as SLA duration, service availability for the SLA duration, consequences for variations, failure reporting, priorities, and provisions for modifications to the SLA. However, for service level management, the service level (technical) parameters need to be defined, monitored, and assessed; these parameters may include such things as throughput; quality; availability; security; performance; reliability, for example, mean time between failure (MTBF), maximum downtime, and time-to-repair; and resource allocation.

An SLA represents the negotiated service level requirements (SLR) of the customer and should establish valid and reliable service performance measures since it is usually the basis for effective service level management (SLM). The goal of SLM is to ensure that service providers meet and maintain the prescribed quality of service (QoS). However, care should be taken since in some domains the term QoS refers only to resource reservation control mechanisms rather than the achieved service quality (e.g., internet protocol (IP) networks). Some terms used to mean the "achieved service quality" include quality of experience (QoE), user-perceived performance, and degree of satisfaction of the user; these other terms are more generally used across service domains.

Non-functional properties fall into two basic categories: business properties, such as price and method of payment, and environmental properties, such as time and location. Business and environmental properties are classified as "context properties" by Youakim Badr (Badr et al. 2008). QoS properties are characteristics such as availability, resilience, security, reliability, scalability, agreement duration, response times, repair times, usability, etc. Therefore services evaluation measures are customer oriented and include not only traditional performance metrics (productivity, quality, etc.), but also require a comprehensive analysis of the service system from an end-to-end

perspective. Service evaluation typically includes customer demand-supply to ensure economic viability across the lifecycle of the service system. Furthermore, the service delivery is evaluated using the key technical performance metrics listed above, adding also Service Process Measures (provisioning time, time-to-restore/repair, etc.) and Technical Performance Measures (end-to-end response times, latency, throughput, etc.). Finally, the service system's SLAs are then the composition of these categories evaluated on a systemic level to ensure consistency, equity, and sustainability of the service to assure that the desired/contracted SLA for customer satisfaction, value co-creation, and high system robustness are realized. (Spohrer 2011; Tien and Berg 2003; Theilmann and Baresi, 2009)

Service Key Performance Indicators

Service key performance indicators (KPI) are defined and agreed to in the SLA; the service KPIs are decomposed into service process measures (SPM) and technical performance measures (TPM) during the analysis stage of the service systems engineering (SSE) process. In the design process, the KPIs and TPM are allocated to service system entities and their components, as well as to the business processes and their components so as to ensure compliance with SLAs. The allocated measures generate derived requirements (SLR) for the system entities and their relationships, as well as for the service entities' components and the data and information flows required in the service systems to monitor, measure, and assess end-to-end SLA. These allocations ensure that the appropriate performance indicators apply to each of the links in the service value chain.

TPMs are typically categorized by the number of defective parts in a manufacturing service, data transmission latency and data throughput in an end-to-end application service, IP QoS expressed by latency, jitter delay, and throughput; SPMs are typically categorized by service provisioning time, end-to-end response times to a service request (a combination of data and objective feedback), and quality of experience (QoE verified by objective feedback). Together, the KPI (TPM combined with SPM) and perception measures make up the service level management function. A quality assurance system's (QAS) continuous service improvement (CSI), processes, and process quality management and improvement (PQMI) should be planned, designed, deployed, and managed for the capability to continuously improve the service system and to monitor compliance with SLAs (e.g., PQMI, capability maturity model integration (CMMI) (SEI 2007), International Organization for Standardization (ISO) Standards 9001 (ISO/IEC 2008), Telecom Quality Management System Standards (TL 9000) (QuEST Forum 2012), Information Technology Infrastructure Library (ITIL) v. 3 (OGC 2009), etc.).

As discussed earlier, QoS needs to correlate customer perceived quality (subjective measures) with objective SPM and TPM measures. There are several techniques available to help monitor, measure, and assess TPM's, but most are a variation on the theme of culling information from TPM's using, for example, perceptual speech quality measure (PSQM) and perceptual evaluation of video quality (PEVQ) and enhancing or verifying this information with customer or end-user perception of service by extending mean opinion score (MOS) techniques/customer opinion models (Ray 1984). Telecommunication systems engineering (TCSE) played an important role in finding methodologies for correlation between perception and objective measures for the services of the twentieth century; SSE should continue to encourage multidisciplinary participation to equally find methodologies, processes, and tools to correlate perceived service quality with TPM and with SPM for the services of the twenty-first century (Freeman 2004).

Subjective (qualitative) service quality is the customer's perceived conformity of the service with the expected objective. Word-of-mouth, personal needs, and past experiences create customer expectations regarding the service. The customers' perception of the service must be captured via surveys and interviews. The customers' perception of the service is then compared with their expectations for the service; this process captures the perceived service quality. Care should be taken to understand that subjective measures appear to measure customer attitudes, and attitudes may be the result of several encounters with the service, as well as numerous encounters with similar services.

In summary, the SLA documents the SLRs and establishes reliable and valid service performance measures, technical parameters, and the agreed performance levels for the technical parameters. The technical parameters are then monitored and continuously compared against both objective and subjective data culled from multiple internal and external sources (service level management). The goal is not to report the level of service in a given period, but to develop and implement a dynamic system capable of predicting and driving service level improvement over time (i.e., continual service improvement (CSI)).

Evolution of Services

The second, third, and fourth decades of the twenty-first century will almost certainly see similar, and probably accelerated, technology development as seen in the prior three decades. Mass collaboration will become an established mode of operation. The beginnings of mass collaboration have manifested in developments such as value co-creation where loosely entangled actors or entities come together to create value in unprecedented ways, but ways that meet mutual and broader market requirements. Further developments in the technology, use, and acceptance of social media will continue to fuel the acceleration of these developments.

The next decades will see the grounding of concepts, such as crowdsourcing, coined by Jeff Howe in a June 2006 *Wired* magazine article; open innovation, promoted by Henry Chesbrough, a professor and executive director at the Center for Open Innovation at Berkeley; and mass collaboration and open source innovation supported by Enterprise 2.0 tools, as conceived by Wikinomics consultant Don Tapscott.

Roberto Saracco, a telecommunications expert specializing in analyzing economical impacts of technology evolution, argues that: "Communications will be the invisible fabric connecting us and the world whenever and wherever we happen to be in a completely seamless way, connecting us so transparently, cheaply, and effortlessly that very seldom will we think about it." The ubiquity and invisibility of these communications will greatly facilitate the creation and destruction of ad hoc collectives (groups of entities that share or are motivated by at least one common issue or interest, or work together on a specific project(s) to achieve a common objective). This enterprise may engender the concept of the hive mind (the collective intelligence of many), which will be an intelligent version of real-life super organisms, such as ant or bee nests (Hölldobler and Wilson 2009).

These models will most certainly give rise to issues of property rights and liabilities; access rights for both the provider and the customer can be owned outright, contracted/leased, shared, or have privileged access (Spohrer 2011). For now, we are on the cusp of a management revolution that is likely to be as profound and unsettling as the one that gave birth to the modern industrial age. Driven by the emergence of powerful new collaborative technologies, this transformation will radically reshape the nature of work, the boundaries of the enterprise, and the responsibilities of business leaders (McAfee 2009).

The service-providing industry in the US is divided into thirteen sectors (Chang 2010):

1. professional and business services,
2. healthcare and social assistance,
3. state and local government,
4. leisure and hospitality,
5. other services,
6. educational services,
7. retail trade,
8. financial activities,
9. transportation and warehousing,
10. wholesale trade,
11. information,
12. federal government, and
13. utilities.

Spohrer (2011) goes beyond the service sectors to propose three types of service systems:

1. ***Systems that focus on flow of things***: transportation and supply chains, water and waste recycling, food and products, energy and electric Grid, information/ICT & cloud;
2. ***Systems that focus on Human Activities and Development***: buildings and construction, retail and hospitality / media and entertainment industries, banking and finance / business consulting industries, healthcare and family life systems, education and work life / jobs and entrepreneurship; and
3. ***Systems that focus on Governing***: cities, states, and nations.

Categorizing types and sectors of services is an important beginning because it can lead to a better understanding of the emerging rules and relationships in service value chains. This approach can further enhance the value co-creation capabilities of innovative service concepts that contribute to our quality of life. The classification also helps in identifying different objectives and constraints for the design and operations of the service system. Some examples include strategic policies under limited budget: education, strategic with readiness for quick response; national defense; business enterprise, maximizing profit while minimizing cost; etc.

In addition, this classification is being used to determine the overlap and synergies required among different science disciplines to enable trans-disciplinary collaboration and educational programs.

Scope of Service Systems Engineering

- Lead Authors:
- Ricardo Pineda and Bud Lawson

-

Service systems engineering (SSE) involves all aspects of the enterprise. This topic discusses different aspects of the scope of SSE, from organizational strategy, to interoperability, to the life cycle of services, and then to their design.

SSE and the Enterprise

Enterprises plan, develop, and manage the enhancements of their infrastructure, products, and services, including marketing strategies for product and service offerings. These plans propose new products or service offerings based on new, unexplored, or unforeseen customer needs with clearly differentiated value propositions. Service strategies are the internal business processes required to design, operate, and deliver services. The mission of service strategies is to develop the capacity to achieve and maintain a strategic advantage (OGC 2009).

Taking the systems engineering (SE) approach to service systems, or (SSE), is imperative for the service-oriented, customer-centric holistic view to select and combine service system entities. The SSE approach can then define and discover relationships among service system entities to plan, design, adapt, or self-adapt to co-create value. The SSE approach should identify linkages, relationships, constraints, challenges/problems, new technologies, interoperability standards, interface agreements, or process development requirements among service entities required for the planned service or for potential future services (Lefever 2005).

SSE mandates participation not only from engineering, business operations, and customers, but also from various different domains, such as management science, behavioral science, social science, systems science, network science, computer science, decision informatics, etc.

Hipel et al. (2007) have presented a table for service science in terms of the domains and methods, including not only service systems, but also infrastructure and transportation systems, environmental and energy systems, and defense and space systems. The collaboration domains in Figure 1 below are a first approximation to the collaboration required from different disciplines for the SSE paradigm.

Table 1. Service Systems Engineering Domain Collaboration. (Hipel et al. 2007) Reprinted with permission of © Copyright IEEE - All rights reserved.

SEE	Collaboration Domains
SSE Management	• Management Science • Business Process Management • Cognitive Science • Decision Science
Service Realization Process (SRP)	• All engineering fields • Business Operations • Infrastructure Operations • Social Science • Computer Science • Management Science • Behavioral Science • Network Science • Computational Science • Systems Science • Decision Science
Methodologies, Processes, and Tools (MPT)	• Natural Science • Business Science (BPMN) • Mathematical • All engineering fields

Major challenges faced by SSE include the dynamic nature of service systems evolving and adapting to constantly changing operations and/or business environments, and the need to overcome silos of knowledge. Interoperability of service system entities through interface agreements must be at the forefront of the SSE design process for the harmonization of operations, administration, maintenance, and provisioning procedures of the individual service system entities (Pineda 2010).

In addition, service systems require open collaboration among all stakeholders, but recent research on mental models of multidisciplinary teams shows integration and collaboration into cohesive teams has proven to be a major challenge (Carpenter et al. 2010) (See also Team Dynamics). Thus, the emphasis on multidisciplinary (e.g., scientific, engineering, management, and social) education and training programs required to foster systems thinking helps bridge the gaps created by these silos of knowledge.

In the SSE approach, the social, governance, business, service, operations, and management activities are linked together through the service life cycle; service systems are by themselves a type of system of systems (SoS) where traditional systems engineering (TSE) practices need to be extended to include service systems entities' relationships (e.g., interface agreements among people, organizations, processes, and technologies) through information flows, technical interoperability, governance, and access rights within a system of systems.

Interoperability of Services

Interoperability among the different service system entities becomes highly relevant in SSE since the constituent entities are designed according to stakeholder needs; the entity is usually managed and operated to satisfy its own objectives independently of other system entities. The objectives of individual service system entities may not necessarily converge with the overall objectives of the service system. Thus, the need to include the following in the definition of a service system: analysis and design of the service system, governance frameworks to align political objectives, service strategies, business objectives, information and communications technologies (ICT) objectives, technology objectives and end-to-end operations, administration and maintenance procedures, and allocation of these procedures to individual entities (Luzeaux and Ruault 2010).

The previous discussion relates to a new service system development. There may be instances where a service is planned for delivery in phases of deployment (transition/deployment phase), or as presented earlier, if there is already a service system defined and deployed, then it's possible that the new request is for a service based application (SBA), in which case, the process is more focused on the adaptations needed to deploy the new application. For SBA, instances of advances in computer engineering, computer science, and software development already permit the adaptation and creation of SBA in a run-time environment for the discovery, development, and publishing of applications (Maglio et al. 2010).

The service design process (SDP) for new services is triggered by the market concept of the intended service and considers the stakeholder(s), service value chain(s), target market(s), target customer(s), proposed SLA, demand forecast, pricing strategy, and customer access privileges, which together comprise the service strategy. The SDP process then adapts the TSE as a life cycle approach (concept/definition, design/development, deployment/transition, operations, life cycle management/utilization/CSI, and retirement) as discussed in Life Cycle Models. A more detailed list of the SSE process activities is described in Value of Service Systems Engineering and Service Systems Engineering Stages.

Service Lifecycle Stages

The SDP stages and notation are depicted in Table 2 below; due to the complexity of service systems (see also Complexity) the documents generated are becoming more model-based electronic documents than written binders depending on the methodologies and tools used.

Table 2. Service Realization Process: Life Cycle Stages. (SEBoK Original)

<html>

Life Cycle Changes		Purpose	Decision Gates
Service Strategy/Concept	New Service identification	*Elicit enterprise needs* *Explore service concepts* *Identify service system entities* *Propose viable HL black box solutions* ***Output: Service Description***	Decision Options - Go, No-GO - Continue this stage - Go to preceding stage - Hold project activity - Terminate project - Test - Deploy
	Feasibility Phase		
	HL Analysis		
Service Design/Development	Service Requirement Analysis and Engineering	*Refine service system requirements* ***Output: Service Requirement Document*** *Create solution description* *Identify Interfaces among entities* ***Output: Preliminary Design*** *Develop service system detailed architecture and specs* ***Output: Service Specification Document*** *Verify and Validate system requirements* ***Output: service JV & V Plans***	
	Service Development		
	Service Integration, Verification, and Validation		
Service Transition/Deployment		*Service Insertion Plans* *Deploy service system* *Manage deployment activities* *Inspect and test (verify)* ***Output: Service Operation Plans, Operations Technical Plans, Operational Readiness Plans***	
Service Operations and / Continuous Service Improvement		*Operate a reliable service system to satisfy customer needs* *Monitor, Measure, & Assess* *Provide sustained system capability* *Troubleshoot potential issues* *Store, archive, or dispose of the service system*	

</html>

All the life cycle stages are included for completeness, but very often during the concept analysis phase it may be determined that not all of the stages are needed. In these cases, a recommendation should be made regarding which stages are specifically required for the realization of the service in question.

Service Design Management

Another important role of SSE is the management of the service design process. SSE utilizes TSE practices to manage the resource and asset allocation to perform the activities required to realize the service through the value chain for both the customer and the service provider. The main focus of the service design process management is to provide for the planning, organizational structure, collaboration environment, and program controls to ensure that stakeholder's needs are met from an end-to-end customer perspective.

The service design process management process aligns business objectives and business operational plans with end-to-end service objectives, including customer management plans, service management and operations plans, and operations technical plans. The main SSE management activities are

- planning;
- assessment and control;
- decision management;
- risk management;
- configuration management; and
- information management.

SSE plays a critical role in describing the needs of the intended service in terms of the service's day-to-day operations, including customer care center requirements, interface among service system entities, such as: manufacturing plant, smart grid, hospital, network infrastructure provider(s), content provider(s) and service provider(s), service based application provider(s), applications providers, and the customer management process for the service.

Current research in computer engineering and software systems engineering is looking at the development of run-time platforms to allow real time or near real time customer service discovery and publishing (Spark 2009). The service-centric systems engineering (SeCSE) consortium has a well-defined service design process that is being applied to SBA. In this approach, there are design time and run-time sub-processes for the composition, provisioning, orchestration, and testing for service publishing (Lefever 2005). There is particular interest from the research community to include human-computer interactions (HCI) and behavioral science to address current social networking services (Facebook, Twitter, Linkedin, Google+, etc.) used to share unverified information via audio, messaging, video, chats, etc.

This research is gaining relevance because of the thin line between the customer (consumer, enterprise) and content providers in regards to security, privacy, information authentication, and possible misuse of the user-generated content. Even as the research progresses, these networking services are examples of business models organizing communities of interest for innovation. Hsu says, “If we understand this networking, then we may be able to see through the business strategies and systems design laws that optimize connected value co-creation” (2009).

Value of Service Systems Engineering

- Lead Authors:
- Ricardo Pineda, Bud Lawson, and Richard Turner

-

Service systems engineering (SSE) is a multidisciplinary approach to manage and design value co-creation of a service system. It extends the holistic view of a system to a customer-centric, end-to-end view of service system design. Service systems engineers must play the role of an integrator by considering the interface requirements for the interoperability of service system entities, not only for technical integration, but also for the processes and organization required for optimal customer experience during service operations.

Service systems engineering uses disciplined approaches to minimize risk by coordinating/orchestrating social aspects, governance (including security), environmental, human behavior, business, customer care, service management, operations, and technology development processes. Therefore, systems engineers must have a good understanding of cross disciplinary issues to manage, communicate, plan, and organize service systems development and delivery of service. Service systems engineering also brings a customer focus to promote service excellence and to facilitate service innovation through the use of emerging technologies to propose creation of new service systems and value co-creation.

The service design process includes the definition of methods, processes, and procedures necessary to monitor and track service requirements verification and validation, in particular as they relate to the operations, administration, maintenance, and provisioning procedures of the whole service system and its entities. These procedures ensure that failures by any entity are detected and do not propagate and disturb the operations of the service (Luzeaux and Ruault 2010).

Research on service systems needs to fuse business process management, service innovation, and social networks for the modeling of service system value chain (Carroll et al. 2010). The systems engineering approach helps to better understand and manage conflict, thereby helping both private and public organizations optimize their strategic decision making. The use of a systemic approach reduces rework, overall time to market, and total cost of development.

Service SE Knowledge & Skills

The world's economies continue to move toward the creation and delivery of more innovative services. To best prepare tomorrow's leaders, new disciplines are needed that include and ingrain different skills and create the knowledge to support such global services. "In this evolving world, a new kind of engineer is needed, one who can think broadly across disciplines and consider the human dimensions that are at the heart of every design challenge" (Grasso and Martinelli 2007).

Service systems engineers fit the T-shaped model of professionals (Maglio and Spohrer 2008) who must have a deeply developed specialty area, as well as a broad set of skills and capabilities (See the Enabling Individuals article). Chang (2010) lists the following twelve service system management and engineering (SSME) skills:

1. Management of Service Systems. These skills include scheduling, budgeting and management of information systems/technologies, and leadership;
2. Operations of Service Systems. Engineers should be proficient in process evaluation and improvement, quality improvement, customer relationships, and uncertainty management;
3. Service Processes. These skills include performance measurements, flow charting, work task breakdown;
4. Business Management. Business skills include project costing, business planning, and change management;
5. Analytical Skills. These skills include problem solving, economic decision analysis, risk analysis, cost estimating, probability and statistics;

6. Interpersonal Skills. Increasingly, service systems engineers are expected to excel in professional responsibility, verbal skills, technical writing, facilitating, and team building;
7. Knowledge Management. Service systems engineers should be familiar with definition, strategies, success factors, hurdles, and best practices in industry;
8. Creativity and Innovation in Services. These skills include creative thinking methods, success factors, value chain, best practices, and future of innovation;
9. Financial and Cost Analysis and Management. Additional business skills include activity-based costing, cost estimation under uncertainty, T-account, financial statements, ratio analysis, balanced scoreboards, and capital formation;
10. Marketing Management. Market forecast, market segmentation, marketing mix- service, price, communications and distribution- are important marketing tools;
11. Ethics and Integrity. Service Systems Engineers must be held to high ethical standards. These include practicing ethics in workplace and clear guidelines for making tough ethical decisions, corporate ethics programs, affirmation action, and workforce diversity, as well as global issues related to ethics. (See Ethical Behavior); and
12. Global Orientation. Increasingly, engineers must be aware of emerging business trends and challenges with regards to globalization drivers, global opportunities, and global leadership qualities.

Service Architecture, Modeling & Views

Successful deployment of service value chains is highly dependent on the alignment of the service with the overall enterprise service strategy, customer expectations, and customer's service experience. The importance of service-oriented customer-centric design has been recognized for several years by traditional service providers (telecommunications, information technology (IT), business reengineering, web services, etc.) through the creation of process-driven architecture frameworks.

Architecture frameworks are important for creating a holistic system view. They promote a common understanding of the major building blocks and their interrelation in systems of systems or complex systems of systems (see also Complexity). An architecture is a model of the the system created to describe the entities, the interactions and interoperability among entities, as well as the expected behavior, utilization, and properties of the end-to-end system. The architectures become the main tool to guide stakeholders, developers, third-party providers, operations managers, service managers, and users in the understanding of the end-to-end service system, as well as to enable governance at the service management and the service development levels.

These architecture frameworks have been defined through standards bodies and/or by private enterprises that recognize their advantage—standard processes that integrate the business-strategic processes and operations with the information technology and technology infrastructure (See Systems Engineering Standards). Most architecture frameworks model different scopes and levels of detail of business strategies, product and service offerings, business operations, and organizational aspects. Unfortunately, there are currently no frameworks that cover all the aspects (views) required to model the service systems. Some frameworks focus on business strategies, others in business process management, others in business operations, still others in aligning IT strategy or technology strategy to business strategy. Thus, a combination of architecture frameworks is required to create the enterprise service system model. For instance, an enterprise may use an enterprise business architecture (EBA) model covering strategic goals and objectives, business organization, and business services and processes where driven by market evolution, technology evolution, and customer demands. However, a reference framework would be needed to model the IT strategy (e.g., Information Technology Infrastructure Library (ITIL) v. 3 (OGC 2009)) and the organizations and processes needed to deliver, maintain, and manage the IT services according to the business strategy.

Service Architecture Frameworks

Prime examples of Service Architecture Frameworks are listed below.

Standards:

- Zachmann Framework (Zachman 2003)
- Business Process Modeling (BPM) (Hantry et al. 2010)
- The Open Group Architecture Framework (TOGAF) (TOGAF 2009)
- Enhanced-Telecomm Operations Map (eTOM) by the TeleManagemnt Forum (eTOM 2009)
- Service Oriented Architecture (SOA) (Erl 2008)
- National Institute of Standards and Technology (NIST) Smart Grid Reference Model (NIST 2010)
- Web services business process execution language (WS-BPEL) (OASIS 2007)
- Department of Defense Architecture Framework (DoDAF) (DoD 2010)
- Others.

Proprietary Enterprise Architecture Frameworks:

- Hewlett - Packard IT Service Management Reference Model (HP ITSMRM 2000)
- International Business Machines Systems Management Solutions Life Cycle, IBM Rational Software.
- Microsoft Operations Framework

This list represents only a sample of the existing service architecture frameworks.

One great example of architecture frameworks applications for service systems, the “High Level Reference Model for the Smart Grid,” developed by NIST in 2010 under the “Energy Independence and Security Act of 2007” (EISA), is presented below:

> *EISA designated the development of a Smart Grid as a national policy goal, specifying that an interoperability framework should be “flexible, uniform and technology neutral. The law also instructed that the framework should accommodate “traditional, centralized generation and distribution resources” while also facilitating incorporation of new, innovative Smart Grid technologies, such as distributed renewable energy resources and energy storage.* (NIST 2010)

The NIST reference model was developed as “a tool for identifying the standards and protocols needed to ensure interoperability and cyber security, and defining and developing architectures for systems and subsystems within the smart grid." Figure 1 illustrates this model and the strategic (organizational), informational (business operations, data structures, and information exchanges required among system entities), and technical needs of the smart grid (data structures, entities specifications, interoperability requirements, etc.).

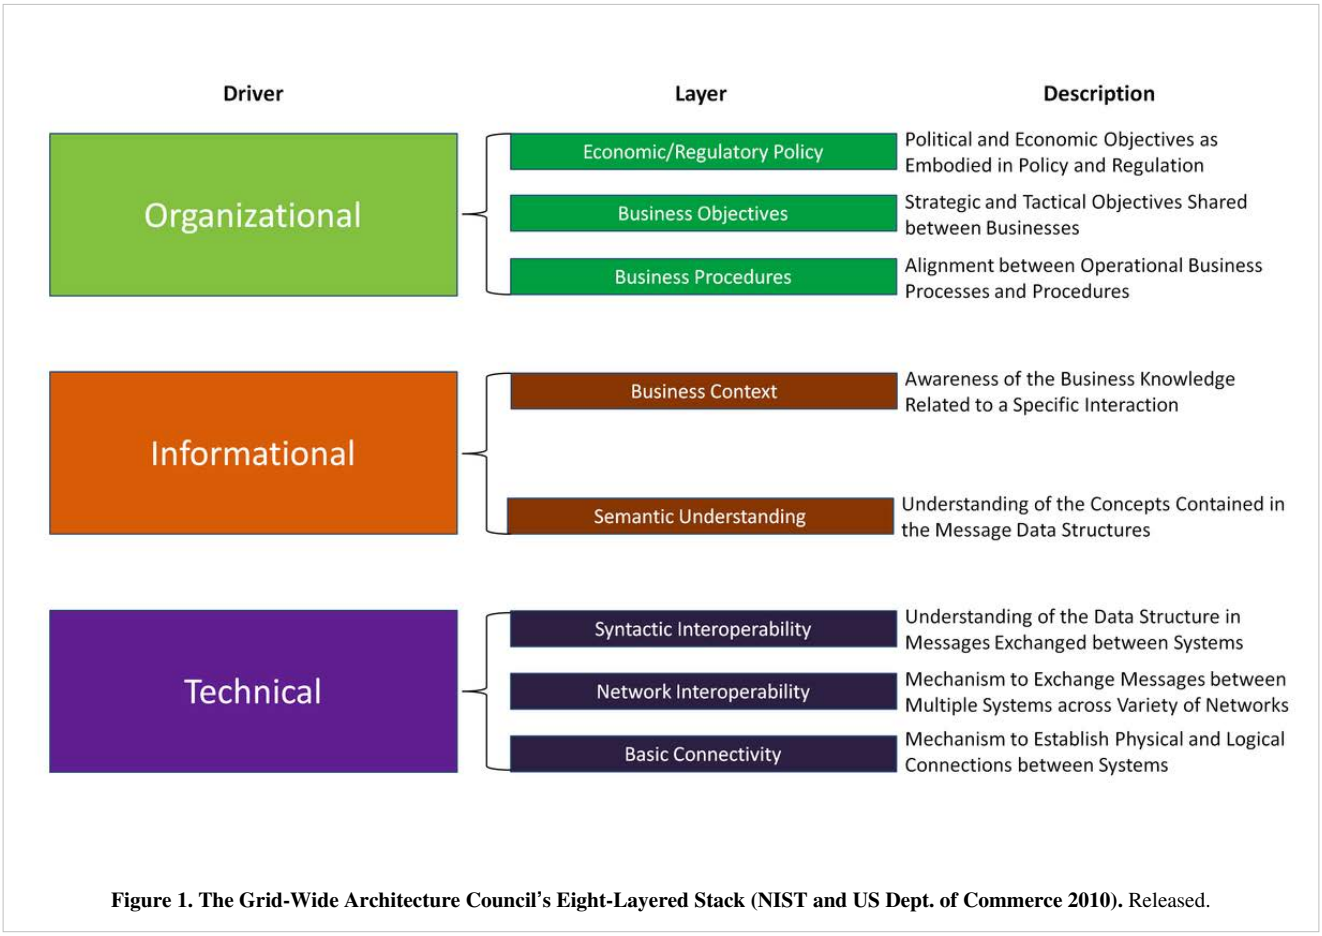

Figure 1. The Grid-Wide Architecture Council's Eight-Layered Stack (NIST and US Dept. of Commerce 2010). Released.

The NIST reference model uses this architecture framework to identify existing standards, identify new standards required for interoperability among interconnected networks, and to enable innovations where smart grid components (energy sources, bulk generation, storage, distribution, transmission, metering, cyber infrastructure, markets, service providers, customers, etc.) are supported by a broad range of interoperable options by well-defined interfaces useful across industries, including security. Emerging/innovative service development with massively scaled, well-managed, and secured networks will enable a dynamic market driven ecosystem representing new economic growth (NIST 2010).

This architecture framework is being used today by different standards organizations, such as the Smart Grid Interoperability Panel (SGIP), and several smart grid working groups. For details on priorities, working programs, and working group charters, see "High Level Reference Model for the Smart Grid" (NIST 2010).

For service systems, the application of any of these frameworks requires modifications/adaptations to create dynamic frameworks aware of environmental changes due to competitor's offerings, market demands, and customer co-creation. Most frameworks are static in nature; this requires business operations to manage changes through pre-defined (pre-programmed) processes for service configuration and change control. Dynamic frameworks would allow real-time, or near real-time, analysis of impacts of newly discovered service on business processes, organizations, and revenue for run-time environment deployment.

Automatic service configuration and change control are being incorporated into the management process via service oriented architecture (SOA) for service automation (Gu et al. 2010) and service oriented computing (Maglio et al. 2010). In particular, progress has been made over the last ten years on the standards for adaptation, orchestration and creation of web services (WS) for service based applications (SBA). A good summary of existing life cycle approaches for adaptable and evolvable SBA is presented in (Papazoglou et al. 2010). Some examples of this are

- web services development life cycle (SDLC);

- rational unified process (RUP) for SOA;
- service oriented modeling and architecture (SOMA); and
- service oriented analysis and design/decision Modeling (SOAD).

Further research is required to understand the architectural implications of dynamic service configuration, including research on human behavior, social aspects, governance processes, business processes, and implications of dynamic service level agreements (SLA) for an enterprise service system. New ways are needed to include adaptation requirements for new technologies that will exchange information with the service system entities and may have their own specifications. These technologies include robots, sensors, renewable energy, nanotechnologies, three dimensional printers, and implantable medical devices.

Service Systems Engineering Stages

- Lead Authors:
- Ricardo Pineda, Bud Lawson, and Richard Turner

-

This article describes the stages of the service systems development process (SSDP) and expected outputs for each stage; for a closer alignment with the traditional systems engineering (TSE) process, the concept and feasibility phases have been combined into a single service strategy/concept as discussed in the SEBoK Systems Engineering and Management article. All of the stages of the SSDP take a similar iterative approach to fully understand the enterprise capabilities, enterprise process impact, information technology (IT), and technology impacts and customer expectations. Lin and Hsieh (2011) provide a good summary on New service Development processes. The Information Technology Infrastructure Library (ITIL) stage names have been purposely added to the SSDP to show the needed alignment between IT and technology. The reader should keep in mind that even though IT is crucial to the overall end-to-end system, service technology development needs must be taken into consideration in all the stages of SSDP.

Service Strategy/Concept

A service strategy/concept is the entry into the SSDP. The concept may be generated by an end-user (enterprise customer or consumer), a business manager, an engineering organization, new web service designers, new technology developments, and/or information technology trends. The service concept is the highest level of the service idea and it usually addresses what service is being proposed to what markets and to whom within these markets.

A high-level feasibility assessment of the concept is then carried out by the integrated service development team (ISDT) to assess the needs/impacts on enterprise process capabilities, operational capabilities, and/or new technology developments (access, infrastructure, operations support systems (OSS), service support systems (SSS), and business support systems (BSS). It should also consider any impacts on service governance, social, cultural, and human behaviors. The feasibility assessment also gives a plus or minus 30% estimate on the time to develop and the cost of development, which are entry points into the business case to evaluate whether the service is viable to develop and to market given the constraints and estimates. At this time, a decision (decision gate) determines if the service is to be developed.

If the business case is viable, then a detailed business description of the service is developed. This includes functions and features to be included, phases of development, markets to be addressed, customers within the markets to be targeted, and customer experiences expected from the service (i.e., defining the non-functional requirements of the service, such as the quality of service (QoS), availability, reliability, and security considerations and offerings within the service). This description allows detailed studies of expected human-computer interactions, social networking, technology requirements, and operations requirements. Governance and organizational process requirements should also be included to generate the “service description” as the main output from this stage.

Service systems engineering (SSE) takes an important role in understanding and eliciting the enterprise service concepts. Clearly, understood end-to-end business processes required for the intended service are fundamental to its successful development, deployment, and customer satisfaction. SSE works with business process management (BPM), social science, and cognitive science to elicit intended service operations, including target audiences, pre-sale, sale, and post-sale customer care processes.

Requirements Analysis and Engineering

A service requirements document is created that describes the service functions, the service entities, the intended interaction among entities, and the customer-facing and internal-facing functions/processes that are required to support the service. This description should conceptually include intended service level agreements (SLAs) and the obligations of the service provider process should there be any degree of non-compliance during service operation.

In addition to the TSE activities described earlier, the SSE requirements analysis and engineering process must develop a customer-centric view of the service to analyze SLA, QoS, value co-creation, monitoring, and assessment requirements to comply with the expected/planned SLA. This analysis will determine whether dynamic changes of the service are required during service operation to correct faults, reconfigure, administer, or to adapt/self-adapt for possible performance degradations.

Beyond the traditional service life cycle management (LCM) processes, the requirements must also be developed for service level management (SLM) processes and systems. These are needed to monitor, measure, and assess key performance indicators (KPIs), technical performance measures (TPMs), and service performance measures (SPMs) according to the SLA.

The SSE requirements analysis addresses the support systems for the governance, business, service, operations, and support processes to derive requirements for technologies, information systems, processes, and enterprise organizations. Interface requirements, information flows, and data requirements are also within the scope of requirements analysis. The main output is the service requirements document (SRD).

SSE plays a critical role in describing the services needs for day-to-day operations. These include customer care centers requirements and interfaces between network infrastructure provider(s), content provider(s), service provider(s), service based application provider(s), and the customer management process for the service. All of these are described in detail in the service operations plans (SOPs) and the operations technical plans (OTPs).

Systems Design/Development

The SRD, SOP, and OTP have enough detail regarding the service functions, operations, interfaces, and information flows required among the different service system entities to analyze, identify, and recommend end-to-end applicable architecture frameworks; to carry out trade-off analyses for the alternatives among service system entities; and to describe and allocate relationships (interactions) among entities at all levels of the service architecture. Detailed requirements are worked at lower levels to generate specifications for entity developers including data structures, data flow diagrams, and allocated performance requirements.

ITIL v. 3 (OGC 2007) recommends inclusion of the following service design processes:

- service catalog management,
- service level management,
- capacity management,
- availability management,
- service continuity management,
- security management, and
- supplier/provider management.

Service Integration, Verification & Validation

SSE defines integration and interface requirements for the seamless operation of the service. In this regard, the system engineer takes an integrator role to ensure proper data generation and flow through all the different systems composing the service offered. The goal is to ensure customers (consumer or internal) are getting the information required to carry out the tasks required in the business, operations, service, and customer processes. The service integration, verification, and validation plans need to include end-to-end verification and validation procedures for any new development or adaptations required for planned dynamic configuration/re-configuration of previously tested service systems. (See also System Verification and System Validation.)

The systems engineer creates these plans using a number of different perspectives. These include:

- end-to-end service (service validation test plans),
- customer care (operational readiness test plans),
- service provider (network validation test plans),
- service system entities interoperability/interface test plans,
- content provider (content validation test plans), and
- application (user acceptance test plans).

Service Transition/Deployment

Service systems may change very rapidly and new enhancements, new features, or new applications can be added as incremental developments, new developments, or adaptation to service offerings. Service systems engineers review new requirements to assess the feasibility of the changes to the service system entities, technologies, processes, and organizations, as well as their impacts on the service offerings. The service transition/deployment stage takes input from service development to plan for service insertion, technology insertion, processes adaptations, and implementation with minimal impact to existing services. During this stage, special care is taken with integration, verification, and validation test plans and regression testing to ensure new developments work flawlessly with existing services.

ITIL v. 3 (OGC 2007) recommends the following processes in the transition/deployment stage:

- transition planning and support,
- change management,
- service asset and configuration management,
- release and deployment management,
- service validation and testing,
- evaluation, and
- knowledge management.

Service Operations/Continuous Service Improvement (CSI)

Service operation manages the day-to-day activities of all aspects of the end-to-end service delivery to the customer. It manages the operations, administration, maintenance, and provisioning of the service, technology, and infrastructure required to deliver the contracted service to the customer within the specified service levels. The main service operations processes in ITIL v. 3 are

- event management,
- incident management,
- problem management,
- request fulfillment, and
- access management.

A continuous service improvement (CSI) plan for the implementation of technologies and tools for the continuous improvement of the service, monitoring, measuring, and analyzing process and service metrics is essential.

Service Systems Engineering Tools & Technologies

Tools and technologies from a broad spectrum of fields are extensively used during the different stages of SSE. Not only are they used for the development of the hardware, software, information systems and technology components, but also for the modelling, definition, and design of the organization, processes, and data structures of the service system (See also Representing Systems with Models). These tools and technologies include modelling, simulation, development, test bed, and social environmental aspects of the intended or to be designed service. The tools fall into three main domains:

1. business process management (BPM),
2. service design process, and
3. service design management.

Business process management (BPM) generally deals with process management scenarios to coordinate people and systems, including sequential workflow, straight through processing, case management, content life cycle management, collaborative process work, and value chain participation. Systems engineers work with service managers to align the business architectures with the technology and IT architecture. The business process modeling notation (BPMN) is a graphic notation standard that is implemented to describe a process's realization within any given workflow. This notation is linked with web services business process execution language (WS-BPEL), a format used to perform an automated business process by implementing web services technology. For an extensive review of existing BPM tools and BPM suites, please see Hantry et al. (2010), Carroll et al. (2010), Andrikoupolous et al. (2010), Lin and Hsieh (2011), and Ward-Dutton (2010).

Service design process: Architecture frameworks (AF) and enterprise architectures (EAs) are standards that help split complex systems (see also Complexity) into an interrelated, structured form. They describe the different characteristics of the products and services. Systems engineering modeling tools, such as the unified modeling language (UML) (OMG 2010a) and system modeling language (SysML) (OMG 2010b), help develop the AF and EA and greatly impact the continued evolution and successful implementation of complex projects. Service oriented architecture (SOA) and systems and software engineering architecture (ISO/IEC/IEEE 2011) are standards that apply architecture principles for specialized applications. Successful implementation of the architecture tools helps identify critical interfaces and improves understanding of the allocations between components and functions.

Model-based systems engineering (MBSE), model driven architectures (MDA), and model oriented systems engineering (MOSES) are examples of commonly used tools for logical (functional), behavioral (operational), and physical design of the IT. UML, UML 2.0, and SysML are extensively used to describe operational scenarios, modes of operations, use cases, and entity relationships. For an extensive review of MBSE, MDA, and MOSES, please see Friedenthal (1998), Estefan (2008), Pezuela (2005), Andrikopoulos et al. (2010), and Hybertson (2010).

In addition, trade-off and engineering analyses use different optimization methodologies. Since services exhibit a significant level of randomness, statistical analysis, demand forecasting, multi-objective optimization, queuing theory, and stochastic optimization methodologies are tools used to model and simulate the service system behavior. These methodologies support decision making in areas as diverse as resource allocation, number of facilities, facilities' geographical locations, fleet routing and optimization, service systems reliability and prognosis, and network optimization. A good overview of these methodologies can be found in Daskin (2010).

During the service design process (SDP), planning for the implementation of technologies and tools for the continuous improvement of the service is performed. These tools support monitoring, measuring, and analyzing process and service performance metrics. The Deming cycle (plan, do, check, and act (PDCA) is widely used as the foundation for quality improvements across the service. Lean manufacturing, six sigma, swim lanes, balanced scoreboard, benchmarking, and gap analysis methodologies are commonly used for service evaluation and

continuous improvement.

Service design management: There are standards for implementing and managing systems engineering processes (IEEE 1220 (1998)) that help coordinate and synchronize all the service systems engineering processes leading to improved organizational collaboration and improved service delivery (see also Systems Engineering Standards). Standards have been developed in software engineering for product evaluation (ISO/IEC 14598 (1998)) and product quality (ISO/IEC 9126 series (2003a, 2003b, & 2004)), as well as information security management (ISO 27001 (2005)) and evaluation series (ISO 15408 (2008a, 2008b, & 2009)). The ITIL v. 3 describes best practices for IT service management, which can be extended to include service systems.

-

Enterprise systems engineering (ESE) is the application of systems engineering principles, concepts, and methods to the planning, design, improvement, and operation of an enterprise.

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs in turn are divided into topics. This KA contains the following topics:

- Enterprise Systems Engineering Background
- The Enterprise as a System
- Related Business Activities
- Enterprise Systems Engineering Key Concepts
- Enterprise Systems Engineering Process Activities
- Enterprise Capability Management

Introduction

This knowledge area provides an introduction to systems engineering (SE) at the enterprise level in contrast to "traditional" SE (TSE) (sometimes called "conventional" or "classical" SE) performed in a development project or to "product" engineering (often called product development in the SE literature).

The concept of enterprise was instrumental in the great expansion of world trade in the 17th century (see note 1) and again during the Industrial Revolution of the 18th and 19th centuries. The world may be at the cusp of another global revolution enabled by the information age and the technologies and cultures of the Internet (see note 2). The discipline of SE now has the unique opportunity of providing the tools and methods for the next round of enterprise transformations.

> *Note 1. "The Dutch East India Company… was a chartered company established in 1602, when the States-General of the Netherlands granted it a 21-year monopoly to carry out colonial activities in Asia. It was the first multinational corporation in the world and the first company to issue stock. It was also arguably the* ***world's first mega-corporation****, possessing quasi-governmental powers, including the ability to wage war,*

negotiate treaties, coin money, and establish colonies." (emphasis added, National Library of the Netherlands 2010)

Note 2. This new revolution is being enabled by cheap and easily usable technology, global availability of information and knowledge, and increased mobility and adaptability of human capital. The enterprise level of analysis is only feasible now because organizations can work together to form enterprises in a much more fluid manner.

ESE is an emerging discipline that focuses on frameworks, tools, and problem-solving approaches for dealing with the inherent complexities of the enterprise. Furthermore, ESE addresses more than just solving problems; it also deals with the exploitation of opportunities for better ways to achieve the enterprise goals. A good overall description of ESE is provided by in the book by Rebovich and White (2011).

Key Terms

Enterprise

An enterprise consists of a purposeful combination (e.g., a network) of interdependent resources (e.g., people, processes, organizations, supporting technologies, and funding) that interact with

- each other to coordinate functions, share information, allocate funding, create workflows, and make decisions, etc.; and
- their environment(s) to achieve business and operational goals through a complex web of interactions distributed across geography and time (Rebovich and White 2011, 4-35).

The term enterprise has been defined as follows:

(1) *One or more organizations sharing a definite mission, goals, and objectives to offer an output such as a product or service.* (ISO 2000);

(2) *An organization (or cross organizational entity) supporting a defined business scope and mission that includes interdependent resources (people, organizations and technologies) that must coordinate their functions and share information in support of a common mission (or set of related missions).* (CIO Council 1999);

(3) *The term enterprise can be defined in one of two ways. The first is when the entity being considered is tightly bounded and directed by a single executive function. The second is when organizational boundaries are less well defined and where there may be multiple owners in terms of direction of the resources being employed. The common factor is that both entities exist to achieve specified outcomes.* (MOD 2004); and

(4) *A complex, (adaptive) socio-technical system that comprises interdependent resources of people, processes, information, and technology that must interact with each other and their environment in support of a common mission.* (Giachetti 2010)

An enterprise must do two things: (1) develop things within the enterprise to serve as either external offerings or as internal mechanisms to enable achievement of enterprise operations, and (2) transform the enterprise itself so that it can most effectively and efficiently perform its operations and survive in its competitive and constrained environment.

Enterprise vs Organization

It is worth noting that an enterprise is not equivalent to an "organization" according to the definition above. This is a frequent misuse of the term enterprise. The figure below shows that an enterprise includes not only the organizations that participate in it, but also people, knowledge, and other assets such as processes, principles, policies, practices, doctrine, theories, beliefs, facilities, land, intellectual property, and so on.

Some enterprises are organizations, but not all enterprises are organizations. Likewise, not all organizations are enterprises. Some enterprises have no readily identifiable "organizations" in them. Some enterprises are self-organizing (i.e., not organized by mandate) in that the sentient beings in the enterprise will find for themselves some way in which they can interact to produce greater results than can be done by the individuals alone. Self-organizing enterprises are often more flexible and agile than if they were organized from above (Dyer and Ericksen 2009; Stacey 2006).

> *One type of enterprise architecture that supports agility is a non-hierarchical organization without a single point of control. Individuals function autonomously, constantly interacting with each other to define the vision and aims, maintain a common understanding of requirements and monitor the work that needs to be done. Roles and responsibilities are not predetermined but rather emerge from individuals' self-organizing activities and are constantly in flux. Similarly, projects are generated everywhere in the enterprise, sometimes even from outside affiliates. Key decisions are made collaboratively, on the spot, and on the fly. Because of this, knowledge, power, and intelligence are spread through the enterprise, making it uniquely capable of quickly recovering and adapting to the loss of any key enterprise component.* (http://en.wikipedia.org/wiki/Business_agility)

In spite of this lack of "organization" in some enterprises, SE can still contribute much in the engineering of the enterprise, as described in the articles below. However, SE must be prepared to apply some non-traditional approaches in doing so. Hence the need for embracing the new discipline called enterprise systems engineering (ESE).

Giachetti (2010) distinguishes between enterprise and organization by saying that an organization is a view of the enterprise. The organization view defines the structure and relationships of the organizational units, people, and other actors in an enterprise. Using this definition, we would say that all enterprises have some type of organization, whether formal, informal, hierarchical or self-organizing network.

Extended Enterprise

Sometimes it is prudent to consider a broader scope than merely the "boundaries" of the organizations involved in an enterprise. In some cases, it is necessary (and wise) to consider the "extended enterprise" in modeling, assessment, and decision making. This could include upstream suppliers, downstream consumers, and end user organizations, and perhaps even "sidestream" partners and key stakeholders. The extended enterprise can be defined as:

> *Wider organization representing all associated entities - customers, employees, suppliers, distributors, etc. - who directly or indirectly, formally or informally, collaborate in the design, development, production, and delivery of a product (or service) to the end user.* (http://www.businessdictionary.com)

Enterprise Systems Engineering

Enterprise systems engineering (ESE), for the purpose of this article, is defined as the application of SE principles, concepts, and methods to the planning, design, improvement, and operation of an enterprise (see note 3). To enable more efficient and effective enterprise transformation, the enterprise needs to be looked at "as a system," rather than merely as a collection of functions connected solely by information systems and shared facilities (Rouse 2009). While a systems perspective is required for dealing with the enterprise, this is rarely the task or responsibility of

people who call themselves systems engineers.

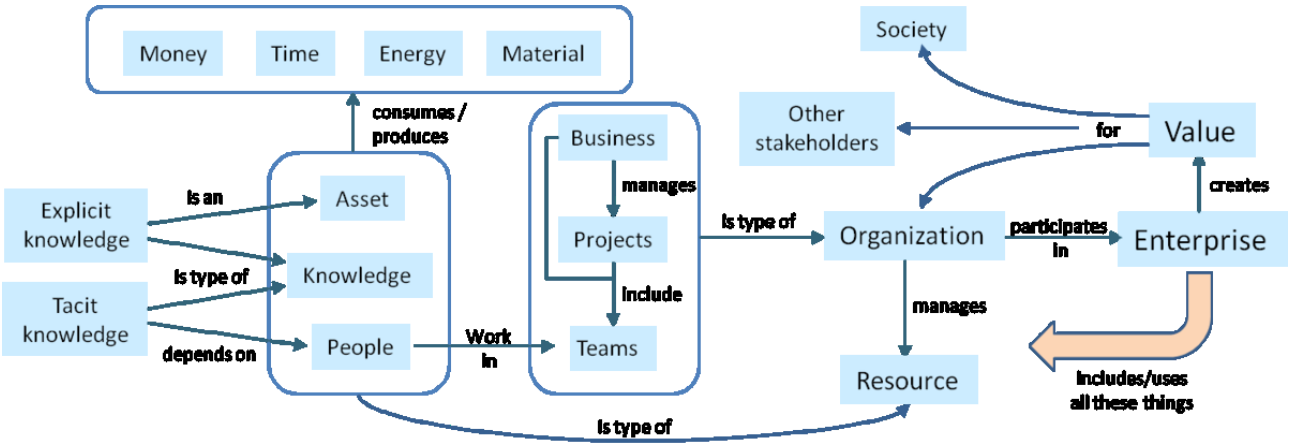
> *Note 3. This form of systems engineering (i.e., ESE) includes (1) those traditional principles, concepts, and methods that work well in an enterprise environment, plus (2) an evolving set of newer ideas, precepts, and initiatives derived from complexity theory and the behavior of complex systems (such as those observed in nature and human languages).*

Creating Value

The primary purpose of an enterprise is to create value for society, other stakeholders, and for the organizations that participate in that enterprise. This is illustrated in Figure 1 that shows all the key elements that contribute to this value creation process.

There are three types of organizations of interest: businesses, projects, and teams (see note 4). A typical business participates in multiple enterprises through its portfolio of projects. Large SE projects can be enterprises in their own right, with participation by many different businesses, and may be organized as a number of sub-projects.

> *Note 4. The use of the word "business" is not intended to mean only for-profit commercial ventures. As used here, it also includes government agencies and not-for-profit organizations, as well as commercial ventures. Business is the activity of providing goods and services involving financial, commercial, and industrial aspects.*



Notes:

1. **All entities shown are decomposable, except people. For example, a business can have sub-businesses, a project can have subprojects, a resource can have sub-resources, an enterprise can have sub-enterprises.**
2. **All entities have other names. For example, a program can be a project comprising several subprojects (often called merely projects). Business can be an agency, team can be group, value can be utility, etc.**
3. **There is no attempt to be prescriptive in the names chosen for this diagram. The main goal of this is to show how this chapter uses these terms and how they are related to each other in a conceptual manner.**

Figure 1. Organizations Manage Resources to Create Enterprise Value. (SEBoK Original)

Resource Optimization

A key choice for businesses that conduct SE is to what extent, if at all, they seek to optimize their use of resources (people, knowledge, assets) across teams, projects, and business units. Optimization of resources is not the goal in itself, but rather a means to achieve the goal of maximizing value for the enterprise and its stakeholders. At one extreme, in a product-oriented organization, projects may be responsible for hiring, training, and firing their own staff, as well as managing all assets required for their delivery of products or services. (The term "product-oriented organization" is not meant in the sense of product-oriented SE, but rather in the sense of this being one of the basic constructs available when formulating organizational strategy.)

At the other extreme, in a functional organization, the projects delegate almost all their work to functional groups. In between these two extremes is a matrix organization that is used to give functional specialists a “home” between project assignments. A full discussion of organizational approaches and situations along with their applicability in enabling SE for the organization is provided in the article called Systems Engineering Organizational Strategy.

The optimization debate can be handled as described in the book called "Enterprise Architecture as Strategy" (Ross, Weill, and Robertson 2006). In other words, an enterprise can choose (or not) to unify its operations and can choose (or not) to unify its information base. There are different strategies the enterprise might adopt to achieve and sustain value creation (and how ESE helps an enterprise to choose). This is further addressed in the section on Enterprise Architecture Formulation & Assessment in the article called Enterprise Capability Management.

Enabling Systems Engineering in the Organization

SE skills, techniques, and resources are relevant to many enterprise functions, and a well-founded SE capability can make a substantial contribution at the enterprise level, as well as at the project level. The article called Systems Engineering Organizational Strategy discusses enabling SE in the organization, while the article called Enabling Businesses and Enterprises focuses on the cross-organizational functions at the business and enterprise levels. The competence of individuals is discussed in the article called Enabling Individuals.

Kinds of Knowledge Used by the Enterprise

Knowledge is a key resource for ESE. There are generally two kinds of knowledge: explicit and tacit. Explicit knowledge can be written down or incorporated in computer codes. Much of the relevant knowledge, however, is “tacit knowledge” that only exists within the heads of people and in the context of relationships that people form with each other (e.g., team, project, and business level knowledge). The ability of an organization to create value is critically dependent on the people it employs, on what they know, how they work together, and how well they are organized and motivated to contribute to the organization’s purpose.

Projects, Programs & Businesses

The term “program” is used in various ways in different domains. In some domains a team can be called a program (e.g., a customer support team is their customer relationship "program"). In others, an entire business is called a program (e.g., a wireless communications business unit program), and in others the whole enterprise is called a program (e.g., the Joint Strike Fighter program and the Apollo Space program). And in many cases, the terms project and program are used interchangeably with no discernible distinction in their meaning or scope. Typically, but not always, there are program managers who have profit and loss (P&L) responsibility and are the ultimate program decision makers. A program manager may have a portfolio of items (services, products, facilities, intellectual property, etc.) that are usually provided, implemented, or acquired through projects.

The Office of Government Commerce provides a useful distinction between programs and projects:

> *The ultimate goal of a Programme is to realise outcomes and benefits of strategic relevance. To achieve this a programme is designed as a temporary flexible organisation structure created to coordinate, direct and oversee the implementation of a set of related projects and activities in order to deliver outcomes and benefits related to the organisation’s strategic objectives...*
>
> *A programme is likely to have a life that spans several years. A Project is usually of shorter duration (a few months perhaps) and will be focussed on the creation of a set of deliverables within agreed cost, time and quality parameters.* (OGC 2010)

Practical Considerations

When it comes to performing SE at the enterprise level, there are several good practices to keep in mind (Rebovich and White 2011):

- Set enterprise fitness as the key measure of system success. Leverage game theory and ecology, along with the practices of satisfying and governing the commons.
- Deal with uncertainty and conflict in the enterprise through adaptation: variety, selection, exploration, and experimentation.
- Leverage the practice of layered architectures with loose couplers and the theory of order and chaos in networks.

Enterprise governance involves shaping the political, operational, economic, and technical (POET) landscape. One should not try to control the enterprise like one would in a TSE effort at the project level.

- Alan Faisandier

-

This article provides a common context for the succeeding topics in the knowledge area.

Capabilities in the Enterprise

The enterprise acquires or develops systems or individual elements of a system. The enterprise can also create, supply, use, and operate systems or system elements. Since there could possibly be several organizations involved in this enterprise venture, each organization could be responsible for particular systems or perhaps for certain kinds of elements. Each organization brings their own organizational capability with them and the unique combination of these organizations leads to the overall operational capability of the whole enterprise. These concepts are illustrated below.

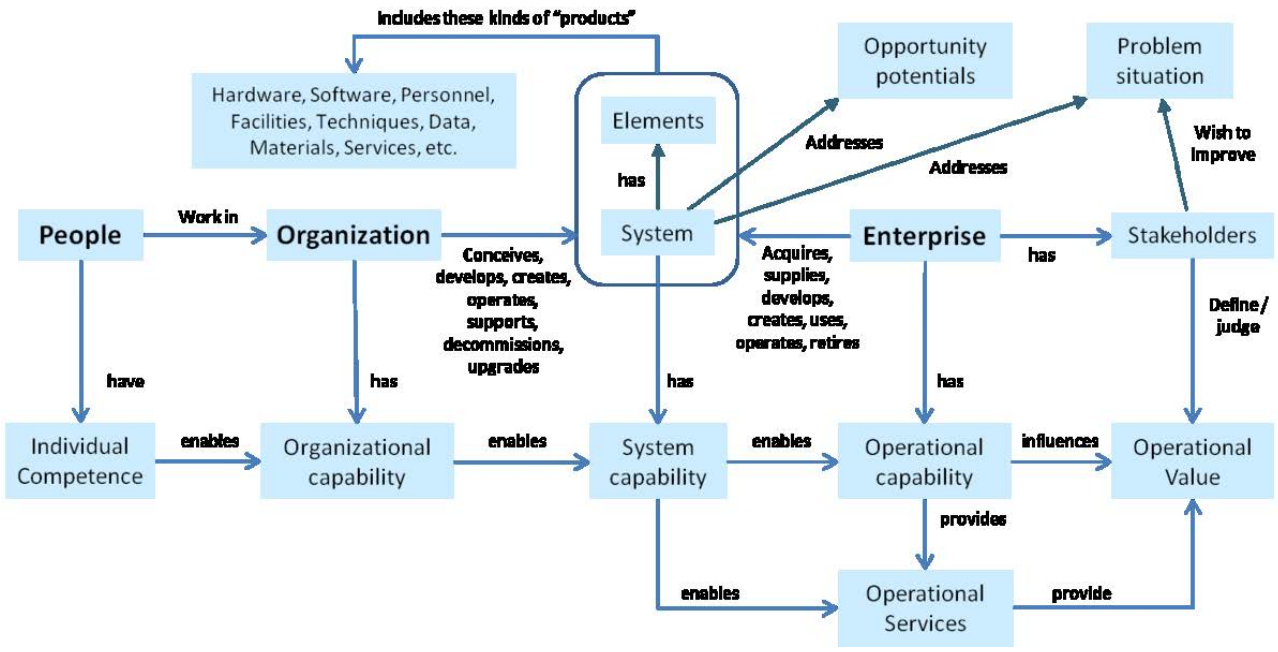

Figure 1. Individual Competence Leads to Organizational, System & Operational Capability. (SEBoK Original)

Organizational capabilities are addressed in the article on Systems Engineering Organizational Strategy, and individual competencies are addressed in the article on Enabling Individuals as they relate to the principles, theories, and practices of organizational behavior.

Organizational Capabilities and Competencies

The word "capability" is used in systems engineering (SE) in the sense of "the ability to do something useful under a particular set of conditions." This article discusses three different kinds of capabilities: organizational capability, system capability, and operational capability. It uses the word "competence" to refer to the ability of people relative to the SE task. Individual competence, (sometimes called "competency"), contributes to, but is not the sole determinant of, organizational capability. This competence is translated to organizational capabilities through the

work practices that are adopted by the organizations. New systems (with new or enhanced system capabilities) are developed to enhance enterprise operational capability in response to stakeholder's concerns about a problem situation.

Enterprise stakeholders are the ultimate arbiters of value for the system to be delivered. Organizational, system, and operational capabilities cannot be designed, improved, and implemented independently. The key to understanding the dependencies between capabilities is through architecture modeling and analysis as part of the activities described in the article called Enterprise Capability Management. "Capability engineering" is an emerging discipline that could enhance the effectiveness of enterprise systems engineering (ESE), which is further discussed in the article on Systems of Systems (SoS).

Organizational Design

The competencies of individuals are important to the overall organizational capability as discussed in the article on Enabling Individuals. The organizational capability is also a function of how the people, teams, projects, and businesses are organized. The organizational design should specify the roles, authorities, responsibilities, and accountabilities (RARA) of the organizational units to ensure the most efficient and effective operations. Effectiveness of enterprise operations is certainly driven by management principles, concepts, and approaches, but it is also largely driven by its leadership principles, concepts, and approaches. These factors are discussed in the article on Systems Engineering Organizational Strategy that discusses how to organize for effective performance of SE.

Organizational structure is tightly tied to creating value for the enterprise's various stakeholders. Since the enterprise is made up of various elements including people, processes, technologies, and assets, the organizational structure of the people and the allocation of responsibilities for executing portions of the value stream is a "design decision" for the enterprise and hence is a key element of properly performing ESE. Organizational design is increasingly influenced by the portfolio of products and services and the degree of coupling between them. This organizational design will be based on organizational design patterns and their tradeoffs, as discussed in the article on Systems Engineering Organizational Strategy. Browning (2009) discusses one approach for modeling and analysis of an organization.

Operational Capabilities & Operational Services

As you can see in this figure, operational capabilities provide operational services that are enabled by system capabilities. These system capabilities are inherent in the system that is conceived, developed, created and/or operated by an enterprise. ESE concentrates its efforts on maximizing operational value for various stakeholders, some of whom may be interested in the improvement of some problem situation.

ESE, however, addresses more than just solving problems; it also deals with the exploitation of opportunities for better ways to achieve the enterprise goals. This opportunity might involve lowering of operating costs, increasing market share, decreasing deployment risk, reducing time to market, and any number of other enterprise goals. The importance of addressing opportunity potentials should not be underestimated in the execution of ESE practices.

This article focuses on the *operational capabilities* of an enterprise and the contribution of these capabilities to *operational value* (as perceived by the stakeholders). Notice that the organization or enterprise can deal with either the system as a whole or with only one (or a few) of its elements. These elements are not necessarily hard items, like hardware and software, but can also include "soft" items, like people, processes, principles, policies, practices, organizations, doctrine, theories, beliefs, and so on.

Services vs. Products vs. Enterprises

A service system is a collection of items (or entities) that perform the operations, administration, management and provisioning (OAM&P) of resources that together provide the opportunities to co-create value by both the service provider and the service consumer.

A collection of services is not necessarily a service system. In fact, this collection of services is often merely a product system that is one of the resources being OAM&P'ed by the service system. A product system can be composed of hardware, software, personnel (see note 1), facilities, data, materials, techniques, and even services. Each of these product system elements can be "engineered."

> *Note 1. Even personnel are engineered in the sense that their roles and responsibilities are specified precisely and trade-offs are made about which functions are performed by these people versus by hardware or software. People are "produced" in the sense that untrained people are trained to perform their allocated system functions, unknowledgeable people are educated to find or create the information they need to do their assigned task, and uninformed people are taught how to get access to the data they need, and how to extract relevant information from that data.*

It is important to understand the difference between the services "enabled" by a service system versus the services that are the elements of a service system entity. See the Service Systems Engineering article for more information about services and how they are engineered.

Likewise, a collection of services is not necessarily an enterprise system. An enterprise may be composed of service systems, along with product systems, as well as policies, procedures, properties, knowledge, financial capital, intellectual capital, and so on. An enterprise might even contain sub-enterprises. Enterprise SE must do the engineering not only across the enterprise itself, but may also get involved in the engineering of the service systems and products systems that the enterprise depends on in order to achieve its goals.

Enterprise Components

The above depictions of enterprise-related things do not show the components of an enterprise. The components of an enterprise when it is viewed as a “system” are different than the components of a product or service system (which is the focus of most literature on systems engineering). The figure below shows the typical kinds of components (shown here as “domains”) in an enterprise (Troux 2010) that could be utilized in achieving the desired enterprise *operational capability* as shown in Figure 1. It is this operational capability that drives ultimate value for the enterprise’s customers and other stakeholders. Further discussion on enterprise components is provided by Reese (2010) and Lawson (2010, chap. 8).

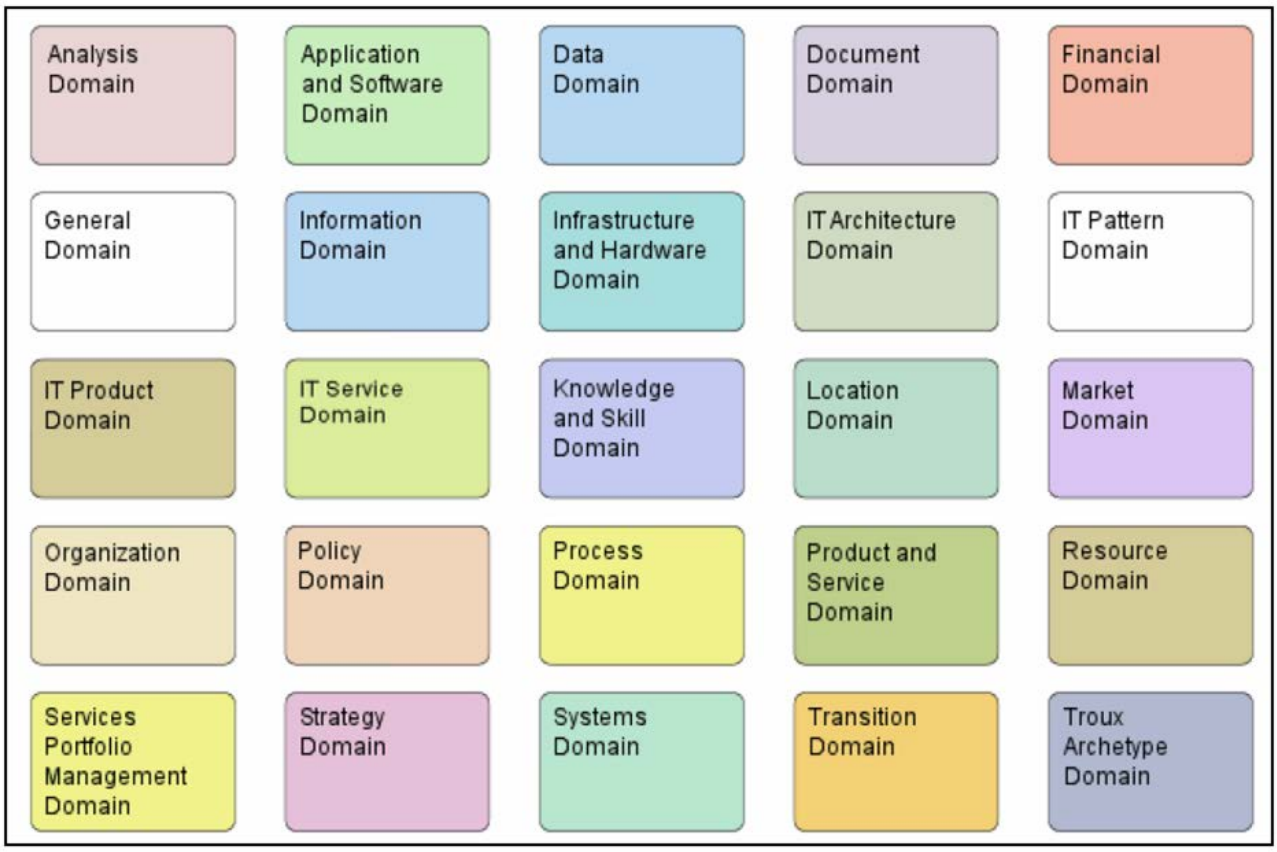

Figure 2. Categories of Enterprise Components (Troux Technologies, 2010). Reprinted with permission of Copyright © 2010 Troux Technologies. All other rights are reserved by the copyright owner.

The application/software and infrastructure/hardware domains (shown above) are likely the most familiar to systems engineers. The application/software domain contains things like the deployed software itself plus applications, modules, servers, patches, functions, and messages. The infrastructure/hardware domain contains things like the hardware itself plus networks and different kinds of hardware like computing hardware, cabinets, and network devices. There might different subtypes of computing hardware like computers, servers, desktops, laptops, and mainframes.

This particular "semantic model" had its origins in the area of information technology (IT) management but has been successfully expanded beyond the IT domain (Martin 2003 and 2005). You can see from this elaboration of these domains that an enterprise architecture "schema" can be quite extensive in the kinds of things it can model. The less technical domains would be things like policy, market, strategy, transition, financial, knowledge and skill, and analysis. In a typical enterprise architecture schema like this there could be over a hundred types of modeling objects grouped into these domains.

Various tools used in modeling the enterprise are described at http://www.enterprise-architecture.info/EA_Tools.htm (IEAD 2011). The TOGAF metamodel (http://pubs.opengroup.org/architecture/togaf9-doc/arch/chap34.html) used in The Open Group Architecture Framework (TOGAF) is another useful depiction of the various modeling entities involved in modeling the enterprise (TOGAF 2009).

Scope of Enterprise SE

Computer and communications technologies make it easier to integrate activities across the enterprise, but this does not necessarily make the enterprise more effective and efficient. To enable this to happen, one needs to look at the whole enterprise as a system, rather than as a collection of functions connected solely by information systems and shared facilities.

Essential Challenges

Enterprises face strategic challenges that are essential to address in order to ensure that the enterprise will succeed (Rouse 2009):

- **Growth:** Increasing impact, perhaps in saturated/declining "markets",
- **Value:** Enhancing relationships of processes to benefits and costs,
- **Focus:** Pursuing opportunities and avoiding diversions,
- **Change:** Competing creatively while maintaining continuity,
- **Future:** Investing in inherently unpredictable outcomes,
- **Knowledge:** Transforming information to insights to programs, and
- **Time:** Carefully allocating the organization's scarcest resource.

To address these challenges, one recognizes that the central source of value in the enterprise is in its people. "Understanding and supporting the interests of an enterprise's diverse stakeholders — and finding the 'sweet spot' among the many competing interests — is a central aspect of discerning the work of the enterprise as a system and creating mechanisms to enhance this work" (Rouse 2009).

Enterprise Transformation

Enterprises are constantly transforming, whether at the individual level (wherein individuals alter their work practices) or at the enterprise level (large-scale planned strategic changes) (Srinivasan 2010). These changes are a response on the part of the enterprise to evolving opportunities and emerging threats. It is not merely a matter of doing work better, but doing different work, which is often a more important result. Value is created through the execution of business processes. However, not all processes necessarily contribute to overall value (Rouse 2005, 138-150). It is important to focus on process and how they contribute to the overall value stream.

After gaining a good understanding of business processes, the next main concern is how best to deploy and manage the enterprise's human, financial, and physical assets. The key challenge in transforming an enterprise is, in the midst of all this change, continuing to *satisfice* key stakeholders (see note 2).

> *Note 2. "Satisfice" means to decide on and pursue a course of action satisfying the minimum requirements to achieve a goal. For the enterprise as a whole, it is often impossible to completely satisfy all stakeholders given their competing and conflicting concerns and interests. Therefore, the concept of "satisficing" is a very important element in the execution of ESE practices. It has less stringent criteria than the concept of "satisfaction," which is commonly used in product/service systems engineering.*

Systems engineers have to respond to an increased recognition of the 'connectedness' of products and systems, brought about by a number of trends, for example: the capability of (mainly digital) technology, working across multiple systems, to transform businesses and operational systems; the need to create systems in families to increase product diversity and reuse technology, in order to reduce development and operating costs; and the need to build systems which can be brought together flexibly in operations, even if such co-operation was not foreseen at the time of development.

There has also been an increase in collaborative systems development activities, often spanning national boundaries. This has proceeded alongside a growth in the development of what might be called *meta-systems,* that is systems comprising parts which would previously have been considered as complex in their own right a generation ago, now

conceived of and developed as a whole, and thus requiring fresh approaches, of the adaption of old ones.

Tackling these issues requires an approach that transcends the technical and process domain. ESE needs to address integration at the organizational and value chain level.

Transformation Context

Enterprise transformation occurs in the external context of the economy and markets as shown in the figure below (Rouse 2009). The “market” for the enterprise can be thought of as the context in which the enterprise operates. Of course, in the public sector, the enterprise’s “market” is commonly known as its “constituency.”

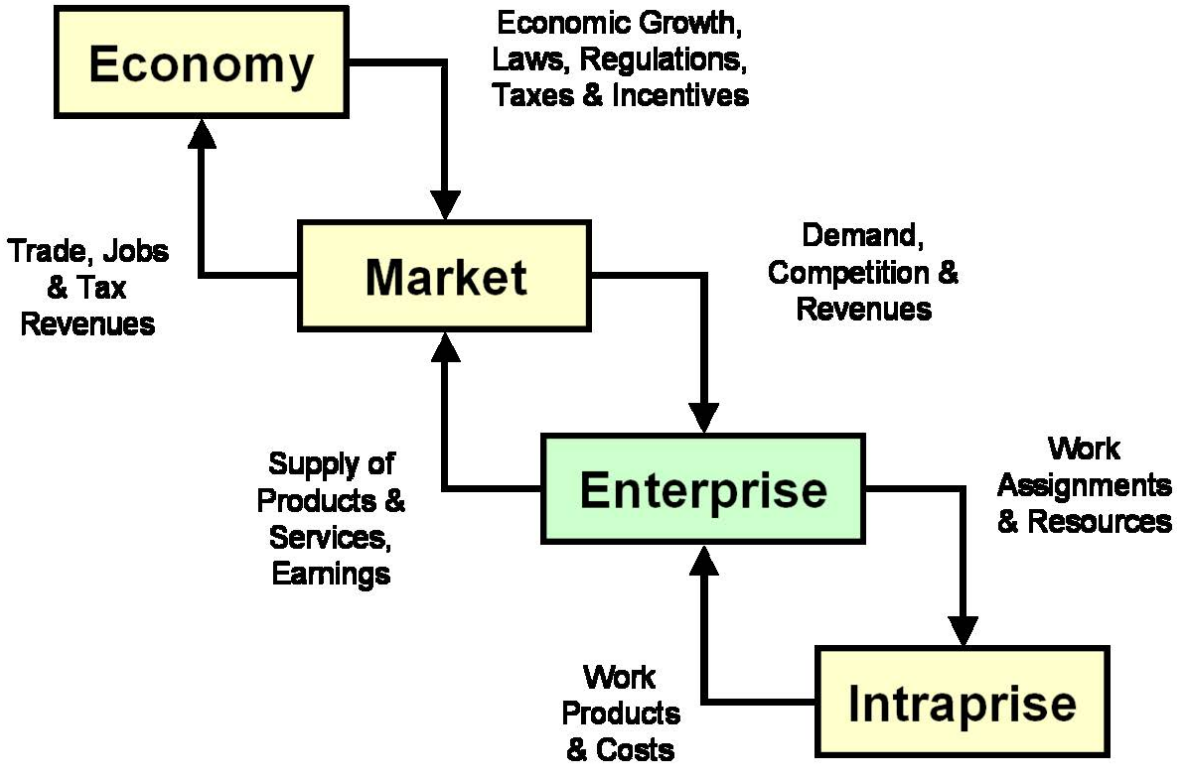

Figure 3. Context for Enterprise Transformation (Rouse 2009). Reprinted with permission of John Wiley & Sons Inc. All other rights are reserved by the copyright owner.

The term “intraprise” is used here to denote the many systems internal to the enterprise. This includes "information systems such as... ERP [enterprise resource planning] systems, as well as social and cultural systems. More specifically, work assignments are pursued via work processes and yield work products, incurring costs" (Rouse 2009). The social and cultural aspects of an enterprise are addressed further in the article called Enabling Businesses and Enterprises.

Modeling the Enterprise

Models of the enterprise can serve as the basis for understanding the enterprise in its context of markets and economies. The figure below shows the various drivers (or inputs) of an enterprise and its potential outcomes (or outputs) (Rouse 2009). Enterprise architecture can be a key enabler for modeling and can serve as a basis for transformation (Vernadat 1996; Bernus, Laszlo, and Schmidt 2003; Nightingale and Rhodes 2004). Enterprise architecture can be used to provide a model to understand how the parts of the enterprise fit together (or do not) (Giachetti 2010) (See also Representing Systems with Models). For a good review of the subject see Lillehagen and Krogstie (2008).

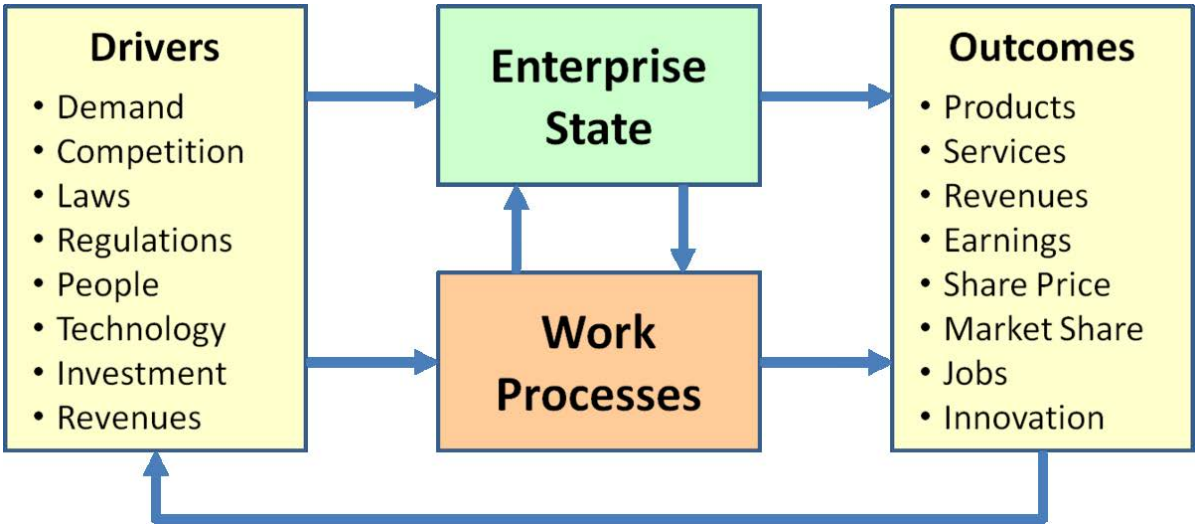

Figure 4. Drivers and Outcomes for the Enterprise (Rouse 2009). Reprinted with permission of John Wiley & Sons Inc. All other rights are reserved by the copyright owner.

In Pursuit of Value

Based on his theory of enterprise transformation, Rouse (2005, 279-295) has identified four alternative perspectives that tend to drive the need for transformation:

1. **Value Opportunities:** The lure of greater success via market and/or technology opportunities prompts transformation initiatives.
2. **Value Threats:** The danger of anticipated failure due to market and/or technology threats prompts transformation initiatives.
3. **Value Competition:** Other players' transformation initiatives prompt recognition that transformation is necessary to continued success.
4. **Value Crises:** Steadily declining market performance, cash flow problems, etc., prompt recognition that transformation is necessary for the enterprise to survive.

Work processes can be enhanced, streamlined, eliminated, and invented to help in the pursuit of enhanced value. These process changes should be aligned with enterprise strategy to maximize value produced by the enterprise (Hammer and Champy 1993). As shown below, there are many entities involved in helping the enterprise create value for society, participating organizations, and other stakeholders.

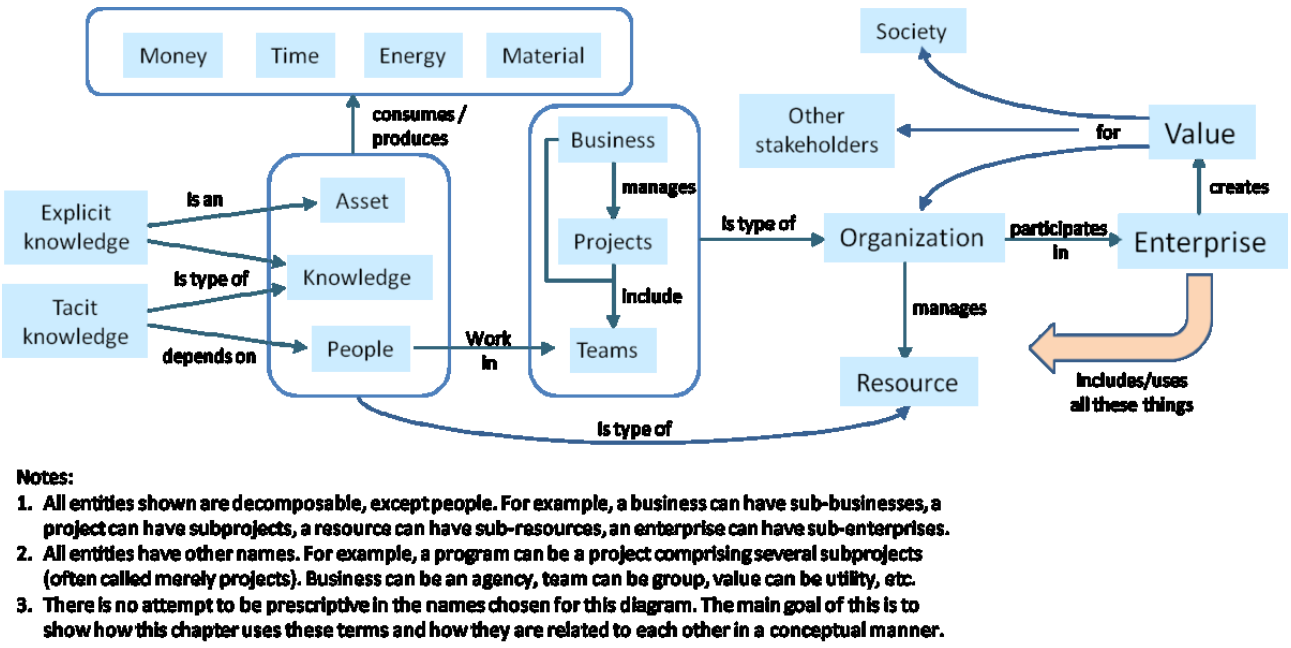

Figure 5. Organizations Manage Resources to Create Enterprise Value. (SEBoK Original)

The Enterprise as a System

- Lead Authors:
- James Martin, Bud Lawson, and Judith Dahmann

-

To enable more efficient and effective enterprise transformation, the enterprise needs to be looked at “as a system,” rather than as a collection of functions connected solely by information systems and shared facilities (Rouse 2005 and 2009; Lawson 2010). What distinguishes the design of enterprise systems from product systems is the inclusion of people as a component of the system, not merely as a user/operator of the system.

> *The term 'enterprise system' has taken on a narrow meaning of only the information system an organization uses. Research and project experience has taught us that to design a good enterprise system, we need to adopt a much broader understanding of enterprise systems. The greater view of enterprise systems is inclusive of the processes the system supports, the people who work in the system, and the information [and knowledge] content of the system.* (Giachetti 2010)

It is worth noting that the concept of "service" systems also includes people in the system. The thoughts above do not take this into account, primarily since their perspectives come mainly from a product system experience. The practice of service systems engineering is relatively new and is an emerging discipline. For more information on this, see the articles on Service Systems Engineering.

Creating Value

The primary purpose of an enterprise is to create value for society, other stakeholders, and for the organizations that participate in that enterprise. This is illustrated in Figure 1 that shows all the key elements that contribute to this value creation process. These elements in the enterprise can be treated as a "system" and the processes, methods, and tools ESE can be applied.

There are three types of organizations of interest: businesses, projects, and teams (see note 1). A typical business participates in multiple enterprises through its portfolio of projects. Large SE projects can be enterprises in their own right, with participation by many different businesses, and may be organized as a number of sub-projects.

> *Note 1. The use of the word “business” is not intended to mean only for-profit commercial ventures. As used here, it also includes government agencies and not-for-profit organizations, as well as commercial ventures. Business is the activity of providing goods and services involving financial, commercial, and industrial aspects.*

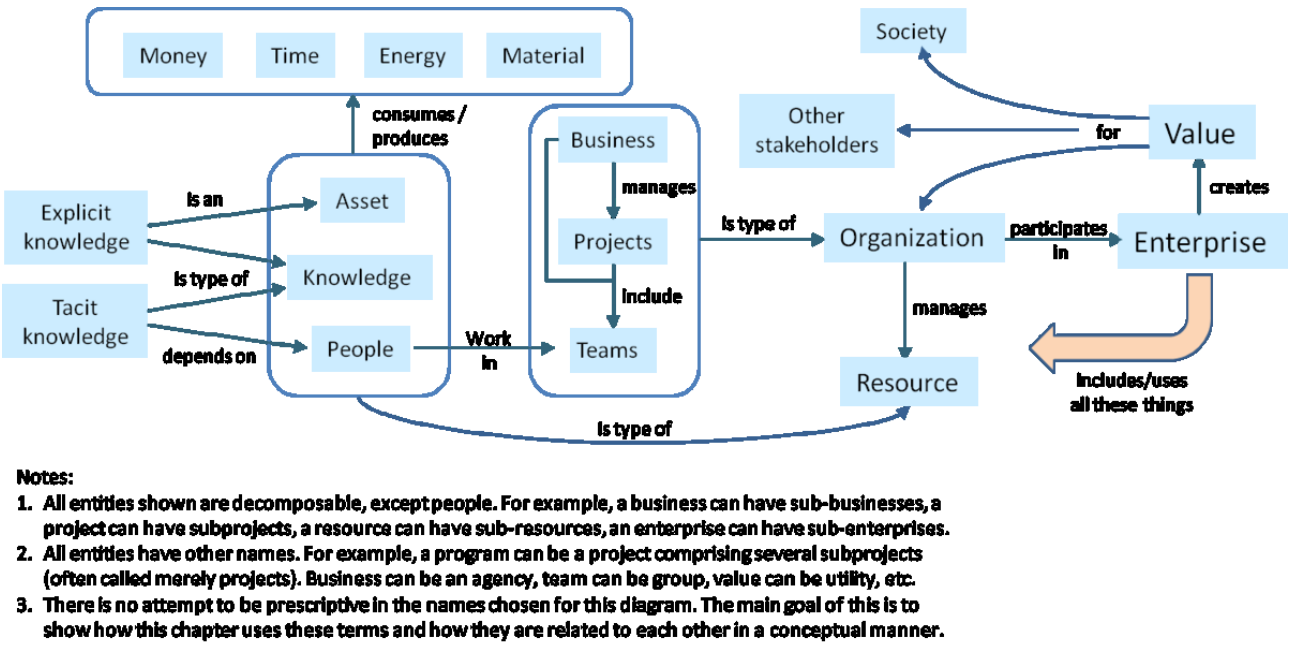

Figure 1. Organizations Manage Resources to Create Enterprise Value. (SEBoK Original)

Resource Optimization

A key choice for businesses that conduct SE is to what extent, if at all, they seek to optimize their use of resources (people, knowledge, assets) across teams, projects, and business units. Optimization of resources is not the goal in itself, but rather a means to achieve the goal of maximizing value for the enterprise and its stakeholders. At one extreme, in a product-oriented organization, projects may be responsible for hiring, training, and firing their own staff, as well as managing all assets required for their delivery of products or services. (The term "product-oriented organization" is not meant in the sense of product-oriented SE, but rather in the sense of this being one of the basic constructs available when formulating organizational strategy.)

At the other extreme, in a functional organization, the projects delegate almost all their work to functional groups. In between these two extremes is a matrix organization that is used to give functional specialists a “home” between project assignments. A full discussion of organizational approaches and situations along with their applicability in enabling SE for the organization is provided in the article called Systems Engineering Organizational Strategy.

The optimization debate can be handled as described in the book called "Enterprise Architecture as Strategy" (Ross, Weill, and Robertson 2006). In other words, an enterprise can choose (or not) to unify its operations and can choose (or not) to unify its information base. There are different strategies the enterprise might adopt to achieve and sustain value creation (and how ESE helps an enterprise to choose). This is further addressed in the section on Enterprise Architecture Formulation & Assessment in the article called Enterprise Capability Management.

Enabling Systems Engineering in the Organization

SE skills, techniques, and resources are relevant to many enterprise functions, and a well-founded SE capability can make a substantial contribution at the enterprise level, as well as at the project level. The article called Systems Engineering Organizational Strategy discusses enabling SE in the organization, while the article called Enabling Businesses and Enterprises focuses on the cross-organizational functions at the business and enterprise levels. The competence of individuals is discussed in the article called Enabling Individuals.

Kinds of Knowledge Used by the Enterprise

Knowledge is a key resource for ESE. There are generally two kinds of knowledge: explicit and tacit. Explicit knowledge can be written down or incorporated in computer codes. Much of the relevant knowledge, however, is "tacit knowledge" that only exists within the heads of people and in the context of relationships that people form with each other (e.g., team, project, and business level knowledge). The ability of an organization to create value is critically dependent on the people it employs, on what they know, how they work together, and how well they are organized and motivated to contribute to the organization's purpose.

Projects, Programs, and Businesses

The term "program" is used in various ways in different domains. In some domains a team can be called a program (e.g., a customer support team is their customer relationship "program"). In others, an entire business is called a program (e.g., a wireless communications business unit program), and in others the whole enterprise is called a program (e.g., the Joint Strike Fighter program and the Apollo Space program). And in many cases, the terms project and program are used interchangeably with no discernible distinction in their meaning or scope. Typically, but not always, there are program managers who have profit and loss (P&L) responsibility and are the ultimate program decision makers. A program manager may have a portfolio of items (services, products, facilities, intellectual property, etc.) that are usually provided, implemented, or acquired through projects.

The Office of Government Commerce provides a useful distinction between programs and projects:

> *The ultimate goal of a Programme is to realise outcomes and benefits of strategic relevance. To achieve this a programme is designed as a temporary flexible organisation structure created to coordinate, direct and oversee the implementation of a set of related projects and activities in order to deliver outcomes and benefits related to the organisation's strategic objectives...*
>
> *A programme is likely to have a life that spans several years. A Project is usually of shorter duration (a few months perhaps) and will be focussed on the creation of a set of deliverables within agreed cost, time and quality parameters.* (OGC 2010)

Enabling the Enterprise

ESE, by virtue of its inherent trans-disciplinarity (Sage 2000, 158-169) in dealing with problems that are large in scale and scope, can better enable the enterprise to become more effective and efficient. The complex nature of many enterprise problems and situations usually goes beyond the abilities of standard tools and techniques provided to business school graduates (See also Complexity). ESE can augment the standard business management methods using the tools and methods from the SE discipline to more robustly analyze and evaluate the enterprise as a holistic system. A more general viewpoint, or "view," for dealing with the enterprise consisting of scale, granularity, mindset, and time frame is provided by White (2007) and by McCarter and White (2009, 71-105).

ESE can provide the enablers to address the concerns of enterprise executives as shown in Table 1 (Rouse 2009). The methods for dealing with, and the special characteristics of, complex adaptive systems must be properly considered when adapting traditional systems engineering (TSE) practices for use at the enterprise level—many of which come out of the systems science and systems thinking domains (von Bertalanffy 1968; Weinberg and Weinberg 1988; Miller and Page 2007; Rouse 2008, 17-25). For an approach to complex adaptive systems (CAS) engineering, refer to White (2009, 1-16) and to McCarter and White (2009, 71-105).

Table 1. Executive Concerns and SE Enablers (Rouse 2009). Reprinted with permission of John Wiley & Sons Inc. All other rights are reserved by the copyright owner.

Executive Concerns	SE Enablers
Identifying ends, means, and scope and candidate changes	System complexity analysis to compare "as is" and "to be" enterprises
Evaluating changes in terms of process behaviors and performance	Organizational simulation of process flows and relationships
Assessing economics in terms of investments, operating costs, and returns	Economic modeling in terms of cash flows, volatility, and options
Defining the new enterprise in terms of processes and their integration	Enterprise architecting in terms of workflow, processes, and levels of maturity
Designing a strategy to change the culture for selected changes	Organizational and cultural change via leadership, vision, strategy, and incentives
Developing transformation action plans in terms of what, when, and who	Implementation planning in terms of tasks, schedule, people, and information

Enterprise Engineering

Another distinction is that “enterprise design does not occur at a single point in time like the design of most systems. Instead, enterprises evolve over time and are constantly changing, or are constantly *being designed*” (Giachetti 2010) [emphasis in original]. Giachetti calls this new discipline “enterprise engineering.” We consider the enterprise engineering set of practices to be equivalent to what we call enterprise systems engineering (ESE) in this article.

> *The body of knowledge for enterprise engineering is evolving under such titles as enterprise engineering, business engineering, and enterprise architecture . . . . Many systems and software engineering principles are applicable to enterprise engineering, but enterprise engineering’s unique complexities require additional principles…. Enterprise engineering’s intent is to deliver a targeted level of enterprise performance in terms of shareholder value or customer satisfaction . . . . Enterprise engineering methods include modeling; simulation; total quality management; change management; and bottleneck, cost, workflow, and value-added analysis.* (Joannou 2007)

Supersystem Constructs

System of Systems (SoS)

The phrase "system of systems” (SoS) is commonly used, but there is no widespread agreement on its exact meaning, nor on how it can be distinguished from a conventional system. A system is generally understood to be a collection of elements that interact in such a manner that it exhibits behavior that the elements themselves cannot exhibit. Each element (or component) of the system can be regarded as a system in its own right. Therefore, the phrase “system of systems” can technically be used for any system and, as such, would be a superfluous term. However, the meaning of this phrase has been examined in detail by (Maier 1998, 267-284), and his definition has been adopted by some people (AFSAB 2005). Maier provides this definition:

> *A SoS is an assemblage of components which individually may be regarded as systems, and which possess two additional properties:*

- ***Operational Independence of the Components:*** *If the system-of-systems is disassembled into its component systems the component systems must be able to usefully operate independently. That is, the components fulfill customer-operator purposes on their own; and*
- ***Managerial Independence of the Components:*** *The component systems not only can operate independently, they do operate independently. The component systems are separately acquired and integrated but maintain a*

continuing operational existence independent of the system-of-systems. (Maier 1998, 267-284)

Maier goes on further saying that "the commonly cited characteristics of systems-of-systems (complexity of the component systems and geographic distribution) are not the appropriate taxonomic classifiers" (Maier 1998, 267-284). Four kinds of SoS have been defined (Dahmann, Lane, and Rebovich 2008).

For further details on SoS, see the *Systems Engineering Guide for SoS* developed by the US Department of Defense (DoD) (DUS(AT) 2008). Also, see the Systems of Systems (SoS) knowledge area.

Federation of Systems (FoS)

Different from the SoS concept, but related to it in several ways, is the concept called "federation of systems" (FoS). This concept might apply when there is a very limited amount of centralized control and authority (Sage and Cuppan 2001, 325-345; Sage and Rouse 2009). Each system in an FoS is very strongly in control of its own destiny, but "chooses" to participate in the FoS for its own good and the good of the "country," so to speak. It is a coalition of the willing. An FoS is generally characterized by significant autonomy, heterogeneity, and geographic distribution or dispersion (Krygiel 1999). Krygiel defined a taxonomy of systems showing the relationships among conventional systems, SoSs, and FOSs.

This taxonomy has three dimensions: autonomy, heterogeneity, and dispersion. A FoS would have a larger value on each of these three dimensions than a non-federated SoS. An "Enterprise System," as described above, could be considered to be an FoS if it rates highly on these three dimensions. However, it is possible for an enterprise to have components that are not highly autonomous, that are relatively homogeneous, and are geographically close together. Therefore, it would be incorrect to say that an enterprise is necessarily the same as an FoS.

Dove points out that in order for a large enterprise to survive in the twenty-first century, it must be more agile and robust (Dove 1999 and 2001). Handy (1992, 59-67) describes a federalist approach called "New Federalism" which identifies the need for structuring of loosely coupled organizations to help them adapt to the rapid changes inherent in the Information Age. This leads to the need for virtual organizations where alliances can be quickly formed to handle the challenges of newly identified threats and a rapidly changing marketplace (Handy 1995, 2-8). Handy sets out to define a number of federalist political principles that could be applicable to an FoS. Handy's principles have been tailored to the domain of systems engineering (SE) and management by Sage and Cuppan (2001, 325-345):

- Subsidiarity,
- Interdependence,
- Uniform and standardized way of doing business,
- Separation of powers,
- Dual citizenship, and
- Scales of SE.

Scales of SE

According to Maier's definition, not every enterprise would be called a SoS since the systems within the enterprise do not usually meet the criteria of operational and managerial independence. In fact, one of the key purposes of an enterprise is to explicitly establish operational dependence between systems that the enterprise owns and/or operates in order to maximize the efficiency and effectiveness of the enterprise as a whole. Therefore, it is more proper to treat an enterprise system and an SoS as different types of things, with different properties and characteristics. This distinction is illustrated in the figure below, where three corresponding categories of SE are shown (DeRosa 2005; Swarz et al. 2006).

It is true that an enterprise can be treated as a system itself and is comprised of many systems within the enterprise, but this discussion will reserve the term SoS to those systems that meet the criteria of operational and managerial independence. This distinction was also used within the MITRE Corporation in their ESE Office (Rebovich and White 2011).

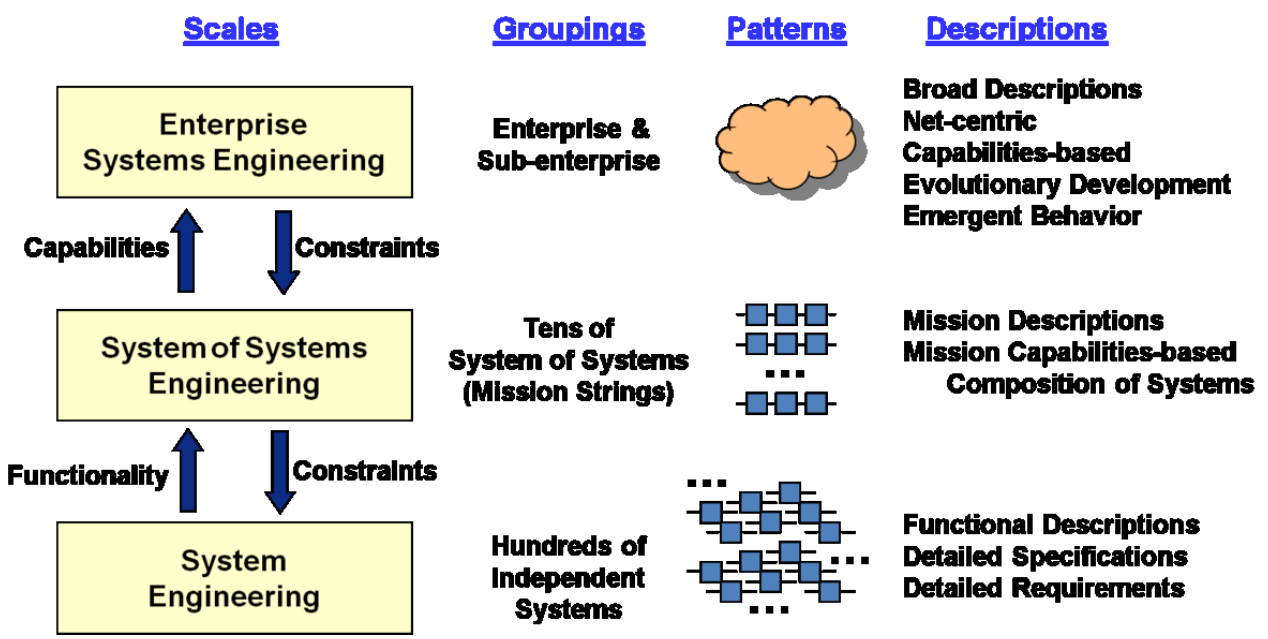

Figure 2. Different Groupings and Patterns Revealed at Different Scales (DeRosa 2005). Reprinted with permission of © 2011. The MITRE Corporation. All Rights Reserved. All other rights are reserved by the copyright owner.

Relationships between Enterprise and SoS

An enterprise may require a particular operational capability that is brought into being by connecting together a chain of systems that together achieve that capability. Any one of these systems in the chain cannot by itself provide this capability. The desired capability is the emergent property of this chain of systems. This chain of systems is sometimes called an SoS. However, the enterprise that requires this capability rarely has direct control over all the systems necessary to provide this full capability. This situation is illustrated in the figure below (Martin 2010).

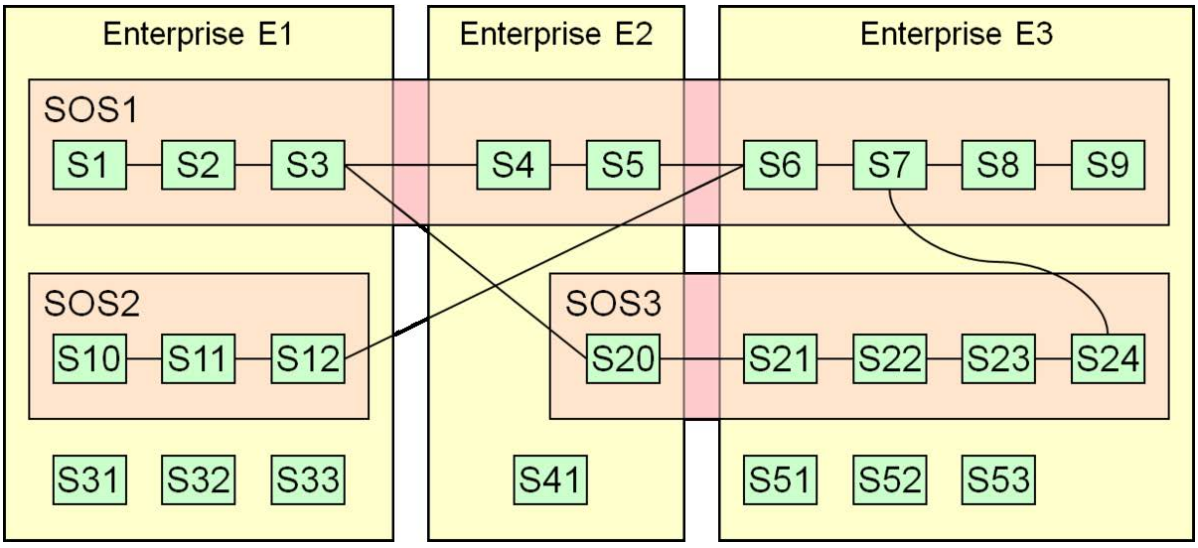

Figure 3. Relationships Between an Enterprise and SoSs (Martin 2010). Reprinted with permission of The Aerospace Corporation. All other rights are reserved by the copyright owner.

Enterprise E1 (in the example above) has full control over SoS2, but not full control over SoS1. TSE can be applied to the individual systems (S1, S2, …, S53) shown within each enterprise, but needs to be augmented with additional activities to handle SoS and enterprise kinds of issues.

There is a general issue regarding dealing with enterprises in this situation: there are at least two enterprises related to any particular SoS. First, there is the enterprise of builders/developers comprising projects and programs, which have to be organized appropriately and adopt special types of architectural principles. Second, there is the enterprise of users (those who use the products and service provided by the first enterprise), which has to exercise its own sort of agility. How the first enterprise designs systems to allow the second to operate is the core issue.

Related Business Activities

- Lead Authors:
- James Martin, Dick Fairley, and Bud Lawson

-

The following business management activities can be supported by enterprise systems engineering (ESE) activities:

- mission and strategic planning,
- business processes and information Management,
- performance management,
- portfolio management,
- resource allocation and budgeting, and
- program and project management.

Introduction

The figure below shows how these business activities relate to each other as well as the relative scope of ESE and product systems engineering (PSE) (Martin 2010 and 2011). PSE is mainly involved at the project level and collaborates with project management activities, and gets somewhat involved in program management and the resource allocation and budgeting activities. On the other hand, ESE is heavily involved in the higher level activities from the program management level and up. Both ESE and PSE have key roles to play in the enterprise.

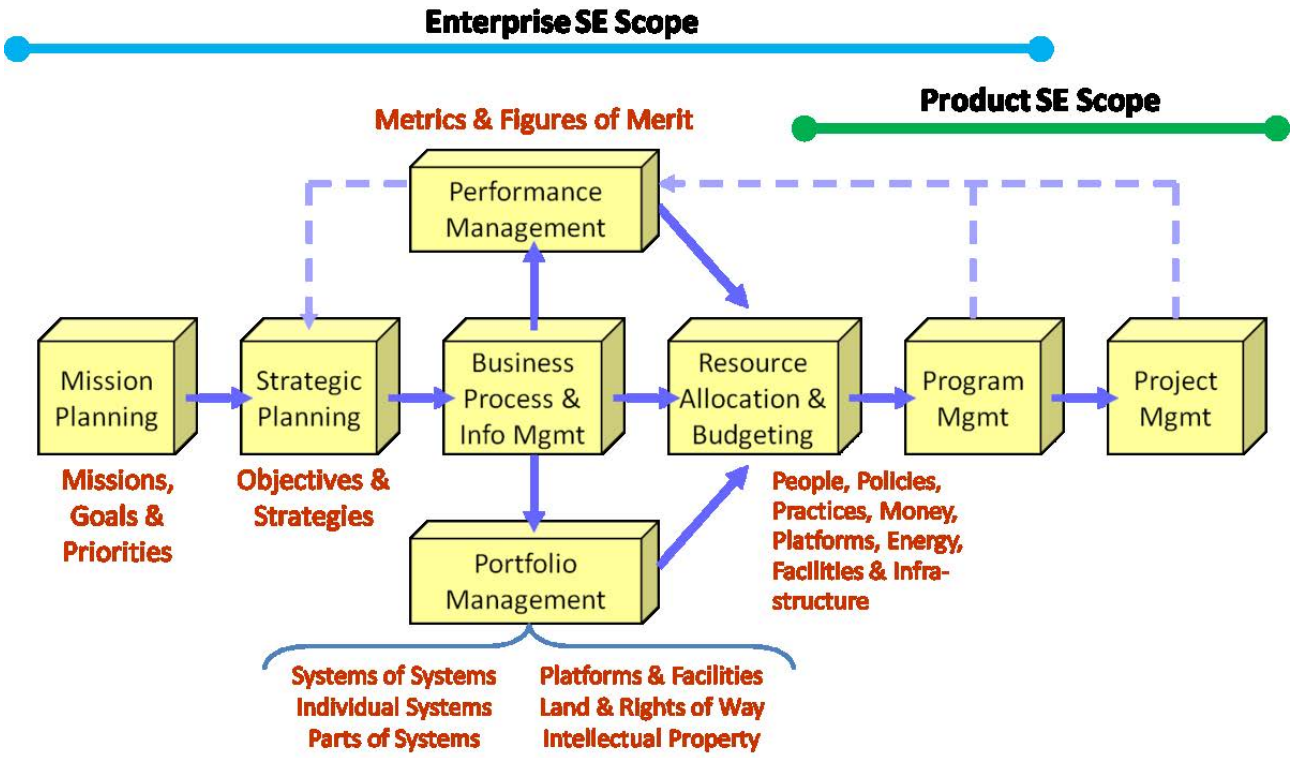

Figure 1. Related Business Activities (Martin 2010). Reprinted with permission of The Aerospace Corporation. All other rights are reserved by the copyright owner.

Shown in this manner, these business activities can be considered to be separate processes with a clear precedence in terms of which process drives other processes. TSE uses “requirements” to specify the essential features and functions of a system. An enterprise, on the other hand, typically uses goals and objectives to specify the fundamental characteristics of desired enterprise operational capabilities. The enterprise objectives and strategies are used in portfolio management to discriminate between options and to select the appropriate balanced portfolio of systems and other enterprise resources.

The first three activities listed above are covered in Enabling Businesses and Enterprises. The other business management activities are described in more detail below in regards to how they relate to ESE.

Business Management Cycles

PDCA stands for "plan-do-check-act" and is a commonly used iterative management process as seen in the figure below. It is also known as the Deming circle or the Shewhart cycle after its two key proponents (Deming 1986; Shewhart 1939). ESE should use the PDCA cycle as one of its fundamental tenets. For example, after ESE develops the enterprise transformation plan, execution of the planned improvements are monitored (i.e., “checked” in the PDCA cycle) to ensure they achieve the targeted performance levels. If not, then action needs to be taken (i.e., “act” in the PDCA cycle) to correct the situation and re-planning may be required. ESE can also use the PDCA cycle in its support of the 'business as usual' efforts, such as the annual budgeting and business development planning activities.

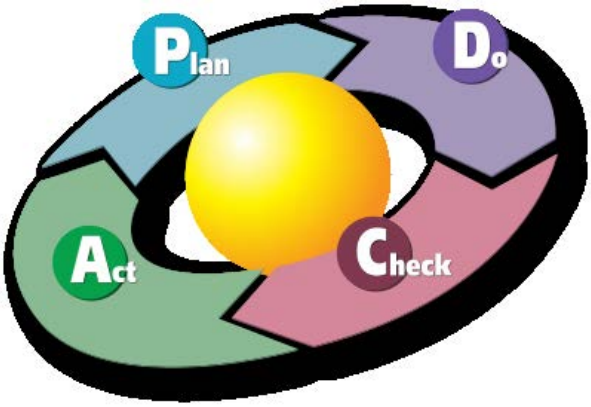

Figure 2. PDCA Cycle. (Source: http://en.wikipedia.org/wiki/PDCA.Accessed July 2010. Diagram by Karn G. Bulsuk (http://blog.bulsuk.com).Used through a CC BY 3.0 license (http://creativecommons.org/licenses/by/3.0/).

It is also worth mentioning the utility of using Boyd's OODA loop (observe, orient, decide, and act) to augment PDCA. This could be accomplished by first using the OODA loop (http://en.wikipedia.org/wiki/OODA_loop), which is continuous in situation awareness, and then followed by using the PDCA approach, which is discrete, having goals, resources, usually time limits, etc. (Lawson 2010).

Portfolio Management

Program and project managers direct their activities as they relate to the systems under their control. Enterprise management, on the other hand, is involved in directing the portfolio of items that are necessary to achieving the enterprise goals and objectives. This can be accomplished by using portfolio management:

> *Project Portfolio Management (PPM) is the centralized management of processes, methods, and technologies used by project managers and project management offices (PMOs) to analyze and collectively manage a group of current or proposed projects based on numerous key characteristics. The objectives of PPM are to determine the optimal resource mix for delivery and to schedule activities to best achieve an organization's operational and financial goals—while honoring constraints imposed by customers, strategic objectives, or external real-world factors.* (http:/ / en. wikipedia. org/ wiki/ Project_portfolio_management)

The enterprise may not actually own these portfolio items. They could rent or lease these items, or they could have permission to use them through licensing or assignment. The enterprise may only need part of a system (e.g., one bank of switching circuits in a system) or may need an entire system of systems (SoS) (e.g., switching systems, distribution systems, billing systems, provisioning systems, etc.). Notice that the portfolio items are not just those items related to the systems that systems engineering (SE) deals with. These could also include platforms (like ships and oil drilling derricks), facilities (like warehouses and airports), land and rights of way (like railroad property easements and municipal covenants), and intellectual property (like patents and trademarks).

The investment community has been using portfolio management for a long time to manage a set of investments to maximize return for a given level of acceptable risk. These techniques have also been applied to a portfolio of "projects" within the enterprise (Kaplan 2009). However, it should be noted that an enterprise is not merely a portfolio of projects. The enterprise portfolio consists of whatever systems, organizations, facilities, intellectual property, and other resources that are needed to help the enterprise achieve its goals and objectives.

Portfolio management in the context of ESE is well addressed in the following article: http://www.mitre.org/work/ systems_engineering/ guide/ enterprise_engineering/ enterprise_planning_management/ portfolio_management.html (MITRE 2010).

Resource Allocation and Budgeting

The resource allocation and budgeting (RA&B) activity is driven by the portfolio management definition of the optimal set of portfolio elements. Capability gaps are mapped to the elements of the portfolio, and resources are assigned to programs (or other organizational elements) based on the criticality of these gaps. Resources come in the form of people and facilities, policies and practices, money and energy, and platforms and infrastructure. Allocation of resources could also involve the distribution or assignment of corporate assets, like communication bandwidth, manufacturing floor space, computing power, intellectual property licenses, and so on. Resource allocation and budgeting is typically done on an annual basis, but more agile enterprises will make this a more continuous process. Some of the resource allocation decisions deal with base operational organizations that are not project related.

It is sometimes the case that RA&B is part of portfolio management (PfM). But as can be seen in Figure 1, it is sometimes useful and practical to separate these two activities. PfM usually recommends changes to the enterprise portfolio, but RA&B takes these PfM considerations into mind along with inputs from the business process and information management and the performance management activities. Furthermore, PfM is usually an annual or biannual activity whereas RA&B is often done more frequently. RA&B may need to execute *ad hoc* when perturbations happen, such as funding cuts, schedule slips, performance targets missed, strategic goals changed, and so on.

Program and Project Management

Within the enterprise, TSE is typically applied inside a project to engineer a single system (or perhaps a small number of related systems). If there is a SoS or a large, complex individual system to be engineered, then this might be handled at the program level, but is sometimes handled at the project level, depending on the size and complexity of the system-of-interest (See also Complexity).

There are commonly three basic types of projects in an enterprise. A development project takes a conceptual notion of a system and turns this into a realizable design. A production project takes the realizable design for a system and turns this into physical copies (or instantiations). An operations “project” directly operates each system or supports the operation by others. (Base operations are sometimes called "line organizations" and are not typically called projects per se, but should nonetheless be considered as key elements to be considered when adjusting the enterprise portfolio.) The operations project can also be involved in maintaining the system or supporting maintenance by others. A program can have all three types of projects active simultaneously for the same system, as in this example:

- Project A is developing System X version 3.
- Project B is operating and maintaining System X version 2.
- Project C is maintaining System X version 1 in a warehouse as a backup in case of emergencies.

Project management uses TSE as a tool to ensure a well-structured project and to help identify and mitigate cost, schedule, and technical risks involved with system development and implementation. The project level is where the TSE process is most often employed (Martin 1997; ISO/IEC/IEEE 2015; Wasson 2006; INCOSE 2010; Blanchard and Fabrycky 2010).

The Office of Government Commerce provides a useful distinction between programs and projects:

> *The ultimate goal of a Programme is to realise outcomes and benefits of strategic relevance. To achieve this, a programme is designed as a temporary flexible organisation structure created to coordinate, direct and oversee the implementation of a set of related projects and activities in order to deliver outcomes and benefits related to the organisation’s strategic objectives...*
>
> *A programme is likely to have a life that spans several years. A Project is usually of shorter duration (a few months perhaps) and will be focussed on the creation of a set of deliverables within agreed cost, time and quality parameters.* (OGC 2010)

Enterprise Governance

ESE is also concerned with the way in which organizations and embedded management and technical functions work together to achieve success at the enterprise level. Governance frameworks provide the essential additional structure and controls needed to both 'steer a steady ship' (during business as usual) and to 'plot a course to a new place' (during business transformation).

Such frameworks can be designed by recognizing that there are enduring management concerns that need to be addressed and by applying the principle of economy. For example, a particular concern for most organizations is linking the control of projects to business drivers and objectives. This leads to a requirement for a governance body to both approve the initiation of projects, and to regularly review their progress, continuing relevance, and if necessary, mutual coherence in the light of developments inside and outside the enterprise.

This might be achieved by delegating some or all of the roles; depending on circumstances, the enterprise might be driven towards top-down or a more collective, peer-to-peer approach—or even a combination of the two for different functions. Governance bodies and management roles can be engineered in this way against a common set of management concerns. Governance may also include the maintenance of common technical standards and their promulgation and use throughout relevant projects. See Bryant (2012) for more information on governance.

Multi-Level Enterprises

An enterprise does not always have full control over the ESE processes. In some cases, an enterprise may have no direct control over the resources necessary to make programs and projects successful. For example, the Internet Engineering Task Force (IETF) is responsible for the "smooth operation of the Internet," yet it controls none of the requisite resources.

> *The Internet Engineering Task Force (IETF) is a large open international community of network designers, operators, vendors, and researchers concerned with the evolution of the Internet architecture and the smooth operation of the Internet. … The actual technical work of the IETF is done in its working groups, which are organized by topic into several areas (e.g., routing, transport, security, etc.). Much of the work is handled via mailing lists. The IETF holds meetings three times per year.* (IETF 2010a)

The IETF has "influence" over these resources even though it does not have direct control: "The IETF is unusual in that it exists as a collection of happenings, but is not a corporation and has no board of directors, no members, and no dues" (IETF 2010b).

The ESE processes might be allocated between a "parent" enterprise and "children" enterprises, as shown in the figure below (Martin 2010). The parent enterprise, in this case, has no resources. These resources are owned by the subordinate child enterprises. Therefore, the parent enterprise does not implement the processes of resource allocation and budgeting, program management, and project management.

The parent enterprise may have an explicit contract with the subordinate enterprises, or, as in some cases, there is merely a "working relationship" without the benefit of legal obligations. The parent enterprise will expect performance feedback from the lower level to ensure that it can meet its own objectives. Where the feedback indicates a deviation from the plan, the objectives can be adjusted or the portfolio is modified to compensate.

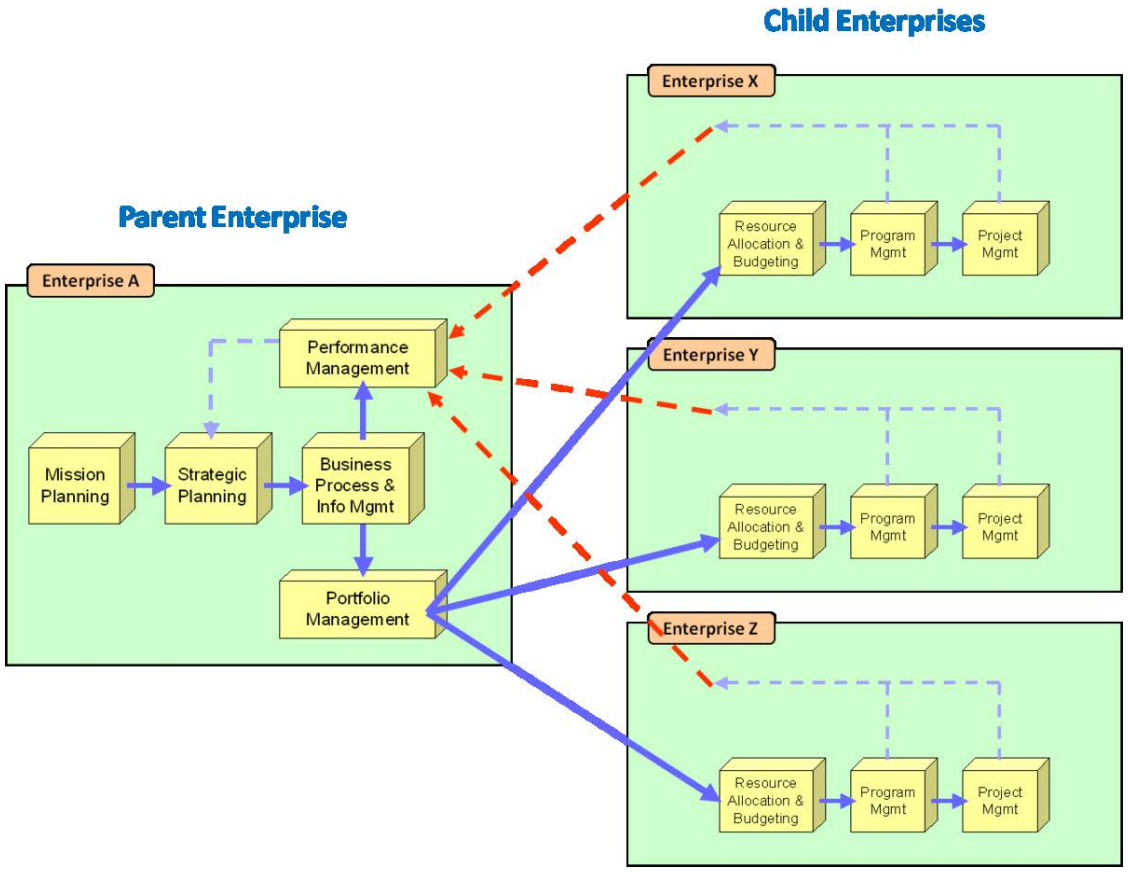

Figure 3. Parent and Child Enterprise Relationships (Martin 2010). Reprinted with permission of The Aerospace Corporation. All other rights are reserved by the copyright owner.

Enterprises X, Y, and Z in the situation shown above will cooperate with each other to the extent that they honor the direction and guidance from the parent enterprise. These enterprises may not even be aware of each other, and, in this case, would be unwittingly cooperating with each other. The situation becomes more complex if each enterprise has its own set of strategic goals and objectives as shown in the figure below.

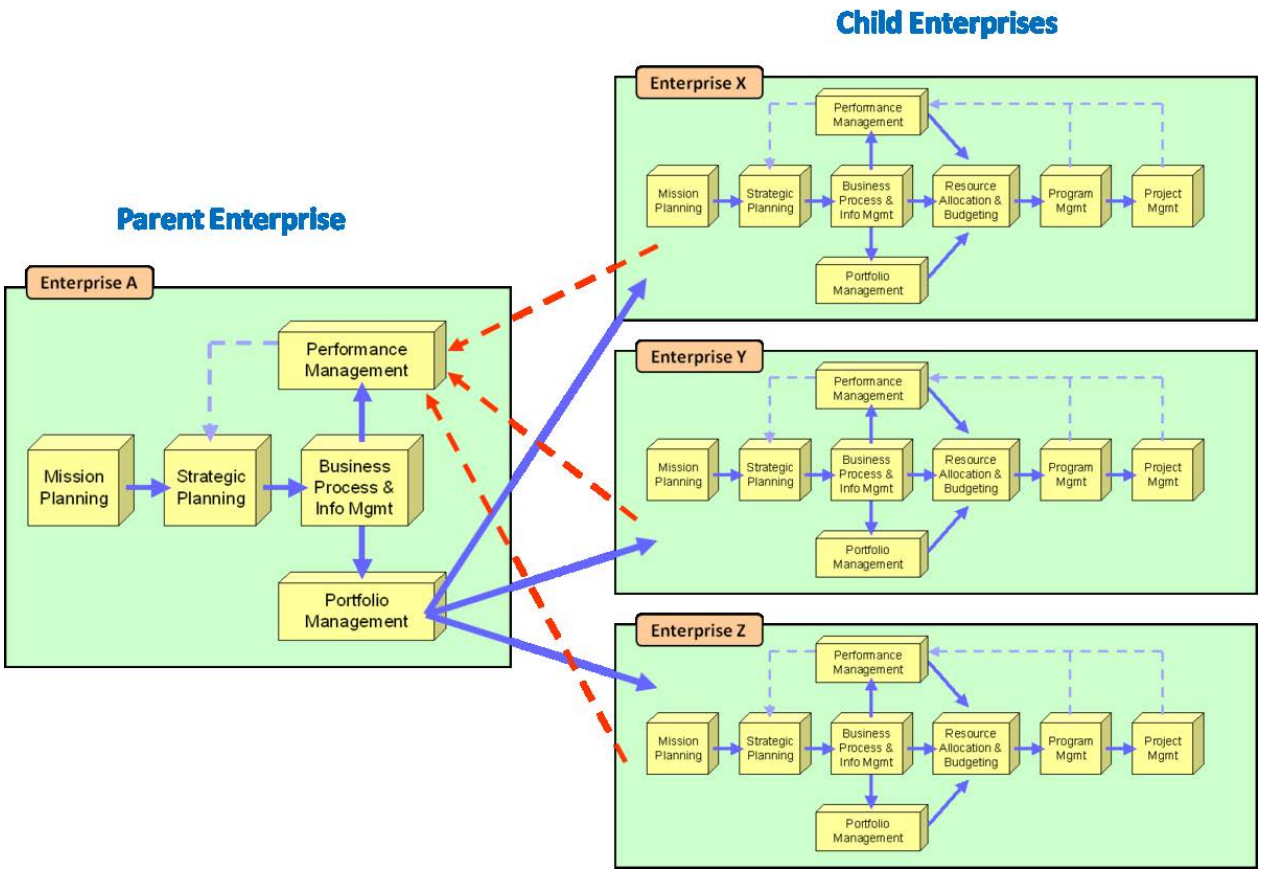

Figure 4. Mission and Strategic Planning at All Levels of Cooperating Enterprises (Martin 2010). Reprinted with permission of The Aerospace Corporation. All other rights are reserved by the copyright owner.

These separate, sub-enterprise objectives will sometimes conflict with the objectives of the parent enterprise. Furthermore, each subordinate enterprise has its own strategic objectives that might conflict with those of its siblings. The situation shown here is not uncommon, and illustrates an enterprise of enterprises, so to speak. This highlights the need for the application of SE at the enterprise level to handle the complex interactions and understand the overall behavior of the enterprise as a whole. TSE practices can be used, to a certain extent, but these need to be expanded to incorporate additional tools and techniques.

Enterprise Systems Engineering Key Concepts

- Lead Authors:
- James Martin, Bud Lawson, and Alan Faisandier

-

The purpose of traditional systems engineering (TSE) is to bring together a diversity of discipline experts to address a wide range of problems inherent in the development of a large, complex "single" system (Blanchard and Fabrycky 2010; Hall 1989; Sage and Rouse 2009). Enterprise systems engineering (ESE) expands beyond this traditional basis to "consider the full range of SE services increasingly needed in a modern organization where information-intensive systems are becoming central elements of the organization's business strategy" (Carlock and Fenton 2001, 242-261). The traditional role of systems engineering (SE) is heavily involved in system acquisition and implementation, especially in the context of government acquisition of very large, complex military and civil systems (e.g., F22 fighter jet and air traffic control systems).

ESE encompasses this traditional role in system acquisition, but also incorporates enterprise strategic planning and enterprise investment analysis (along with others as described below). These two additional roles for SE at the enterprise level are "shared with the organization's senior line management, and tend to be more entrepreneurial, business-driven, and economic in nature in comparison to the more technical nature of classical systems engineering" (Carlock and Fenton 2001, 242-261).

Closing the Gap

ESE practices have undergone significant development recently.

> *Today the watchword is enterprise systems engineering, reflecting a growing recognition that an 'enterprise' may comprise many organizations from different parts of government, from the private and public sectors, and, in some cases, from other nations.* (MITRE 2004)

Rebovich (2006) says there are "new and emerging modes of thought that are increasingly being recognized as essential to successful systems engineering in enterprises." For example, in addition to the TSE process areas, MITRE has included the following process areas in their ESE process (DeRosa 2005) to close the gap between ESE and PSE:

- strategic technical planning,
- enterprise architecture,
- capabilities-based planning analysis,
- technology planning, and
- enterprise analysis and assessment.

These ESE processes are shown in the context of the entire enterprise in the figure below (DeRosa 2006). The ESE processes are shown in the middle with business processes on the left and TSE processes on the right. These business processes are described in the article called Related Business Activities. The TSE processes are well documented in many sources, especially in the ISO/IEC/IEEE 15288 standard (2015).

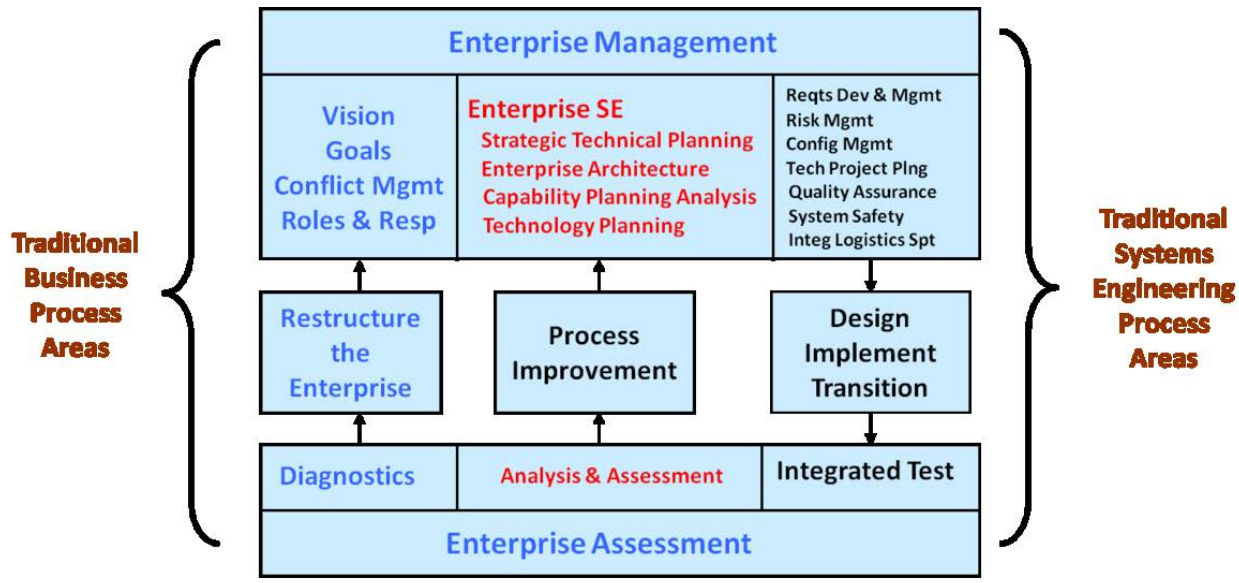

Figure 1. Enterprise SE Process Areas in the Context of the Entire Enterprise (DeRosa 2006).

SE is viewed by many organizations and depicted in many process definitions as bounded by the beginning and end of a system development project. In MITRE, this restricted definition was referred to as TSE. Many have taken a wider view seeking to apply SE to the “whole system” and “whole life cycle.” For example, Hitchins (1993) sets out a holistic, whole-life, wider system view of SE centered on operational purpose. Elliott and Deasley (2007) discuss the differences between development phase SE and in-service SE.

In contrast to TSE, the ESE discipline is more like a “regimen” (Kuras and White 2005) that is responsible for identifying “outcome spaces,” shaping the development environment, coupling development to operations, and rewarding results rather than perceived promises (DeRosa 2005). ESE must continually characterize the operational environmental and the results of enterprise or SoS interventions to stimulate further actions within and among various systems in the enterprise portfolio. Outcome spaces are characterized by a set of desired capabilities that help meet enterprise objectives, as opposed to definitive “user requirements” based on near-term needs. Enterprise capabilities must be robust enough to handle unknown threats and situations in the future. A detailed description of previous MITRE views on ESE can be found in a work by Rebovich and White (2011).

Role of Requirements in ESE

TSE typically translates user needs into system requirements that drive the design of the system elements. The system requirements must be “frozen” long enough for the system components to be designed, developed, tested, built, and delivered to the end users (which can sometimes take years, and in the case of very large, complicated systems like spacecraft and fighter jets, more than a decade).

ESE, on the other hand, must account for the fact that the enterprise must be driven not by requirements (that rarely can even be defined, let alone made stable), but instead by continually changing organizational visions, goals, governance priorities, evolving technologies, and user expectations. An enterprise consists of people, processes, and technology where the people act as “agents” of the enterprise:

> *Ackoff has characterized an enterprise as a 'purposeful system' composed of agents who choose both their goals and the means for accomplishing those goals. The variety of people, organizations, and their strategies is what creates the inherent complexity and non-determinism in an enterprise. ESE must account for the concerns, interests and objectives of these agents.* (Swarz, DeRosa, and Rebovich 2006) (See also Complexity)

Whereas TSE focuses on output-based methodologies (e.g., functional analysis and object-oriented analysis), ESE is obligated to emphasize outcomes (e.g., business analysis and mission needs analysis), especially those related to the enterprise goals and key mission needs.

Enterprise Entities and Relationships

An enterprise "system" has different entities and relationships than you might find in a product/service system (see note 1). These can be usefully grouped into two categories: asset items and conceptual items. An example of an asset is hardware and software. Examples of conceptual items are things like analysis, financial elements, markets, policies, process, and strategy.

> *Note 1. An "enterprise system" should not be confused with the enterprise "perceived as a system." An enterprise system is a product (or service) system used across the enterprise, such as payroll, financial accounting, or enterprise resource planning applications, and consolidated data center, data warehouse, and other such facilities and equipment used across one or more organizations.*

Products and services are sometimes treated as "assets" as shown in the figure below (Troux 2010). This categorization of enterprise items comes from the semantic model (i.e., metamodel) used in the Troux Architect modeling tool for characterization and analysis of an enterprise architecture. Other enterprise entities of interest are things like information, knowledge, skills, finances, policies, process, strategy, markets, and resources, but these are categorized as "concept" items (in this particular schema). Further details on how to use this metamodel's entities and relationships are provided by Reese (2010).

Table 1. Asset Domain and Concept Domain Categories for Enterprise Entities. (Troux 2010) Reprinted with permission of Copyright © 2010 Troux Technologies. All other rights are reserved by the copyright owner.

Asset Domains	Concept Domains
Application and Software Domain Data Domain Document Domain Infrastructure and Hardware Domain IT Product Domain IT Service Domain Location Domain Organization Domain Product and Service Domain Services Portfolio Management Domain	Analysis Domain Financial Domain General Domain Information Domain IT Architecture Domain Knowledge and Skill Domain Market Domain Policy Domain Process Domain Resource Domain Strategy Domain Timeline Domain Transition Domain

The application/software and infrastructure/hardware domains are likely the most familiar to systems engineers (as illustrated in the figure below). The application/software domain contains things like the deployed software itself, plus applications, modules, servers, patches, functions, and messages. The infrastructure/hardware domain contains things like the hardware itself, plus networks and different kinds of hardware like computing hardware, cabinets, and network devices. There might be different subtypes of computing hardware like computers, servers, desktops, laptops, and mainframes. You can see from this elaboration of these domains that an enterprise architecture "schema" can be quite extensive in the kinds of things it can model.

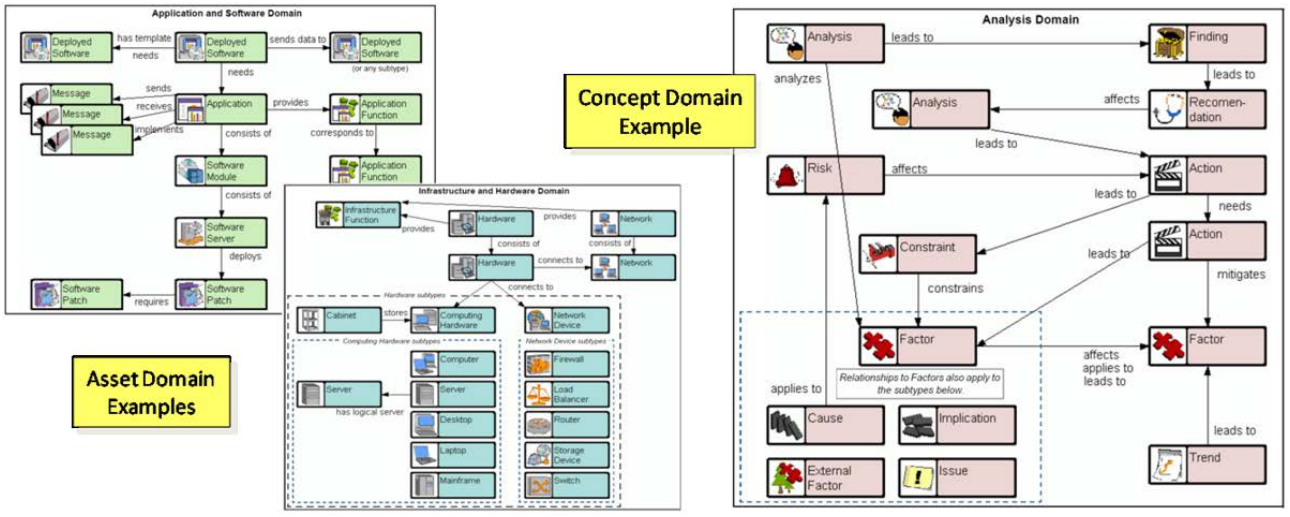

Figure 2. Example of Enterprise Entities & Relationships (Troux 2010). Reprinted with permission of Copyright © 2010 Troux Technologies. All other rights are reserved by the copyright owner.

The less technical domains would be things like policy, market, strategy, transition, financial, knowledge and skill, and analysis. In a typical enterprise architecture schema like this, there could be over a hundred types of modeling objects grouped into these domains. The examples give above are from the Troux Semantics metamodel used in the Troux Architect modeling tool for enterprise architecture activities. Other enterprise modeling tools have similar metamodels (sometimes called "schemas"). See Reese (2010) for more details on how to use the metamodel shown in the figure above.

Enterprise Architecture Frameworks & Methodologies

Enterprise architecture frameworks are collections of standardized viewpoints, views, and models that can be used when developing architectural descriptions of the enterprise. These architecture descriptions can be informal, based on simple graphics and tables, or formal, based on more rigorous modeling tools and methods. ISO/IEC 42010 (2011) specifies how to create architecture descriptions.

These frameworks relate to descriptive models of an enterprise, with conventions agreed in particular communities. There are various frameworks and methodologies available that assist in the development of an enterprise architecture.

Urbaczewski and Mrdalj (2006) provide an overview and comparison of five prominent architectural frameworks, including:

- the Zachman Framework for Enterprise Architecture (Zachman 1992),
- the Department of Defense Architecture Framework (DoDAF) (DoD 2010),
- the Federal Enterprise Architecture Framework (FEAF) (FEA 2001),
- the Treasury Enterprise Architecture Framework (TEAF) (US Treasury 2000),
- and The Open Group Architectural Framework (TOGAF) (TOGAF 2009).

Enterprise Systems Engineering Process Activities

- Lead Authors:
- James Martin, Bud Lawson, and Alan Faisandier

-

The application of the key concepts of Enterprise Systems Engineering requires processes. These processes span and can transform the enterprise.

Systems Engineering Role in Transforming the Enterprise

Enabling Systematic Enterprise Change

The systems engineering (SE) process as applied to the enterprise as a whole could be used as the "means for producing change in the enterprise … [where the] … Seven Levels of change in an organization [are defined] as effectiveness, efficiency, improving, cutting, copying, differentiating and achieving the impossible" (McCaughin and DeRosa 2006). The essential nature of enterprise systems engineering (ESE) is that it "determines the balance between complexity and order and in turn the balance between effectiveness and efficiency. When viewed as the fundamental mechanism for change, it goes beyond efficiency and drives adaptation of the enterprise" (McCaughin and DeRosa 2006). McCaughin and DeRosa (2006) provide a reasonably good definition for an enterprise that captures this notion of balance:

> *Enterprise: People, processes and technology interacting with other people, processes and technology, serving some combination of their own objectives, those of their individual organizations and those of the enterprise as a whole.*

Balancing Effectiveness versus Efficiency

Ackoff tells us that:

> *Data, information, knowledge and understanding enable us to increase efficiency, not effectiveness. The value of the objective pursued is not relevant in determining efficiency, but it is relevant in determining effectiveness. Effectiveness is evaluated efficiency. It is efficiency multiplied by value.* ***Intelligence*** *is the* ***ability to increase efficiency****;* ***wisdom*** *is the* ***ability to increase effectiveness****.*
>
> *The difference between efficiency and effectiveness is reflected in the difference between development and growth. Growth does not require an increase in value; development does. Therefore, development requires an increase in* ***wisdom as well as understanding, knowledge and information****.* ((Ackoff 1989, 3-9), emphasis added)

ESE has a key role to play in establishing the right balance between effectiveness and efficiency in enterprise operations and management. Value stream analysis is one technique, among others, that can help ESE determine where inefficiencies exist or ineffective results are being achieved.

Value Stream Analysis

Value stream analysis is one way of treating the enterprise as a system. It provides insights regarding where in the sequence of enterprise activities value is added as it moves towards the final delivery to customer or user (Rother and Shook 1999). It relates each step to the costs entailed in that step in terms of resource consumption (i.e., money, time, energy, and materials). In addition to direct costs, there may also be indirect costs due to overhead factors or infrastructure elements. This activity commonly involves drawing a flowchart of the value stream for the enterprise

as illustrated in the figure below.

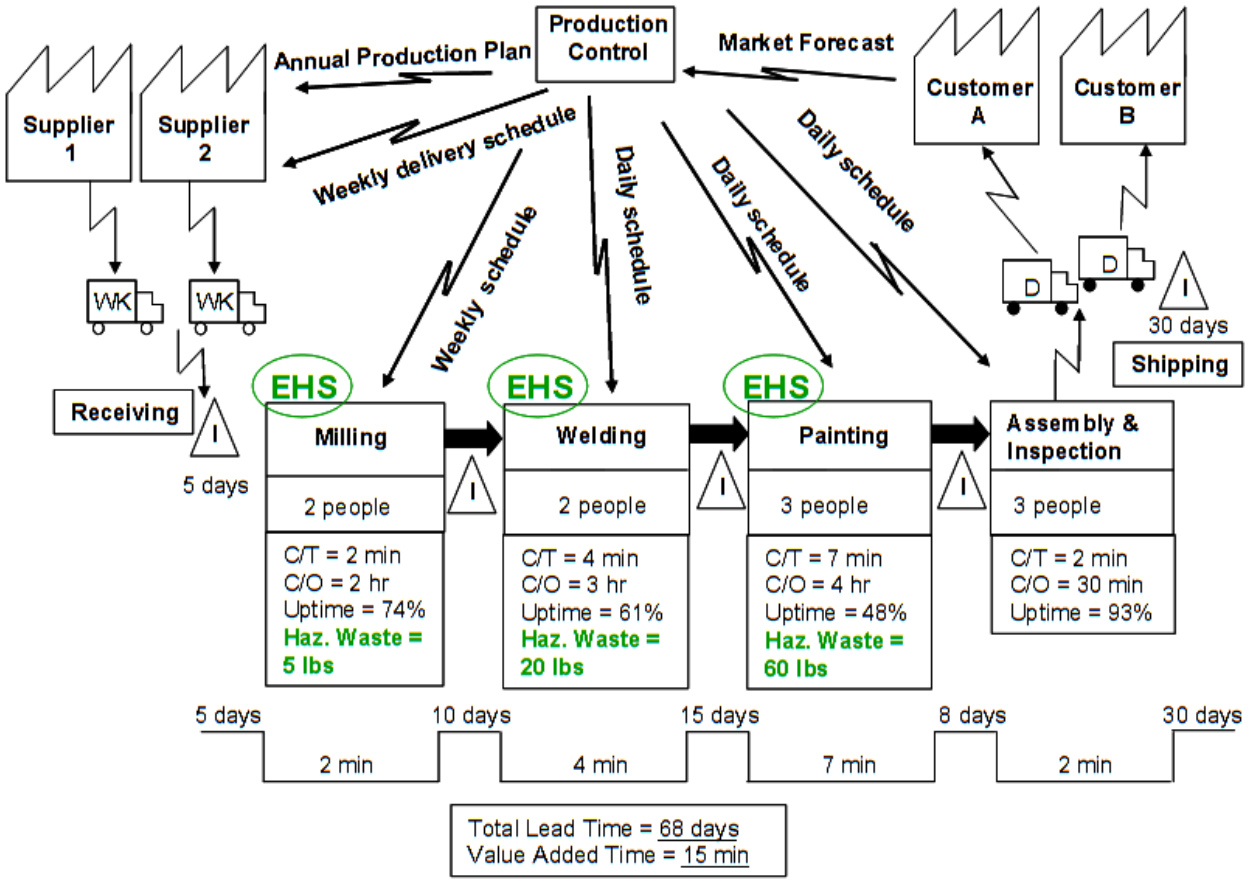

Figure 1. Value Stream Example. (Source: http://en.wikipedia.org/wiki/Value_stream_mapping Accessed September 6, 2010. US EPA Lean and Environment Toolkit, Public Domain.)

Analysis of this value stream diagram can highlight unnecessary space, excessive distance traveled, processing inefficiencies, and so on. Value stream mapping is associated with so-called “lean enterprise” initiatives. At Toyota, where the technique originated, it is known as “material and information mapping” (Rother 2009). Various value stream mapping tools are available (Hines and Rich 1997).

Enterprise Management Process Areas

Martin (2010) has determined that the following four processes are needed in ESE beyond the traditional SE processes in support of enterprise management activities:

1. Strategic technical planning,
2. Capability-based planning analysis,
3. Technology and standards planning, and
4. Enterprise evaluation and assessment.

The interactions between these four processes are illustrated below, along with their interactions with other processes that deal with architecture, requirements, risk, and opportunity.

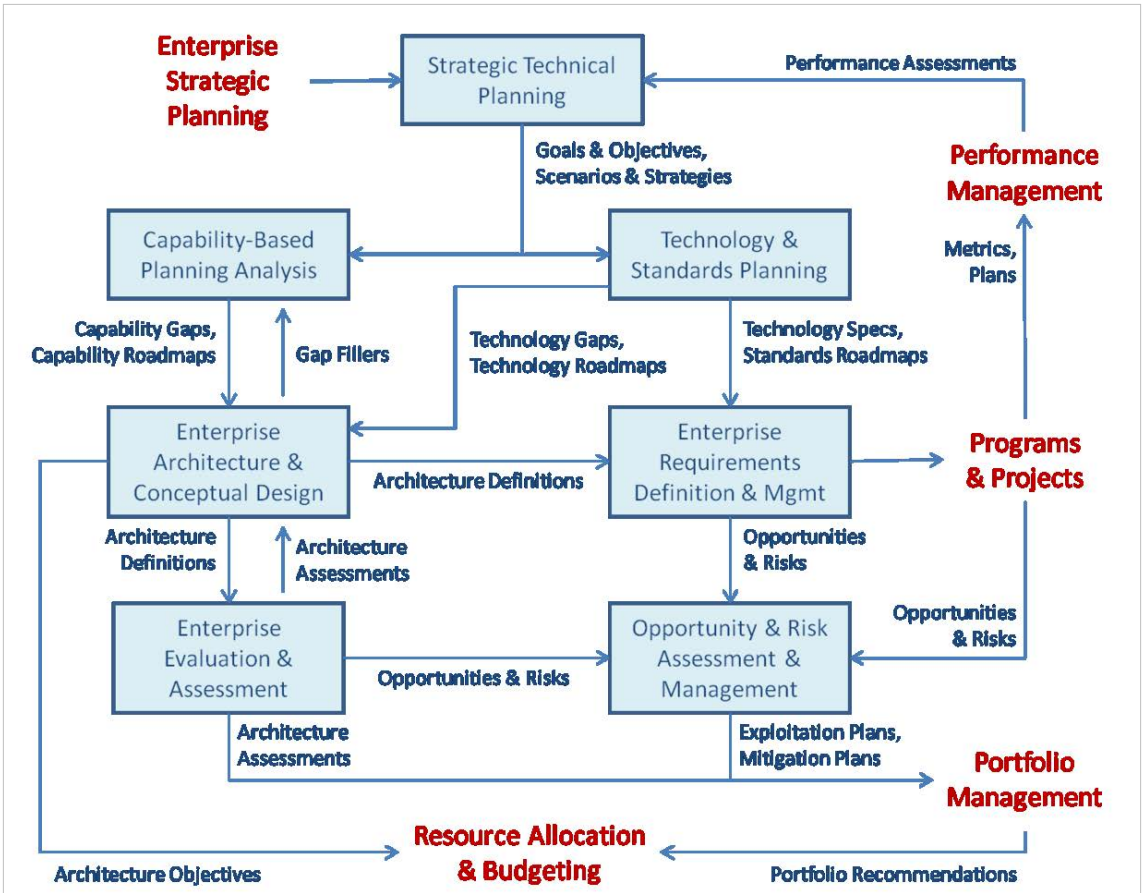

Figure 2. Enterprise Systems Engineering Process Activities. (SEBoK Original)

Strategic Technical Planning

The purpose of strategic technical planning (STP) is to establish the overall technical strategy for the enterprise. It creates the balance between the adoption of standards (see also Systems Engineering Standards) and the use of new technologies, along with consideration of the people aspects driven by the relevant trans-disciplinary technical principles and practices from psychology, sociology, organizational change management, etc.

This process uses the roadmaps developed during technology and standards planning (TSP). It then maps these technologies and standards against the capabilities roadmap to determine potential alignment and synergy. Furthermore, lack of alignment and synergy is identified as a risk to avoid or an opportunity to pursue in the technical strategy. The technical strategy is defined in terms of implementation guidance for the programs and projects.

One reason that STP and TSP are separate processes is that they are often done by different groups in the enterprise and they involve different skill sets. TSP is often done by the technology and science groups. TSP is done closer to (if not in) the chief architect and budget planning groups. Sometimes the great technology proposed by TSP just doesn't line up with the capabilities needed in the requisite time frame. STP does this balancing between technology push and capability pull.

Capability-Based Planning Analysis

The purpose of *Capability-based Planning Analysis* is to translate the enterprise vision and goals into a set of current and future capabilities that helps achieve those goals. Current missions are analyzed to determine their suitability in supporting the enterprise goals. Potential future missions are examined to determine how they can help achieve the vision. Current and projected capabilities are assessed to identify capability gaps that prevent the vision and technical strategy from being achieved. These capability gaps are then used to assess program, project, and system opportunities that should be pursued by the enterprise. This is defined in terms of success criteria of what the enterprise is desired to achieve.

There are different types of capabilities, as shown in the figure below. It is common practice to describe capabilities in the form of capability hierarchies and capability roadmaps. Technology roadmaps (discussed below under Technology Planning) are usually related to the system capabilities while business capability roadmaps (BCRMs) are related to the operational capabilities of the enterprise as a whole (ref: Business-Capability Mapping: Staying Ahead of the Joneses, http://msdn.microsoft.com/en-us/library/bb402954.aspx). The BCRM development is usually done as part of enterprise strategic planning, which is one level higher than, and a key driver for, the strategic technical planning activity described above.

In some domains there may be competency roadmaps dealing with the organizational capabilities, with perhaps the desired competency levels of individuals mapped out in terms of the jobs or roles used in the enterprise or perhaps in terms of the knowledge and skills required for certain activities. (For more information on systems engineering competency, see the Enabling Individuals article.)

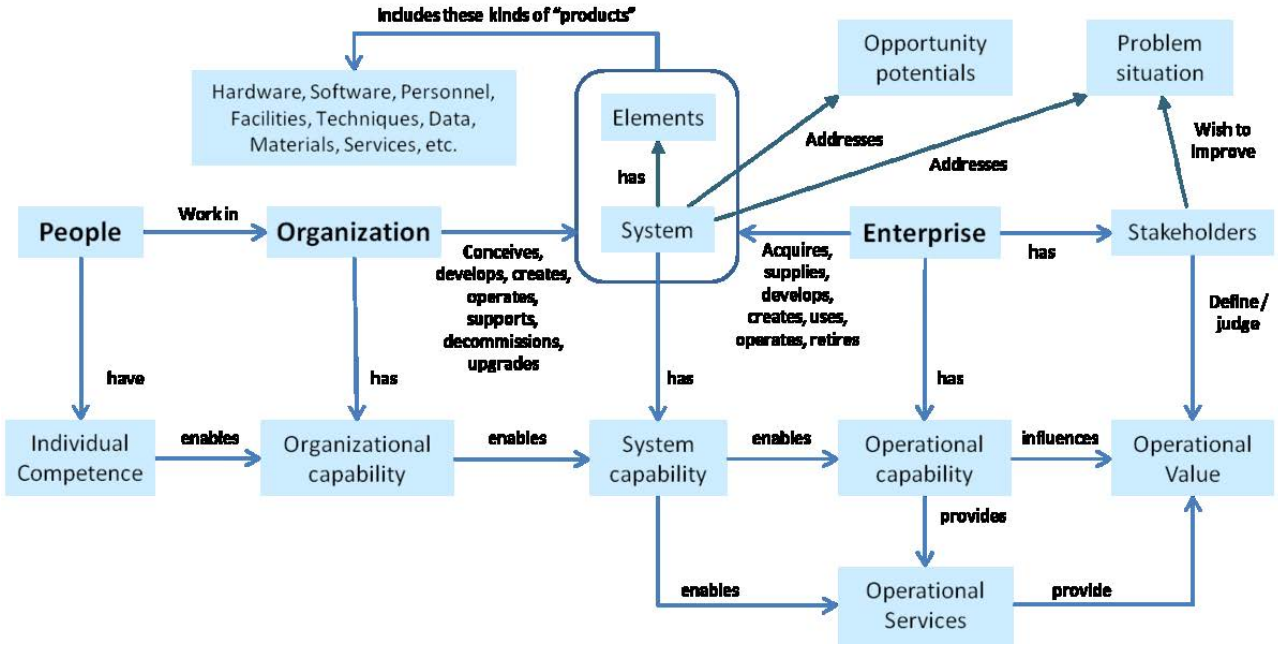

Figure 3. Organizational, System & Operational Capabilities. (SEBoK Original)

Technology and Standards Planning

The purpose of *Technology Planning* is to characterize technology trends in the commercial marketplace and the research community. This activity covers not just trend identification and analysis, but also technology development and transition of technology into programs and projects. It identifies current, and predicts future, technology readiness levels for the key technologies of interest. Using this information, it defines technology roadmaps. This activity helps establish the technical strategy and implementation guidance in the strategic technical plan. The business capabilities roadmap (BCRM) from the strategic planning activity is used to identify which technologies can contribute to achieved targeted levels of performance improvements.

The purpose of *Standards Planning* is to assess technical standards to determine how they inhibit or enhance the incorporation of new technologies into systems development projects. The future of key standards is forecast to determine where they are headed and the alignment of these new standards with the life cycles for the systems in the enterprise's current and projected future portfolios. The needs for new or updated standards are defined and resources are identified that can address these needs. Standardization activities that can support development of new or updated standards are identified (See also Systems Engineering Standards).

Enterprise Evaluation and Assessment

The purpose of enterprise evaluation and assessment (EE&A) is to determine if the enterprise is heading in the right direction. It does this by measuring progress towards realizing the enterprise vision. This process helps to "shape the environment" and to select among the program, project, and system opportunities. This is the primary means by which the technical dimensions of the enterprise are integrated into the business decisions.

This process establishes a measurement program as the means for collecting data for use in the evaluation and assessment of the enterprise. These measures help determine whether the strategy and its implementation are working as intended. Measures are projected into the future as the basis for determining discrepancies between what is observed and what had been predicted to occur. This process helps to identify risks and opportunities, diagnose problems, and prescribe appropriate actions. Sensitivity analysis is performed to determine the degree of robustness and agility of the enterprise.

Roberts states that EE&A must go beyond traditional system evaluation and assessment practices (Roberts 2006). He says that this process area:

> *must de-emphasize the utility of comparing detailed metrics against specific individual requirement values, whether the metrics are derived from measurement, simulation or estimation… [it] must instead look for break points where capabilities are either significantly enhanced or totally disabled.*

Key characteristics of this activity are the following:

- Multi-scale analysis,
- Early and continuous operational involvement,
- Lightweight command and control (C2) capability representations,
- Developmental versions available for assessment,
- Minimal infrastructure,
- Flexible modeling and simulation (M&S), operator-in-the-loop (OITL), and hardware-in-the-loop (HWIL) capabilities, and
- In-line, continuous performance monitoring and selective forensics. (Roberts 2006)

Enterprise architecture (EA) can be used as a primary tool in support of evaluation and assessment. EA can be used to provide a model to understand how the parts of the enterprise fit together (or do not) (Giachetti 2010). The structure and contents of the EA should be driven by the key business decisions (or, as shown in the six-step process presented by Martin (2005), the architecture should be driven by the "business questions" to be addressed by the architecture).

The evaluation and assessment success measures can be put into the EA models and views directly and mapped to the elements that are being measured. An example of this can be seen in the US National Oceanographic and Atmospheric Agency (NOAA) EA shown by Martin (2003a and 2003b). The measures are shown, in this example, as success factors, key performance indicators, and information needs in the business strategy layer of the architecture.

EA can be viewed as either the set of artifacts developed as "views" of the enterprise, or as a set of activities that create, use, and maintain these artifacts. The literature uses these terms in both senses and it is not always clear in each case which sense is intended.

Enterprise Portfolio Considerations

Opportunity Assessment and Management

The management activities dealing with opportunities (as opposed to just risk) are included in ESE. According to White (2006), the "greatest enterprise risk may be in not pursuing enterprise opportunities." Hillson believes there is:

> *a systemic weakness in risk management as undertaken on most projects. The standard risk process is limited to dealing only with uncertainties that might have negative impact (threats). This means that risk management as currently practiced is failing to address around half of the potential uncertainties—the ones with positive impact (opportunities).* (Hillson 2004)

White claims that "in systems engineering at an enterprise scale the focus should be on opportunity, and that enterprise risk should be viewed more as something that threatens the pursuit of enterprise opportunities" (White 2006). The figure below (Rebovich and White 2011, chapter 5) shows the relative importance of opportunity and risk at the different scales of an individual system, a system of systems (SoS), and an enterprise. The implication is that, at the enterprise level, there should be more focus on opportunity management than on risk management.

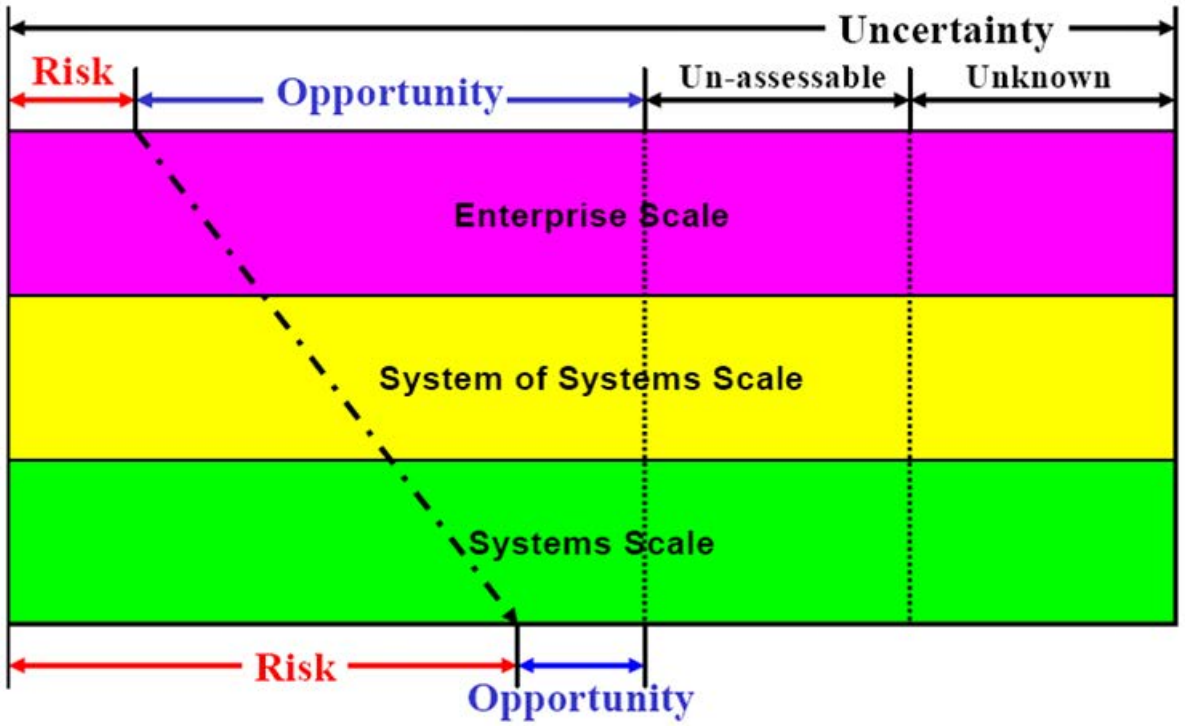

Figure 4. Risk & Opportunity at the Enterprise Scale versus the Systems Scale (White 2006). MITRE Approved for Public Release; Distribution Unlimited. Unique Tracking #05-1262.

Enterprise Architecture and Requirements

EA goes above and beyond the technical components of product systems to include additional items such as strategic goals and objectives, operators and users, organizations and other stakeholders, funding sources and methods, policies and practices, processes and procedures, facilities and platforms, infrastructure, and real estate. EA can be used to provide a model to understand how the parts of the enterprise fit together (or don't) (Giachetti 2010). The EA is not strictly the province of the chief information officer (CIO), and is not only concerned with information technology. Likewise, enterprise requirements need to focus on the cross-cutting measures necessary to ensure overall enterprise success. Some of these enterprise requirements will apply to product systems, but they may also apply to business processes, inter-organizational commitments, hiring practices, investment directions, and so on (Bernus, Nemes, and Schmidt 2003).

Architecture descriptions following the guidelines of an architecture framework have been used to standardize the views and models used in architecting efforts (Zachman 1987 and 1992; Spewak 1992). Architecture descriptions have also been developed using a business-question based approach (Martin 2003b; Martin 2006). The standard on Architecture Description Practices (ISO/IEC 42010) (ISO/IEC 2011) has expanded its scope to include requirements on architecture frameworks.

Government agencies have been increasingly turning to SE to solve some of their agency-level (i.e., enterprise) problems. This has sometimes led to the use of an architecture-based investment process, especially for information technology procurements. This approach imposes a requirement for linking business strategies to the development of EAs. The Federal Enterprise Architecture Framework (FEAF) (CIO Council 1999) and the DoD Architecture Framework (DoDAF) (DoD 2010) were developed to support such an architecture-based investment process. There have been several other architecture frameworks also developed for this purpose (ISO 2000; ISO/IEC 1998; NATO 2004; TOGAF 2009; MOD 2010; TRAK 2010).

ESE Process Elements

As a result of the synthesis outlined above, the ESE process elements to be used at the enterprise scale are as follows:

1. Strategic Technical Planning,
2. Capability-Based Planning Analysis,
3. Technology and Standards Planning,
4. Enterprise Evaluation and Assessment,
5. Opportunity and Risk Assessment and Management,
6. Enterprise Architecture and Conceptual Design,
7. Enterprise Requirements Definition and Management,
8. Program and Project Detailed Design and Implementation,
9. Program Integration and Interfaces,
10. Program Validation and Verification,
11. Portfolio and Program Deployment and Post Deployment, and
12. Portfolio and Program Life Cycle Support.

The first seven of these elements were described in some detail above. The others are more self-evident and are not discussed in this article.

Enterprise Capability Management

- Lead Authors:
- James Martin, Bud Lawson, and Alan Faisandier

-

Introduction

There are three different kinds of capability: organizational capability, system capability, and operational capability. Management of organizational capability is addressed in the article called Enabling Businesses and Enterprises. Management of system capability is addressed by the Systems Engineering (SE) management activities described in the articles called Technical Management Processes and Product and Service Life Management. Management of operational capability is described herein.

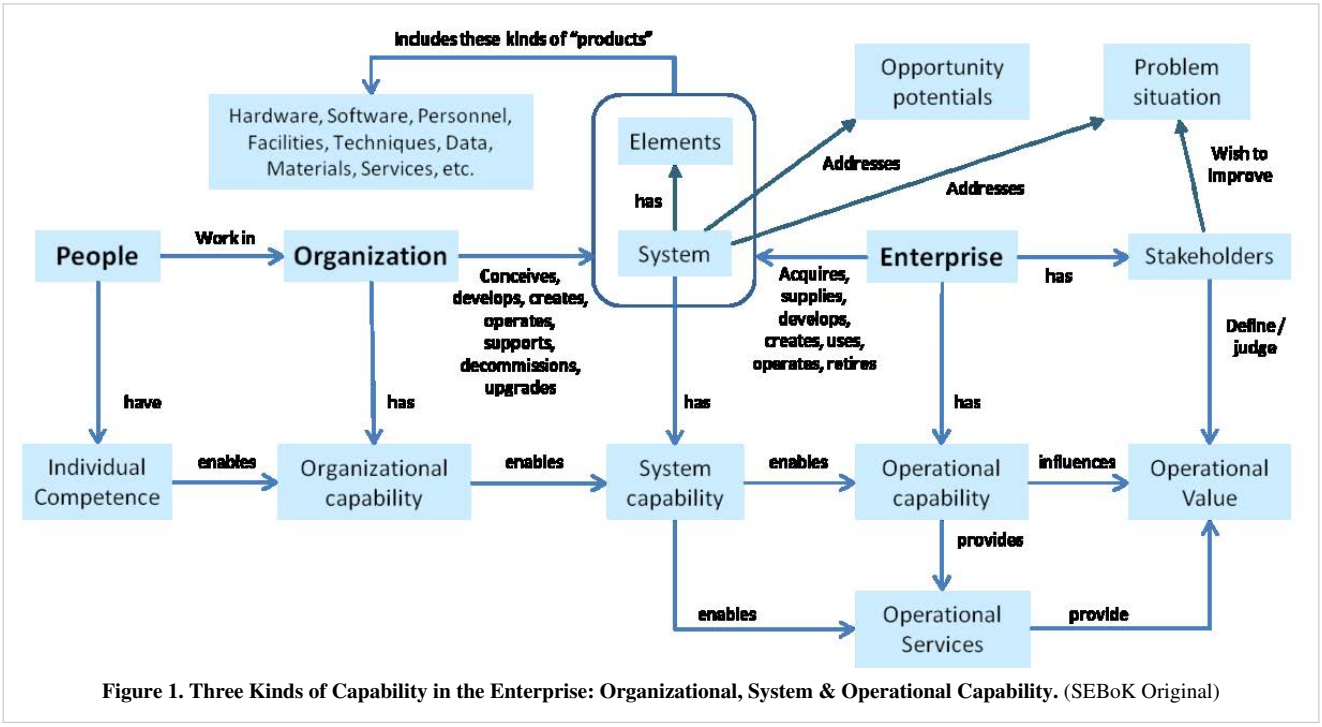

Figure 1. Three Kinds of Capability in the Enterprise: Organizational, System & Operational Capability. (SEBoK Original)

The enterprise has a current and planned (baseline) operational capability, based on its past activities and on its current plans for change. The purpose of the enterprise capability management function is to ensure the possibility of "vectoring" the enterprise away from the current baseline trajectory to a more desirable position where it can better meet its enterprise strategic goals and objectives, given all its resource constraints and other limitations.

Operational capability may need to include elements identified in the Information Technology Infrastructure Library (ITIL) best practices for operations management, starting with strategic operation planning (OGC 2009).

> *The ITIL is a set of practices for IT service management (ITSM) that focuses on aligning IT services with the needs of business. In its current form …, ITIL is published in a series of five core publications, each of which covers an ITSM lifecycle stage.*
>
> *ITIL describes procedures, tasks and checklists that are not organization-specific, used by an organization for establishing a minimum level of competency. It allows the organization to establish a baseline from which it can plan, implement, and measure. It is used to demonstrate compliance and to measure improvement.* (http:/ / en. wikipedia. org/ wiki/ Information_Technology_Infrastructure_Library).

Needs Identification & Assessment

The enterprise has key stakeholders that have operational needs they would like the enterprise to address. These operational needs must be identified and assessed in terms of their relevance to the enterprise and the relative priorities of these needs compared to each other and to the priorities of the enterprise itself. The enterprise exists to meet these needs. An operational need is an expression of something desirable in direct support of the enterprise's end user activities. End user activities include such things as retail sales, entertainment, food services, and business travel. An example of an operational need is: "Provide transportation services to commuters in the metropolitan area of London."

Enterprise needs can be much more than eliminating waste, and the challenge for ESE might relate to any or all of the following: countering a perceived threat (business or military), meeting a policy goal (as in government), doing existing business more efficiently, taking advantage of technological opportunities, meeting new operational needs, replacing obsolete systems, creating integrated enterprises with others (on a temporary or permanent basis), and so on.

In addition to operational needs, there are enterprise needs that relate to enabling assets the enterprise has in place that allow the mission to be accomplished. Enabling assets are things such as personnel, facilities, communication networks, computing facilities, policies and practices, tools and methods, funding and partnerships, equipment and supplies, and so on. An enterprise need is an expression of something desirable in direct support of the enterprise's internal activities. Internal activities include such things as market forecast, business development, product development, manufacturing, and service delivery.

The purpose of the enterprise's enabling assets is to effect state changes to relevant elements of the enterprise necessary to achieve targeted levels of performance. The enterprise "state" shown in the figure below is a complex web of past, current and future states (Rouse 2009). The enterprise work processes use these enabling assets to accomplish their work objectives in order to achieve the desired future states. Enterprise architecture (EA) can be used to model these states and the relative impact each enabling asset has on the desired state changes.

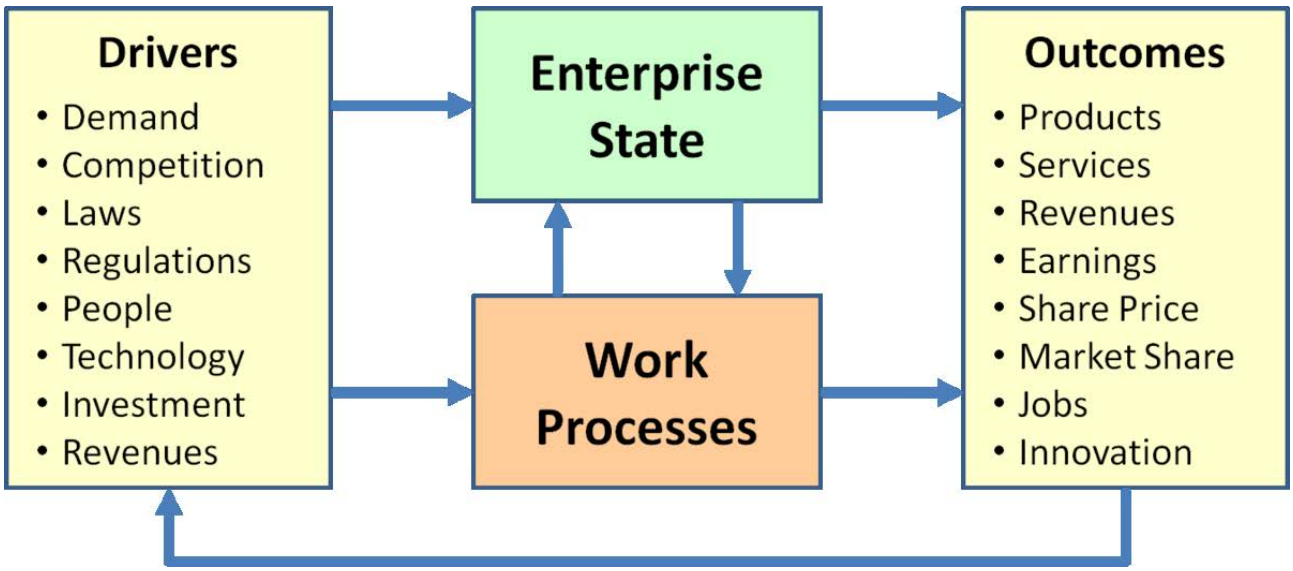

Figure 2. Enterprise State Changes Through Work Process Activities (Rouse 2009). Reprinted with permission of John Wiley & Sons Inc. All other rights are reserved by the copyright owner.

Enterprise needs are related to the enterprise efficiencies achieved through the performance of enterprise activities. The main goal of enterprise needs is to maximize the efficient utilization of enterprise assets, or in other words, enhance productivity, and find and eliminate waste. Waste represents that which does not contribute to the enterprise mission or that cannot reasonably be expected to be accomplished by the enterprise. An example of an enterprise need is: "Decrease power required for operation of enterprise data centers." (Power is a limited asset that consumes

scarce enterprise funds that could be used for delivery of other more valuable services to its customers.)

Capability Identification & Assessment

The capabilities of an enterprise should exist for the sole purpose of meeting mission and enterprise needs. Hence, there will be both mission and enterprise capabilities to identify and assess how well they meet these needs. An example of an operational capability is: "Transport 150,000 passengers per hour among 27 nodes in the network." A supporting enterprise capability might be: "Process 200,000 tickets per hour during peak loading." There is a baseline capability due to capability development up to that point in time, plus any additional capability planned for the future. The desired levels of capability (based on needs assessment) are compared to the baseline capability to determine the capability gaps for the enterprise. This activity will also determine points of excess capability.

The gaps should be filled and the excesses should be eliminated. The projected gaps and excesses are sometimes mapped into several future timeframes to get a better understanding of the relative timing and intensity of change that might be required. It is typical to use time "buckets" like near-term, mid-term, and far-term, which, for some long-lasting capabilities, might correspond to five, ten, and twenty years out respectively. Of course, for fast-changing capabilities (like consumer products) these timeframes would necessarily be shorter in duration, for example, one, two and three years out.

Enterprise Architecture Formulation & Assessment

Enterprise architecture analysis can be used to determine how best to fill these capability gaps and minimize the excess capabilities (or "capacities"). Usually a baseline architecture is characterized for the purpose of understanding what one currently has and where the enterprise is headed under the current business plans. The needs and gaps are used to determine where in the architecture elements need to be added, dropped, or changed. Each modification represents a potential benefit to various stakeholders, along with associated costs and risks for introducing that modification. Enterprise architecture can be used to provide a model to understand how the parts of the enterprise fit together (or do not) (Giachetti 2010).

The enterprise architecture effort supports the entire capability management activity with enterprise-wide views of strategy, priorities, plans, resources, activities, locations, facilities, products, services, and so on (ISO/IEC/IEEE 15288 (ISO/IEC/IEEE 2015) and architectural design process: ISO/IEC 42010 (ISO/IEC 2011) and ISO 15704 (ISO 2000)).

Opportunity Identification & Assessment

The enterprise architecture is used to help identify opportunities for improvement. Usually these opportunities require the investment of time, money, facilities, personnel, and so on. There might also be opportunities for "divestment," which could involve selling of assets, reducing capacity, canceling projects, and so on. Each opportunity can be assessed on its own merits, but usually these opportunities have dependencies and interfaces with other opportunities, with the current activities and operations of the enterprise, and with the enterprise's partners. Therefore, the opportunities may need to be assessed as a "portfolio," or, at least, as sets of related opportunities. Typically, a business case assessment is required for each opportunity or set of opportunities.

Enterprise Portfolio Management

If the set of opportunities is large or has complicated relationships, it may be necessary to employ portfolio management techniques. The portfolio elements could be bids, projects, products, services, technologies, intellectual property, etc., or any combination of these items. Examples of an enterprise portfolio captured in an architecture modeling tool can be found in Martin (2005), Martin et al. (2004), and Martin (2003). See Kaplan's work (2009) for more information on portfolio management, and ISO/IEC (2008) for information on projects portfolio management

process.

Enterprise Improvement Planning & Execution

The results of the opportunity assessment are compiled and laid out in an enterprise plan that considers all relevant factors, including system capabilities, organizational capabilities, funding constraints, legal commitments and obligations, partner arrangements, intellectual property ownership, personnel development and retention, and so on. The plan usually goes out to some long horizon, typically more than a decade, depending on the nature of the enterprise's business environment, technology volatility, market intensity, and so on. The enterprise plan needs to be in alignment with the enterprise's strategic goals and objectives and with leadership priorities.

The planned improvements are implemented across the enterprise and in parts of the extended enterprise (glossary) where appropriate, such as suppliers in the supply chain, distributors in the distribution chain, financiers in the investment arena, and so on. The planned changes should have associated performance targets and these metrics should be monitored to ensure that progress is being made against the plan and that the intended improvements are being implemented. As necessary, the plan is adjusted to account for unforeseen circumstances and outcomes. Performance management of enterprise personnel is a key element of the improvement efforts.

Enterprise Capability Change Management

In an operational context (particularly in defense) the term "capability management" is associated with developing and maintaining all aspects of the ability to conduct certain types of missions in a given threat environment. In an industrial context, capability refers to the ability to manage certain classes of product and service through those parts of their life cycle that are relevant to the business. Changes to enterprise capability should be carefully managed to ensure that current operations are not adversely affected (where possible) and that the long term viability of the enterprise is maintained. The following seven lenses can be used to facilitate change management: strategic objectives, stakeholders, processes, performance metrics, current state alignment, resources, and maturity assessment (Nightingale and Srinivasan 2011).

Capability management is becoming more often recognized as a key component of the business management tool suite:

> *Capability management aims to balance economy in meeting current operational requirements, with the sustainable use of current capabilities, and the development of future capabilities, to meet the sometimes competing strategic and current operational objectives of an enterprise. Accordingly, effective capability management assists organizations to better understand, and effectively integrate, re-align and apply the total enterprise ability or capacity to achieve strategic and current operational objectives; and develops and provides innovative solutions that focus on the holistic management of the defined array of interlinking functions and activities in the enterprise's strategic and current operational contexts.* (Saxena 2009, 1)

There is a widespread perception that capability management is only relevant to defense and aerospace domains. However, it is becoming more widely recognized as key to commercial and civil government efforts.

System of systems engineering (SoSE) is not a new discipline; however, this is an opportunity for the systems engineering community to define the complex systems of the twenty-first century (Jamshidi 2009). SoSE represents a challenge for system engineers, since it requires considerations beyond those usually associated with engineering to include socio-technical and sometimes socio-economic phenomena.

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs in turn are divided into topics. This KA on Systems of Systems contains the following topics:

- Architecting Approaches for Systems of Systems
- Systems Engineering for Systems of Systems
- Systems of Systems Analytic Approaches
- System of Systems and Complexity
- Socio-Technical Features of Systems of Systems
- Capability Engineering
- Mission Engineering

Characteristics and Definition of Systems of Systems

Maier (1998) postulated five key characteristics (not criteria) of SoS: operational independence of component systems, managerial independence of component systems, geographical distribution, emergent behavior, and evolutionary development processes, and identified operational independence and managerial independence as the two principal distinguishing characteristics for applying the term 'systems-of-systems.' A system that does not exhibit these two characteristics is not considered a system-of-systems regardless of the complexity or geographic distribution of its components.

In the Maier characterization, emergence is noted as a common characteristic of SoS particularly in SoS composed of multiple large existing systems, based on the challenge (in time and resources) of subjecting all possible logical threads across the myriad functions, capabilities, and data of the systems in an SoS. As introduced in the article

Emergence, there are risks associated with unexpected or unintended behavior resulting from combining systems that have individually complex behavior. These become serious in cases which safety, for example, is threatened through unintended interactions among the functions provided by multiple constituent systems in a SoS.

ISO/IEC/IEEE 21839 (ISO, 2019) provides a definition of SoS and constituent system:

> **System of Systems (SoS) —** *Set of systems or system elements that interact to provide a unique capability that none of the constituent systems can accomplish on its own. Note: Systems elements can be necessary to facilitate the interaction of the constituent systems in the system of systems*
>
> **Constituent Systems —** *Constituent systems can be part of one or more SoS. Note: Each constituent is a useful system by itself, having its own development, management goals and resources, but interacts within the SoS to provide the unique capability of the SoS.*

In addition, there are several definitions of system(s) of systems (SoS), some of which are dependent on the particularity of an application area (Jamshidi, 2005).

It should be noted that formation of a SoS is not necessarily a permanent phenomenon, but rather a matter of necessity for integrating and networking systems in a coordinated way for specific goals such as robustness, cost, efficiency, etc.

The US DoD (2008) defines Systems of Systems Engineering as "planning, analyzing, organizing, and integrating the capabilities of a mix of existing and new systems into an SoS capability greater than the sum of the capabilities of the constituent parts".

Because of the independence of the constituent systems, systems engineering processes are in most cases implemented for engineering both the constituent systems and the system of systems and need to be tailored to support the characteristics of SoS. These processes are shown in the table.

Table 1. Differences Between Systems and Systems of Systems as They Apply to Systems Engineering.

SE Process	Implementation as Applied to SoS
Agreement processes	Because there is often no top level SoS authority, the SoS often operate without explicit agreements and in some cases effective agreements among the systems in the SoS may be key to successful SoSE.
Organizational project enabling processes	When organizational processes exist, SoSE develops and maintains those for the SoS within the constraints of the system level processes.
Technical management processes	SoSE implements technical management processes applied to the particular considerations of SoS engineering - planning, analyzing, organizing, and integrating the capabilities of a mix of existing and new systems into a system-of-systems capability while systems continue to be responsible for technical management of their systems.
Technical processes	SoSE technical processes define the cross-cutting SoS capability, through SoS level business/mission analysis and stakeholder needs and requirements definition. SoS architecture and design frame the planning, organization and integration of the constituent systems, constrained by system architectures. Development, integration, verification, transition and validation are implemented by the systems. with SoSE monitoring and review. SoSE integration, verification, transition and validation applies when constituent systems are integrated into the SoS and performance is verified and validated.

Finally, based on work done by the INCOSE Systems of Systems Work Group (Dahmann, 2014), the major challenges facing SoSE have been catalogued in terms of seven pain points. These challenges are presented in the SoSE section of the INCOSE SE Handbook. (INCOSE 2023). These challenges include:

- **SoS Authorities**. In a SoS each constituent system has its own local 'owner' with its stakeholders, users, business processes and development approach. As a result, the type of organizational structure assumed for most traditional systems engineering under a single authority responsible for the entire system is absent from most SoS. In a SoS, SE relies on cross-cutting analysis and on composition and integration of constituent systems which, in

turn, depend on an agreed common purpose and motivation for these systems to work together towards collective objectives which may or may not coincide with those of the individual constituent systems.

- **Leadership**. Recognizing that the lack of common authorities and funding pose challenges for SoS, a related issue is the challenge of leadership in the multiple organizational environment of a SoS. This question of leadership is experienced where a lack of structured control normally present in SE of systems requires alternatives to provide coherence and direction, such as influence and incentives.
- **Constituent Systems' Perspectives.** Systems of systems are typically comprised, at least in part, of in-service systems, which were often developed for other purposes and are now being leveraged to meet a new or different application with new objectives. This is the basis for a major issue facing SoS SE; that is, how to technically address issues which arise from the fact that the systems identified for the SoS may be limited in the degree to which they can support the SoS. These limitations may affect the initial efforts at incorporating a system into a SoS, and systems 'commitments to other users may mean that they may not be compatible with the SoS over time. Further, because the systems were developed and operate in different situations, there is a risk that there could be a mismatch in understanding the services or data provided by one system to the SoS if the particular system's context differs from that of the SoS.
- **Capabilities and Requirements.** Traditionally (and ideally) the SE process begins with a clear, complete set of user requirements and provides a disciplined approach to develop a system to meet these requirements. Typically, SoS are comprised of multiple independent systems with their own requirements, working towards broader capability objectives. In the best case the SoS capability needs are met by the constituent systems as they meet their own local requirements. However, in many cases the SoS needs may not be consistent with the requirements for the constituent systems. In these cases, the SoS SE needs to identify alternative approaches to meeting those needs through changes to the constituent systems or additions of other systems to the SoS. In effect this is asking the systems to take on new requirements with the SoS acting as the 'user'.
- **Autonomy, Interdependencies and Emergence.** The independence of constituent systems in a SoS is the source of a number of technical issues facing SE of SoS. The fact that a constituent system may continue to change independently of the SoS, along with interdependencies between that constituent system and other constituent systems, add to the complexity of the SoS and further challenges SE at the SoS level. In particular, these dynamics can lead to unanticipated effects at the SoS level leading to unexpected or unpredictable behavior in a SoS even if the behavior of constituent systems is well understood.
- **Testing, Validation, and Learning.** The fact that SoS are typically composed of constituent systems which are independent of the SoS poses challenges in conducting end-to-end SoS testing as is typically done with systems. Firstly, unless there is a clear understanding of the SoS-level expectations and measures of these expectations, it can be very difficult to assess level of performance as the basis for determining areas which need attention, or to assure users of the capabilities and limitations of the SoS. Even when there is a clear understanding of SoS objectives and metrics, testing in a traditional sense can be difficult. Depending on the SoS context, there may not be funding or authority for SoS testing. Often the development cycles of the constituent systems are tied to the needs of their owners and original ongoing user base. With multiple constituent systems subject to asynchronous development cycles, finding ways to conduct traditional end-to-end testing across the SoS can be difficult if not impossible. In addition, many SoS are large and diverse making traditional full end-to-end testing with every change in a constituent system prohibitively costly. Often the only way to get a good measure of SoS performance is from data collected from actual operations or through estimates based on modeling, simulation and analysis. Nonetheless the SoS SE team needs to enable continuity of operation and performance of the SoS despite these challenges.
- **SoS Principles.** SoS is a relatively new area, with the result that there has been limited attention given to ways to extend systems thinking to the issues particular to SoS. Work is needed to identify and articulate the cross cutting principles that apply to SoS in general, and to developing working examples of the application of these principles. There is a major learning curve for the average systems engineer moving to a SoS environment, and a problem

with SoS knowledge transfer within or across organizations.

Types of SoS

In today's interconnected world, SoS occur in a broad range of circumstances. In those situations where the SoS is recognized and treated as a system in its right, an SoS can be described as one of four types (Maier, 1998; Dahmann and Baldwin, 2008, ISO 21839, 2019):

- **Directed** - The SoS is created and managed to fulfill specific purposes and the constituent systems are subordinated to the SoS. The component systems maintain an ability to operate independently; however, their normal operational mode is subordinated to the central managed purpose;
- **Acknowledged** - The SoS has recognized objectives, a designated manager, and resources for the SoS; however, the constituent systems retain their independent ownership, objectives, funding, and development and sustainment approaches. Changes in the systems are based on cooperative agreements between the SoS and the system;
- **Collaborative** - The component systems interact more or less voluntarily to fulfill agreed upon central purposes. The central players collectively decide how to provide or deny service, thereby providing some means of enforcing and maintaining standards; and
- **Virtual** - The SoS lacks a central management authority and a centrally agreed upon purpose for the SoS. Large-scale behavior emerges—and may be desirable—but this type of SoS must rely on relatively invisible mechanisms to maintain it.

This taxonomy is based on the degree of independence of constituents and it offers a framework for understanding SoS based on the origin of the SoS objectives and the relationships among the stakeholders for both the SoS and its constituent systems. In most actual cases, an SoS will reflect a combination of SoS types which may change over time. This taxonomy is in general use. It is presented in ISO 21841, "Taxonomy of Systems of systems". Other taxonomies may focus on nature/type of components, their heterogeneity, etc. (Cook, 2014)

As noted above, many SoS exist in an unrecognized state; this is increasingly true as the levels of interconnectivity between modern systems keeps increasing. Kemp et al (2013) describe such systems as “accidental” but they can be described as “discovered” (Dahmann and Henshaw, 2016) because it is only when they become significant for some reason that we recognize them, at which point they can usually fall into one of the above four categories, since their significance means they must now operate, with management, in some defined way.

From the SoSE point of view, another potential classification would consider the level of anticipation/preparation of SoSE with respect to SoS operations and level of stability of the SoS objectives; this is referred to as variability by Kinder et. al. (2012). This could range from an SoS which responds to a particular trigger and is put immediately in place when needs are expressed. An example of such an SoS would be a crisis management SoS. This type of SoS is updated dynamically during the operation. At the other end of the spectrum there are well-specified and stable SoS developed to answer to specified ongoing needs. An example of such a persistent SoS is an air traffic management system. This type of SoS is acquired and qualified in a well-defined environment and any need for evolution will imply a formal SE evolution and re-qualification.

While much of the early attention to SoS has focused on Acknowledged SoS where current SE practices can be adapted and applied, there is an increasing recognition that the predominance of SoS exist in the collaborative and virtual types (Honour 2016), and in those areas where SoS may not be officially recognized but affect many of the broader capabilities in today's interconnected world. In these cases, the focus is shifting to understanding SoS as socio-technical, complex adaptive systems rather than extensions of current technical systems with a focus on understand and addressing the inherent complexity of these types of SoS.

Scale and Scope of SoS

Earliest reference to systems of systems (Ackoff, 1971) described systems of systems as largely composed of organizations. As indicated above, SoS can range in scale and scope incorporating both technical systems as well as organizations, as shown in Figure 1.

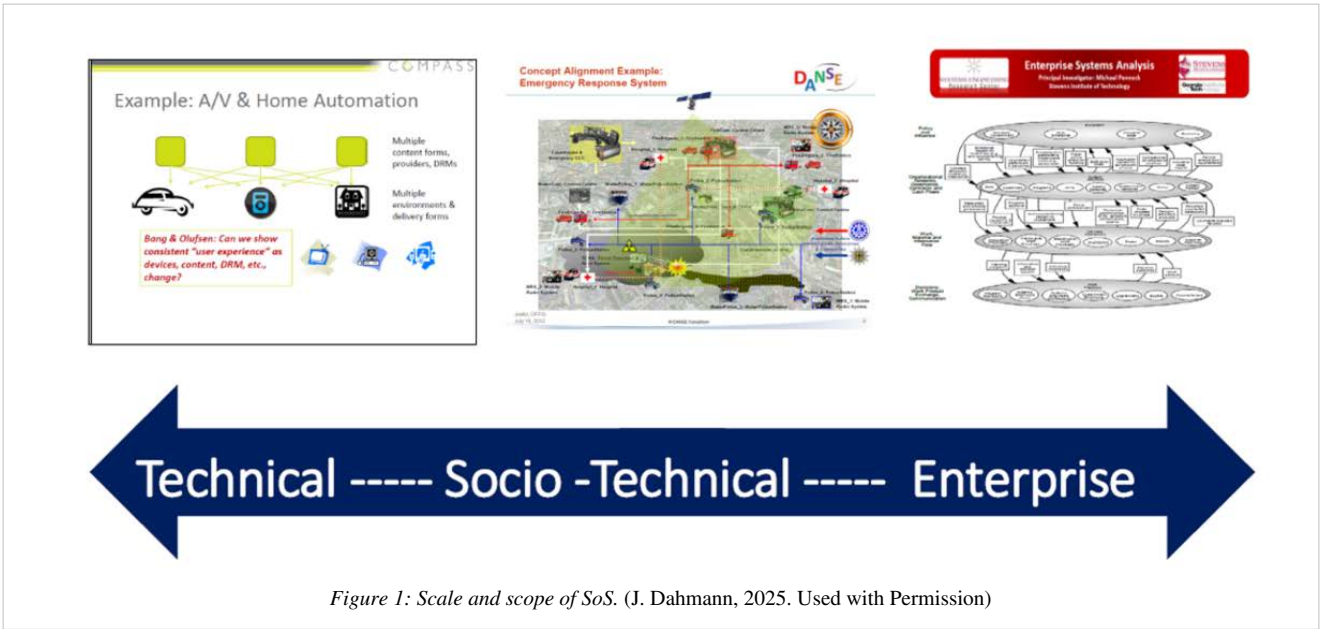

Figure 1: Scale and scope of SoS. (J. Dahmann, 2025. Used with Permission)

In some cases, SoS may focus almost entirely on technical integration with an example from an early European Commission (EC) research project COMPASS [Fitzgerald et al., 2012] which used as a case study in SoS the integration of the components of a consumer audio-visual 'system'. In other cases, there are socio-technical systems of systems where not only are the systems integral to the SoS capability but also the organizations and their processes. The figure shows the example of a disaster response SoS, a case example developed by the DANSE [Lochow, 2016] project. Finally, broader SoS address the scale and scope of enterprise level concerns. The example in the figure is the case of counterfeiting as an enterprise comprised of a wide variety of systems, organizations, policies, and competing efforts. [Bodner, 2015]

SoSE Application Domains

Application of SoSE is broad and is expanding into almost all walks of life. After initial attention in space systems (Krygiel,1980), SoSE was initially applied across defense. SoSE application is now much broader and still expanding. The early work in the defense sector has provided the initial basis for SoSE, including its intellectual foundation, technical approaches, and practical experience. In addition, parallel developments in information services and rail have helped to develop SoSE practice (Kemp and Daw, 2015). Now, SoSE concepts and principles apply across other governmental, civil and commercial domains.

A review of SoS IEEE publications on SoS from 2021-2023 [Dahmann, 2024] found that SoS is an area of global interest (see Table 2). Note that this analysis includes only references from IEEE publications and does not account for other published works (e.g. in INCOSE).

Table 2: Geographical distribution of authors of IEEE SoS papers from 2021-2023 [Dahmann, 2024, Used with Permission]

Top Countries	#	%	Top Regions	#	%
US	38	22.5%	Europe	77	45.6%
China	32	18.9%	US	38	22.2%
Germany	20	11.8%	Asia	38	22.2%
France	12	7.1%	Rest of the world	16	9.5%
Brazil	8	4.7%			
Netherlands	5	3.0%			
Italy	5	3.0%			
Australia	4	2.4%			
Countries with 1 or 2 authors	45	26.6%			

Tabler 3 shows the topics addressed In these papers, again showing the diverse application of systems of systems in the literature.Increased networking and interconnectedness of systems today contributes to growth in the number and domains where SoS are becoming the norm, particularly with the considerable converge among systems of systems, cyber-physical systems and the internet of things. (Henshaw, 2016).

Table 3: Topics Addressed in IEEE SoS papers from 2021-2023 [Dahmann, 2024, Used with Permission]

Application Areas	#	%
Defense	31	18.5%
Transportation	22	13.1%
Health	10	6.0%
IOT/CPS	8	4.8%
Energy	7	4.2%
Emergency/Crisis Management	6	3.6%
Space	4	2.4%
Search and Rescue	4	2.4%
Education	3	1.8%
Environment	3	1.8%
Remainder (<3)	70	41.7%

SoSE Standards

The first standards for system of systems engineering have been adopted by the International Standards organization. These were initiated in 2016 response to the report of an ISO SoS Standards study group (ISO, 2016) recognizing the increased attention to SoS and the value to standards to the maturation of SoSE. Three standards are (INCOSE 2020):

- ***System of Systems (SoS) Considerations in Life Cycle Stages of a System - ISO/IEC/IEEE 21839***

This standard provides a set of critical considerations to be addressed at key points in the life cycle of systems created by humans and refers to a constituent system that will interact in a system of systems as the system of interest (SOI). These considerations are aligned with ISO/IEC/IEEE 15288 and the ISO/IEC/IEEE 24748-1 framework for system life cycle stages and associated terminology.

- ***Guidelines for the utilization of ISO/IEC/IEEE 15288 in the context of System of Systems (SoS) Engineering - ISO/IEC/IEEE 21840***

This standard provides guidance for the utilization of ISO/IEC/IEEE 15288 in the context of SoS. While ISO/IEC/IEEE 15288 applies to systems (including constituent systems), this document provides guidance on application of these processes to SoS. However, ISO/IEC/IEEE 21840 is not a self-contained SoS replacement for ISO/IEC/IEEE 15288. This document is intended to be used in conjunction with ISO/IEC/IEEE 15288, ISO/IEC/IEEE 21839 and ISO/IEC/IEEE 21841 and is not intended to be used without them.

- ***Taxonomy of Systems of Systems - ISO/IEC/IEEE 21841***

The purpose of this standard is to define normalized taxonomies for systems of systems (SoS) to facilitate communications among stakeholders. It also briefly explains what a taxonomy is and how it applies to the SoS to aid in understanding and communication.

Architecting Approaches for Systems of Systems

- Lead Authors:
- Judith Dahmann and Mike Henshaw

-

Essentially, the role of the Systems Engineer with respect to system of systems SoS is to compose the constituent systems to meet the goals and needs of the SoS. In practice, this will largely require management of interfaces between constituent systems and leveraging the existing functionality of the constituent systems. However, it may also include changing the functionality of some constituent systems, the performance of interfaces, or the introduction of additional capability the purpose of which is solely to facilitate SoS operation.

Systems architectures and the process of architecting is covered by the ISO/IEC/IEEE 42000 series of standards and is overviewed by System Architecture Design Definition. In this article, we are concerned with the specific concerns related to architecting SoS.

ISO/IEC/IEEE 42010 (2022) defines architecting as 'conceiving, defining, expressing, documenting, communicating, certifying proper implementation of, maintaining and improving an architecture throughout the life cycle of an entity of interest'. For a SoS, the level of control varies according to its type; for a directed SoS, the owner, as architect, may be able to treat it as a monolithic system, whereas for a collaborative or virtual SoS, the architect may have little knowledge of many of the constituent systems. Furthermore, the notion of lifecycle is somewhat different because of the manner in which SoS evolve. Some may evolve over long periods of time and be reasonably stable, whereas others may be assembled transiently to achieve a specific purpose and then disassembled. The architectural approaches may need to be different accordingly.

(Wilkinson *et al.*, 2010) analyzed different belief systems in systems architecting and highlighted two important differences pertinent to the approach to architecting and the contrast between a monolithic system and a SoS. Firstly, they determined that whereas some architects through the purpose of architecting is to 'enable the building of better systems', i.e. a design approach which they termed *Forward Architecting*, others regarded its purpose as 'architecting is to understand existing parts of the environment as systems', referred to as *Reverse Architecting*. Secondly, they contrasted the view of Maier & Rectin (2009) of the purpose to be to deliver maximum value to the client (monolithic system) with MODAF (2008) that sought coherence across the capability of the SoS. MODAF, a contemporary architecture framework (now withdrawn) that has been described by Hause (2010).

The key themes for architecting SoS are interoperability and the management of interfaces, design for evolution and reconfiguration, and increasingly the role of MBSE and simulation within an architectural context.

The Role of System of Systems Architecting

In a SoS, the architecture is the technical framework for the systems comprising the SoS which designates how the systems will be employed by the users in an operational setting (sometimes called the concept of operations (CONOPs), the internal and external relationships and dependencies among the constituent systems and their functions and, finally, the end-to-end functionality and data flow as well as communications among the systems.

The management and/or operational independence of the constituent systems drive the special considerations for architecting a SoS. (Maier, 1998) has provided four principles for architecting SoS, motivated by these characteristics:

- The architect must pay attention to intermediate steps in a planned evolution of the SoS. This is realized in in the Wave Model [ref], which employs stable intermediate steps. This principle seems appropriate to the directed and acknowledged types of SoS, but is unlikely to be possible with the other types.
- Application of standards and protocols through, what Maier terms, policy triage. This recognizes that the opportunities to influence the constituent system design are limited and that the points of influence must be

chosen carefully.

- As noted above, architecting of SoS largely focuses on the interfaces, this means that the architect must leverage the interfaces to realize the capability that the SoS is assembled to deliver. Agreement on interface definition is essential and the use of standards and, in particular, Open Systems Standards, is a means through which competent composition and flexible evolution may be achieved. It is worth noting that the inclusion of COTS (Commercial Off-The- Shelf) systems within the SoS relies on compliance with standards both during configuration of the SoS and the design of constituent systems. COTS, and MOTS (Modified Off-The-Shelf) are frequently used to reduce cost and risk in systems development.
- Ensuring cooperation. Maier observes that collaboration between independent systems is only possible if the systems owners choose to collaborate. Thus, incentivizing collaboration, which requires an appreciation of motivations and non-technical aspects of assembly (such as commercial benefits and protection of IP) must be considered.

SoS are generally characterized by complexity and their assembly requires a mindset that thinks of design not as defined by an endpoint but by continual change and adaptation. The INCOSE Complexity Primer for Systems Engineers [INCOSE, 2021] articulates this well as 'Think like a gardener, not a watchmaker'. This is the mindset that the SoS architect must adopt.

Interoperability as a Key Feature of Architecting for SoS

Interoperability within a SoS implies that each system can interact with appropriate other members of the SoS to enable higher level functions unachievable by the single systems, regardless of their hardware and software characteristics or nature. This implies that each constituent member (and potential new members) of a SoS should be able to exchange data/information with others without compatibility issues in the operating systems, communication hardware, and so on. In general, interoperability focuses on data and information, although physical interoperability may sometimes be needed.

Data exchange patterns are comprised of three elements: an architectural pattern, a data format, a communication protocol (Charest *et al.*, 2020). There are many common languages for exchange of information and data, with XML (eXtensible Markup Language) being a popular choice.

However, interoperability must be achieved at many levels and not just at the data/network level. There are a number of frameworks that describe the levels of interoperability. From military applications, the NCOIC (Network Centric Operations Industry Consortium) Interoperability Framework (Osvalds, 2009) covers three broad levels of interoperability, subdivided into further layers as indicated below:

- Network Transport:
  - Physical Interoperability and
  - Connectivity and Network Interoperability;
- Information Services:
  - Data/Object Model Interoperability,
  - Semantic/Information Interoperability, and
  - Knowledge/Awareness of Actions Interoperability; and
- People, Processes and Applications:
  - Aligned Procedures,
  - Aligned Operations,
  - Harmonized Strategy/Doctrine, and
  - Political or Business Objectives.

This spectrum of interoperability layers requires appropriate coherence at each layer consistent with the SoS shared goals. Indeed, the vertical consideration of the framework is essential because, for example, agreement about the

data/object model interoperability level requires alignment of business objectives through collaborative or cooperative engagement.

There exist interoperability frameworks in other fields of activity. An example is the European Interoperability Framework (European Commission 2017), which focuses on enabling business (particularly e-business) interoperability and has six levels within a political context

- Interoperability Governance
- Integrated Public Service governance
- Legal Interoperability,
- Organizational Interoperability,
- Semantic Interoperability, and
- Technical Interoperability.

The interoperability between the component systems of a SoS is a fundamental design consideration for SoS that may be managed through the application of standards.

Challenges in Architecting SoS

It is rare that architecting a SoS can begin unencumbered by extant designs and legacy systems or infrastructure. In general, the SoS must be composed with extant constituent systems, perhaps designed to different standards and for different purposes. Moreover, the architect's knowledge of existing systems or those managed by alternative organizations, even competitors, is constrained. Thus, a mixed black-box, white-box approach to architecture definition may be needed. Even if the interfaces are well-defined, hidden functionality could potentially lead to undesirable emergent behavior.

The independence of the constituent systems means that these systems are typically designed to optimize system behavior, which may be at the expense of optimization for the SoS objectives. Indeed, it could be the case that the architect requires a constituent system to operate sub-optimally at the system level in order to achieve overall SoS effectiveness. (Rebovich 2009) has articulated this difficulty as a fundamental problem of SoS:

> *From the single-system community's perspective, its part of the SoS capability represents additional obligations, constraints and complexities. Rarely is participation in an (sic) SoS seen as a net gain from the viewpoint of single-system stakeholders.*

The development and implementation of a SoS architecture may be significantly constrained by a reluctance to make changes or invest in the constituent systems, which could be very mature (e.g. in sustainment) or currently productively supporting other uses. In this case, approaches such as gateways and wrapping may be used to incorporate these systems into the SoS without making significant changes in the other systems.

The co-simulation community seek to integrate different types of models within an overall framework, e.g. Gomes et al, 2018. This can be extended to consider models of different constituent systems using an MBSE approach. This has been demonstrated by (Dahmann *et al.*, 2017) in which a SoS architecture built with SysML includes executable models of the platforms, weapons, communications and data links.

(Maier, 1998) third principle, concerning leveraging the interfaces in SoS architecting and assembly is illustrated by (Shames, Sarrel and Friedenthal, 2016) using the example of a space data system. They highlight the role of standards in modelling the SoS interfaces using SysML defining the Interface Modelling Method that employs a black-box / white-box approach and the final step of which is to specify the standards that define interface compliance. The Object Management Group (OMG) are active in the development of standards to support interface design, as described by (Fosse and Delp, 2013).

Open Systems Architecture (OSA)

Open Systems Architectures is a particular approach to standards that seeks to enable commercial, technological, and operational agility (Henshaw *et al.*, 2011) by publishing standards enabling competition amongst suppliers and opportunities to rapidly deploy new systems (or sub-systems) within a SoS. It should be emphasized that Open Systems Architectures refers to an approach to the use of standards within acquisition and procurement, rather than to a particular class of architecture. Typically, government or tier 1 integrators may see benefits by enabling greater competition within the supply chain, and lower tier organisations may see benefits due to reduced barriers to entry. (Henshaw *et al.*, 2011) define an open architecture as: 'An Open (Systems) Architecture applies to a system in which the architecture is published in sufficient detail to enable change and subsequent evolution through the introduction or replacement of modules and/or components from any supplier', whereas the Defense Acquisition Glossary uses the definition: 'A technical architecture that adopts open standards supporting a modular, loosely coupled and highly cohesive system structure that includes publishing of key interfaces within the system and full design disclosure' [DAU, n.d.], whereas Radoman et al [2025] has provided a systemigram description of Open Systems Architecture, combining many different views and presenting an in depth analysis of benefits and actions to implement the approach.

OSA are used across several domains and, typically, open architecture standards are domain specific. Perhaps the broadest applicability is the MOSA (Modular Open Systems Approach), https:// www. cto. mil/ sea/ mosa that integrates business and technical strategy across the US DoD. Within the automotive industry, AUOTSAR, is an industry developed set of standards adopted by major automotive manufacturers as an effective supply chain management approach focusing on software. However, this might be regarded as an approach for complicated software-driven systems rather than SoS.

(Radoman *et al.*, 2023) has reviewed more than 80 open Architecture Standards in the military domain and provided a detailed database of her review.

Cook and Unewisse [2017] in “A SoS Approach for Engineering Capability Programs” outline the various approaches which have been adopted for SoSE. These are provided here using text drawn from this paper.

Enhanced Traditional Systems Engineering (ETSE)

ETSE applies traditional top-down systems engineering at the level of a portfolio of projects by adapting systems engineering processes and using architecture frameworks to represent the artifacts. Ideal for centralized, directed SoS management in a slowly changing environment. Key references: Levis and Wagenhals, (2000), USN, (2006 a&b).

Complex Systems Engineering (CSE)

CSE is based on complexity theory and strongly advocates that the top-down ETSE approach is not well suited to SoSE because it cannot handle the complexity of SoS and because the preconditions for TSE to be successful are not evident in SoS. CSE changes the focus from “…here is the solution designed from the requirements, now go implement it…” to “…here are the selective pressures acting on the elements present, now resolve or reduce them…” Ideal for rapidly integrating SoS from pre-existing Constituent Systems (CS) where little centralized control exists. Key reference: Bar-Yam, (2003); Norman and Kuras, (2006).

Dynamic Optimization of SOS using Value Measurement (DOSVM)

DOSVM draws on complexity theory and recognizes that it is the Constituent System Project Offices (CSPO) that have the resources and means to change, and that in many SoS, the actual authority and resources of any central element are never going to be sufficient to do more than guide the evolution of the SoS. In DOSVM, each CSPO views the SoS in terms of its utility to itself, seeking to “optimize” the SoS (from its point of view) through the influences available to it. DOSVM is ideal for collaborative SoS in which there is little or no central control. Key references: Honour (2016), Honour and Browning, (2007).

SoS Governance (SoSG)

SoSG, through its origins in complexity theory, seeks to expand SoSE away from the “technology first and technology only” perspective of earlier versions of SoSE. It includes appreciating the context to determine what initiatives might be feasible; identifying areas that can improve the SoS; and adopting a “long-term view” of the evolutionary development of the SoS. SoSG appreciates that de-centralized control can be expected and is suited to a wide range of collaborative and acknowledged SoS challenges. Key references: Keating (2015), Morris et al. (2006).

US Department of Defence SE for SoS: The Wave Model

The wave model is an evolutionary model that comprises five main process elements that incorporate experiential learning from many SoSE programs. It was originally designed for acknowledged SoS that have a small SoSE team but has also been applied to collaborative SoS challenges. It is a meta-methodology, i.e. one that guides the design of SoSE methodologies and is extensively documented. The wave model is widely applicable and is tailorable to the expected Australian Program level of SoSE effort. Key references: DoD, (2008), Dahmann et al (2011), Lane et al. (2010) & Dahmann and Heilmann (2012).

US Navy Mission Engineering Approach

Mission engineering arose to support the assessment of naval systems and capabilities through a SoS approach to analyze the impact of making naval investments across the diverse domains of surface, undersea, air, land, and networks as well as maritime coalition force integration. Mission engineering assessments are executed following a systematic, quantifiable, and iterative approach, which combines the structure of systems engineering (SE) and the tactical insights from operational planning. This approach incorporates a mission focus into integrated capability development. Note that mission engineering activities can be aligned to the elements of the wave model. Key references, Moreland (2015), TTCP (2016).

The British Systems Thinking Approach (BSTA)

BSTA embodies soft systems thinking, systems theory, social theory, and the pragmatism of problem solving to achieve shared meaning and objectives across the stakeholder group to deal with the social and technical aspects of SoS simultaneously. Key to the approach is the mapping of the SoS of interest onto more detailed SE approaches. The BSTA is the ideal approach for SoS problems where there is no obvious consensus of what represents a good SoS outcome trajectory and where the SoS is already established and running. It works well for a wide range of problem definition challenges within the CLC. It can be combined with other approaches. Key references: Checkland and Scholes (1990), Hitchins, (2007).

Systemic Strategic Planning and Execution (SSPE)

(SSPE) is a comprehensive but austere multi-methodology inspired firstly by strategic planning, systems theory and BSTA to achieve inclusivity and stakeholder engagement in a systemic way and secondly by ideas from system engineering to achieve structured abstraction and trade-offs between candidate force structures. SSPE is ideally suited to force design and has been used successfully in Australia; it needs to be enhanced with additional technical approaches to cover technical integration aspects. References: Hodge and Cook (2014a, b &c).

A Hybrid SoSE Approach Based on the Wave Model

This is an austere hybrid of the wave model with key elements from other approaches such as mission engineering. The wave model is inherently evolutionary and can be tailored to be agile, pragmatic, and austere and it is a proven approach that is well documented and has a track record of successful implementation, see, for example, Scrapper et al. (2016). Furthermore, for subsequent iterations, the wave model has the richness to support the technical aspects of integration, and the performance and behavioral analysis required for mission engineering. In addition, Dahmann (2012) has shown how the wave model can incorporate Program-level SoS test and evaluation. The proposed hybrid approach seeks to draw on the ability to design and manage enduring SoS capabilities across multiple defined development stages (as per the wave model) as well as the focus provided by considering the operational missions that instantiations of the SoS are to undertake thereby enabling assessment (as per mission engineering).

Systems of Systems Analytic Approaches

- Lead Authors:
- Mike Henshaw and Judith Dahmann

-

A review of SoS IEEE publications on SoS from 2021-2023 [Dahmann, 2024] looked across the SoS papers published in IEEE from 2020-2023 addressing a range of domains, incorporated several technical approaches including model-based approaches, graph analysis and artificial intelligence.

Model-based Approaches

First, as systems engineering moves towards becoming a model-based discipline, SoS engineering is part of this movement. Looking across the 138 domain focused papers in this review, the vast majority (120 or 90.9%) apply some type of model-based approach. These model-based approaches take different forms, including:

Network Models

These models represent the system of systems (SoS) as a network of interconnected nodes. They are used to analyze the robustness, resilience, and other properties of the system. Examples include the combat network model, network modeling of kill-web, and network model of a weapon technology system-of-systems.

Agent-Based Models

These models represent the SoS as a collection of agents, each with its own behavior. They are used to simulate the behavior of the system and evaluate policy changes. Examples include the agent-based modeling to represent the kidney transplant system of systems [Threlkeld, R et al. 2022].

Mathematical and Optimization Models

These models represent the SoS using mathematical equations or optimization problems. They are used to analyze and optimize the system's performance. Examples include the mixed-integer programming model for the combat system-of-systems architecture design problem and the mathematical model for the set covering problem.

Model-Based Systems Engineering (MBSE) and SysML

These tools are used to describe the structure and behavior of the SoS. They support activities like requirement analysis, design, verification, operation, and maintenance activities.

Simulation Models

These models are used to simulate the behavior of the SoS under different conditions. Examples include the simulation models to represent the kidney transplant system of systems [Threlkeld, R et al. 2022] and the digital real-time simulators.

Machine Learning Models

These models use machine learning algorithms to predict or classify outcomes based on input data. Examples include the use of machine learning algorithms to predict building maintenance and optimize energy use, and the use of a supervised learning model for classification and prediction of the failure status system.

Conceptual Models

These models represent the high-level structure and concepts of the SoS. Examples include the conceptual model for an interoperable and vendor-neutral communication framework for the agricultural domain and the conceptual model based on Hierarchical Systems (HS) technology.

Graph Analytic Approaches

By their nature networks of interconnected systems, SoS lend themselves to graph analytic approaches. From this set of SoS domain papers, 29 (of 132 or 22%) of the domain application papers employ graph analysis in some form. This includes:

Network Modeling

This includes modeling SoS architectures as single-layer or multilayer networks, using complex network methods for robustness assessment, and using network modeling and adjacency matrices to represent the kill-web.

Hypergraph Theory

This includes using hypergraphs to model the system of systems and represent the constraints between subsystems and utilizing hypergraph theory to manage the evolutionary development property in the complicated internal structure of SoS during physical faults.

Graph Theory

This includes applying graph theory and social network analysis to model communications, healthcare and other types of systems-of-systems.

Knowledge and Information Representation

This includes using graphical representations for the organizational modeling of the system of systems.

Dependency and Interconnection Analysis

This includes using Design Structure Matrices (DSM) for analyzing interdependencies of elements within a SoS.

Complex Network Analysis

This includes using complex network theory to Construction of a combat network based on the kill web, which can be represented as a graph with nodes and edges.

Artificial Intelligence Approaches

Finally, a quarter of these papers (36 out of 132, or 26%) applied artificial intelligence (AI) in their SoS analysis approach. The AI approaches used in these papers can be categorized as follows:

Machine Learning Algorithms

These include general machine learning techniques for fault detection and isolation, feature selection, and data processing. An example is the paper: "Federated Feature Selection for Cyber-Physical Systems of Systems" [P. Cassará et al. 2022].

Neural Networks and Deep Learning

This category includes applications to human-machine collaboration and swarm techniques for search and rescue operations with example papers: "A Robotic System of Systems for Human-Robot Collaboration in Search and Rescue Operations" [Chan T. H. et al. 2023] and "A Capability Fitting and Data Reconstruction Model Based on Particle Swarm Optimization-Bidirectional Deep Neural Network for Search and Rescue System of Systems" [Gao, Y. et al. 2023].

Genetic Algorithms

Genetic algorithms are used for mission planning, sensor allocation, and meta-architecture optimization. An example here is "A System of Systems for the Optimal Allocation of Pollutant Monitoring Sensors" [C. Carnevale. C. et al. 2022]

Artificial Intelligent Agents

The concept of Non-Human Knowledge Workers is introduced, which are artificial intelligent agents designed to relieve human knowledge workers of cognitive tasks in the one paper in this category: "A New Technology Rises Non-Human Knowledge Workers and Decision-Making in a System of Complex Systems" [Mortimore D. Et al, 2023]

Fuzzy Logic and Inference Systems

Fuzzy Inference Systems are used to assess the overall fitness measure of the System of Systems (SoS) and to calculate the overall fitness value in a genetic algorithm. An example here is "System of Systems Meta-Architecture Approach to Improve Legacy Metrorails for Enhanced Customer Experience" [Polley, M. et al. 2021].

AI in Autonomous Systems

The papers discuss the use of AI and machine learning in enhancing the level of autonomy in systems, including autonomous vehicles and offshore wind farms, as presented in "Symbiotic System of Systems Design for Safe and Resilient Autonomous Robotics in Offshore Wind Farms" [Mitchell, D. et al. 2021].

System of Systems and Complexity

- Lead Author:
- Judith Dahmann

-

Systems of Systems are generally characterized as complex (Sheard, 2019) (Luzeau et al.,2011) (Simpson, 2009) (DeLaurentis, 2007) (Ireland, 2014) (Magee, 2004), as is noted in the systems of systems (SoS) knowledge area of the SEBoK.

The question for those seeking to perform SoS Engineering (SoSE) then is how to address/use SoS complexity. Work has been performed in INCOSE to apply characterization of complexity to SoS. This work looks at how complexity affects SoS (Watson, 2020) and guiding principles to complexity thinking can be applied to SoSE (INCOSE, 2016).

Complexity Dimensions Applied to Systems of Systems

How and why are systems of systems (SoS) characterized by different dimensions of complexity? Drawing on the dimensions of complexity (Watson, 2019) it is clear that by their nature SoS are rich in complexity, as described below. For each complexity dimension, the dimension is defined and the characteristics of SoS which make them subject to this dimension are briefly presented. Diversity "encompasses the structural, behavior, and system state varieties that characterize a system and/or its environment." (Watson, 2019) By their nature, SoS are composed of independent systems. (Maier, 1998) (ISO, 2019) SoS can exhibit tremendous diversity across the constituent systems which provide a range of behaviors, functionality, and technical approaches. SoS are comprised of multiple independent systems with their own users, management structures, requirements etc. often developed prior to their membership in an SoS, increasing the likelihood of diversity among the constituents of a SoS.

Connectivity "characterizes connection of the system between its functions and the environment. This connectivity is characterized by the number of nodes, diversity of node types, number of links, and diversity in link characteristics." (Watson, 2019) SoS include connectivity within each constituent system, among SoS constituents

and between the SoS and its environment. Discontinuities (breaks in a pattern of connectivity at one or more layers) are often found in SoS. This links directly to dimensions of 'Interactivity' and 'disproportionate effects', since connectivity may lead to complex cascading interactions. Adaptability is defined as the characteristics of complex systems which "proactively and/or reactively change function, relationships, and behavior to balance changes in environment and application to achieve system goals." (Watson, 2019) SoS are composed of operationally independent systems [3]; hence the operators of each of system has their own rules of engagement and may react or adapt to changes in different ways based on their local objectives.

Multi-perspective refers to the fact that "multiple perspectives, some of which are orthogonal, are required to comprehend the complex system." (Watson, 2019) SoS are typically comprised of multiple independent systems which were developed and operated prior to the existence of the SoS; hence they each bring with them their own perspectives, which may or may not be aligned with the SoS. An understanding of the SoS considers all of these different perspectives. This links directly to the dimension of 'Multi-scale' since SoS may contain constituent systems of varying scales.

Complex system behavior "cannot be described fully as a response system. Complex system behavior includes nonlinearities. Optimizing system behavior cannot often be done focusing on properties solely within the system." (Watson, 2019) While the behaviors of the individual systems may be predictable, particularly when the numbers of systems are large and have multiple internal behaviors, SoS behavior can become unpredictable. Each constituent has been designed to be operated independently and safely within its own context. without regard to the potential impact on the behavior of itself, on other systems and on overall SoS behavior.

Dynamics in "complex systems may have equilibrium states or may have no equilibrium state. Complex system dynamics have multiple scales or loops. Complex systems can stay within the dynamical system or generate new system states or state transitions due to internal system changes, external environment changes, or both." (Watson, 2019) Following the discussion of behavior, these effects can be dynamic and impact other systems or have feedback loops leading to dynamic complexity. Notably, constituent systems may not only be managed independently, but they may also operate independently, increasing prospects of dynamic complexity.

Representations of "complex systems can be difficult to properly construct with any depth. It is often impossible to predict future configurations, structures, or behaviors of a complex system, given finite resources. Causal & influence networks create a challenge in developing 'requisite' conceptual models within these time and information resource constraints." (Watson, 2019) One feature of SoS is that boundary conditions can be hard to define, which includes not only which constituent systems are members of an SoS, but also which behaviors of a constituent system play a role in the SoS making representation of an SoS a challenge. Evolution is a dimension of complexity as "changes over time in complex system states and structures (physical and behavioral) can result from various causes. Complex system states and structures are likely to change as a result of interactions within the complex system, with the environment, or in application. A complex system can have disequilibrium (i.e., non-steady) states and continue to function." (Watson, 2019) Rarely do we 'develop and field' an SoS, rather SoS are typically composed of existing systems; changes in an SoS result from changes in one or more of the constituent systems (or in the environment), making SoS development an evolutionary process.

System emergence leading to unpredictable behavior is driven by unexpected emergence; "emergent properties of the holistic system unexpected (whether predictable or unpredictable) in the system functionality/response. Unpredictable given finite resources. Behavior not describable as a response system." (Watson, 2019) By definition, SoS are comprised of multiple independent systems. (Maier, 1998) (ISO, 2019). Changes in one system could lead to new behavior in another, leading to unpredictable results. Indeterminate boundaries result from the fact that "complex system boundaries are intricately woven with their environment and other interacting systems. Their boundaries can be non-deterministic. The boundary cannot be distinguished based solely on processes inside the system." (Watson, 2019) One feature of SoS is that boundary conditions can be hard to define, including which constituent systems should be included in representation of an SoS, and which behaviors of a constituent play a role

in the SoS.

Guiding Principles to Complexity Thinking Applied in Systems of Systems Engineering

The INCOSE Complexity Primer (INCOSE, 2016) outlines guiding principles to complexity thinking. As SoS exhibit complexity as discussed above, the next question is how these principles might then be applied to SoS.

Think like a gardener, not a watchmaker: "Consider the complexity of the environment and the solution and think about evolving a living solution to the problem rather than constructing a system from scratch." (INCOSE, 2016) SoS are often composed of current and new systems which support desired SoS capabilities and have evolved through interaction. Understanding these 'natural' interaction effects can be important in understanding the responses of constituent systems to various interventions.

Combine courage with humility: "It takes courage to acknowledge complexity, relinquish control, encourage variety, and explore unmapped territory. It takes humility to accept irreducible uncertainty, to be skeptical of existing knowledge, and to be open to learning from failure. A combination of courage and humility enables the complex systems engineer to risk genuine innovation and learn fast from iterative prototyping of solutions in context." (INCOSE, 2016) This principle aligns with the recognition in SoS, the SoS engineer is moving into new territory where there are large differences between the degree of control, the diversity of system technical and functional capabilities, and multiple overlapping authorities.

Take an adaptive stance: "Systems engineers should mimic how living systems cope with complexity by identifying and creating variation, selecting the best versions, and amplify the fit of the selected versions. This means, for example, to think "influence" and "intervention" rather than "control" and "design." (INCOSE, 2016) For most SoS, the successful SoS engineer recognizes that influence and intervention are the name of the game, since to a large extent control continues to rest with the constituents, and SoS architecture and design needs to accommodate the state of the constituent systems while addressing SoS capability objectives. Identify and use patterns: "Patterns are exhibited by complex systems, can be observed and understood, and are a key mechanism in the engineering of complex systems. Patterns are the primary means of dealing specifically with emergence and side effects—that is, the means of inducing desired emergence and side effects, and the means of avoiding undesired emergence and side effects." (INCOSE, 2016) Understanding systems, their behaviors and interactions is a core element of SoSE. By modeling these and treating them as opportunities, patterns can be an effective SoSE approach.

Zoom in and zoom out: Because complex systems cannot be understood at a single scale of analysis, systems engineers must develop the habit of looking at their project at many different scales, by iteratively zooming in and zooming out." (INCOSE, 2016) Effective SoSE is often called a 'middle out' process, where there is a need to understand the top-down drivers for the SoS, but also to respect the bottoms-up needs and capabilities of the constituents. Dynamics between these two perspectives reflects this 'zoom in and zoom out' principle in SoSE thinking.

Achieve Balance: "Optimization is often counterproductive within a complex system. Either the whole is sub-optimized when a part is optimized, or an optimized whole becomes rigid, unable to flex with changing conditions. Instead of optimizing, complex systems engineers should seek balance among competing tensions within the project. Systems engineers can leverage integrative thinking to generate improved solutions and avoid binary either/or tradeoffs." (INCOSE, 2016) In SoSE, if you are trying to 'optimize' you probably don't understand the situation. Multiple, often competing, objectives of the SoS and the constituents, requires options which continue to meet the constituent objectives but also address SoS capabilities. This links directly to both the 'Collaborate' and 'See through new eyes' principles.

Learn from problems: "In a changing context, with an evolving system, where elements are densely interconnected, problems and opportunities will continually emerge. Moreover, they will emerge in surprising ways, due to phase

transitions, cascading failures, fat tailed distributions, and black swan events." (INCOSE, 2016) SoS development is recognized as evolutionary (Maier, 1998). One life cycle approach, the SoS 'Wave Model' (Dahmann, 2011) explicitly sees each iteration of SoS evolution as starting with assessment of changes since the last wave, recognizing the importance of learning from problems and adapting.

Meta-cognition: "Meta-cognition, or reflecting on how one reflects, helps to identify bias, make useful patterns of thinking more frequent, and improve understanding of a complex situation." (INCOSE, 2016) One of the SoS pain points (Dahmann, 2010) is the need for "SoS Thinking' – a form of meta-cognition.

Focus on desired regions of outcome space rather than specifying detailed outcomes: "Instead of zeroing in on an exact solution, focus on what range of solutions will have the desired effects, and design to keep out of forbidden ranges." (INCOSE, 2016) It is important to define SoS needs in terms of broad capabilities (versus detailed solutions) since there are a larger number of factors to be considered in an SoS. In SoS terminology, the SoS 'requirements space' reflects this perspective.

Understand what motivates autonomous agents: "Changing rewards will shape collective behavior. Implement incentives that will move the system toward a more desired state." (INCOSE, 2016) A core element of SoSE (DoD, 2008) is to understand constituent systems and their relationships including the objectives and long-term goals for these systems. This provides the basis for assessing of changes systems will welcome, and potential for motivating constituents to provide needed SoS functionality and services aligned with their goals. This links directly to the "Use Free order' principle emphasizing value of promoting self-organization in complex systems.

Maintain adaptive feedback loops: "Adaptive systems correct for output variations via a feedback mechanism. Over time, feedback loops can either hit the limit of their control space or may be removed in the interest of maintaining stability. To maintain robustness, periodically revisit feedback and ensure that adaptation can still occur." (INCOSE, 2016) As noted above, under the SoS wave model (Dahmann, 2011) is constructed around this principle as applied to the SoS development and evolution life cycle. Integrate problems: "Focus on the relationships among problems rather than addressing each problem separately. This allows fewer solutions that take care of multiple problems in an integrative fashion." (INCOSE, 2016) In SoS methods (Cook, 2014) including the SoS Wave Model (Dahmann 2010) and the DoD SoS SE Guide, (DoD, 2008) there is an emphasis on understanding the full SoS context, enabling understanding connections, patterns, and opportunities for this type of integrated view.

Socio-Technical Features of Systems of Systems

- Lead Authors:
- Judith Dahmann, Mike Henshaw, and Bud Lawson
- Contributing Authors:
- Heidi Davidz and Alan Faisandier

-

In perhaps the earliest reference to Systems of Systems (SoS), Ackoff (1971) describes a concept that is mostly concerned with organizations, i.e. social. However, this section is concerned with the socio-technical aspects of technical SoS, which are composed of interdependent resources, such as, people, processes, information, and technology that interact with each other and with their environment in support of a common mission (glossary).

The Socio-Technical Nature of Systems of Systems

Rebovich (2009) [has captured the essence of the SoS problem as:

“From a single-system community’s perspective, its part of the SoS capability represents additional obligations, constraints and complexities. Rarely is participation in an (sic) SoS seen as a net gain from the viewpoint of single-system stakeholders.”

Three of the persistent SoS challenges, or pain points, identified by Dahmann (2015) are directly related to this problem of stakeholder perspective and the local optimization of constituent system performance at the expense, or to the detriment of, the overall SoS performance. These are: SoS Authority, Leadership, and Autonomy, Interdependencies & Emergence. Thus, the sociological aspects affecting decision making and human behaviors must be given similar weight to the technical aspects of SoS.

Turning to views outside of Systems Engineering, Ergonomists regard socio-technical systems as having the following characteristics (Maguire, 2014):

- There are collective operational tasks,
- They contain social and technical sub-systems,
- They are open systems (i.e. strongly interacting with their environments), and
- The concept of the system being an unfinished system.

These are also characteristics of Systems of Systems. Klein (2014) has noted that approaches to socio-technical systems can take the two perspectives of “system affects people” or “people affect system”, depending upon how the system boundary is drawn. It is generally true for systems that consideration of their context requires socio-technical aspects to be taken into account.

Although focused largely on IT systems, Baxter and Sommerville (2011) have noted that the introduction of new business SoS are generally carried out in conjunction with a change process. They argue that frequently the social and organizational aspects are disruptive and that inadequate attention is paid to the connection between change processes and systems development processes. They propose two types of Socio-Technical Systems Engineering activities:

- Sensitizing and awareness activities, designed to sensitize stakeholders to the concerns of other stakeholders.
- Constructive engagement activities, which are largely concerned with deriving requirements accurately and meaningfully.

The extent to which these activities can be effective may be challenged by independent management or operation of constituent systems in a SoS.

Although there are many matters concerning the socio-technical aspects of SoS, there are two important issues, that are dealt with her. The first is the need for appropriate governance structures, given that operational and/or

managerial independence affects top-down direction of the SoS and may compromise achievement of the SoS goal(s). The second issue is a lack of situational awareness of managers, operators, or other stakeholders of the SoS, so that they may not understand the impact of their local decisions on the wider SoS.

SoS Governance

Generally, design and operation of complex systems is concerned with control, but the classification of SoS (Dahmann, et. al., 2008) is based on the notion of diminishing central control, as the types go from directed to virtual. Sauser, et. al. (2009) has described the 'control paradox of SoS' and asserted that for SoS, 'management' is replaced by 'governance'. 'Control is a function of rules, time, and bandwidth; whereas command is a function of trusts, influence, fidelity, and agility'.

Some practitioners have found the Cynefin framework, developed by David Snowden, helpful in understanding the nature of complexity that may arise in SoS. Developed from knowledge management considerations, Kurtz and Snowden (2003) propose three reasons why the behavior of systems involving people may be difficult to predict. Firstly, humans are not limited to one identity, and so modelling human behaviors using norms may not be reliable. Secondly, humans are not limited to acting in accordance with predetermined rules. Thirdly, humans are not limited to acting on local patterns. These reasons all undermine control, so that the sociological aspects of SoS make their behaviours hard to predict and, possibly indeterminate. The Cynefin framework considers systems to be classified in four domains:

- Known – simple systems with predictable and repeatable cause and effect
- Knowable – amenable to systems thinking and analytical/reductionist methods
- Complex – adaptive systems where cause and effect are only discernable in retrospect and do not repeat
- Chaotic – no cause and effect relationships are perceivable

The different types of SoS (directed, acknowledged, collaborative, and virtual) could all be described in any of the above domains, depending on many factors internal to the SoS, but in all cases it is the sociological element of the socio-technical SoS that is most likely to give rise to ambiguity in predicting behavior.

A major governance issue for SoS is understanding the ownership of, and making reliable estimates of risk (Fovino & Masera, 2007). High levels of connectivity, and the potential for emergent behavior due to the interactions of separately owned/operated constituent systems, means that significant risks may go unacknowledged and their mitigations unplanned.

In general, governance can be summed up by asking three connected questions (Siemieniuch and Sinclair, 2014):

- Are we doing the right things (leadership)?
- Are we doing those things right (management)?
- How do we know this (metrics and measurements)?

Currently, there is no accepted framework for addressing these questions in a SoS context, but Henshaw et. al. (2013) highlighted architectures as an important means through which governance may be clarified. They postulate that a SoS can be regarded as a set of trust and contract relationships between systems (i.e. including both informal and formal relationships). The systems architect of a constituent system must, therefore, address trust issues for each participating organization in the overall enterprise with which his/her system must interoperate. For SoS, technical engineering governance is concerned with defining and ensuring compliance with trust at the interface between constituent systems. An example of difficulty managing the interfaces in a SoS is provided in the Cassini-Huygens mission case study .

Situational Awareness

Situational awareness is a decision maker's understanding of the environment in which he/she takes a decision; it concerns information, awareness, perception, and cognition. Endsley (1995) emphasizes that situational awareness is a state of knowledge. There are numerous examples of SoS failure due to the operator of one constituent system making decisions based on inadequate knowledge of the overall SoS (big picture).

On the other hand, SoS development is also viewed as the means through which improved situational awareness may be achieved (Van der Laar, et. al., 2013). In the defense environment, Network Enabled Capability (NEC) was a system of systems approach motivated by the objective of making better use of information sharing to achieve military objectives. NEC was predicated on the ability to share useful information effectively among the stakeholders that need it. It is concluded that improving situational awareness will improve SoS performance, or at least reduce the risk of failures at the SoS level. Thus, the principles which govern the organization of the SoS should support sharing information effectively across the network; in essence, ensuring that every level of the interoperability spectrum is adequately serviced. Operators need insight into the effect that their own local decisions may have on the changing SoS or environment; similarly they need to understand how external changes will affect the systems that they own.

Increasingly, SoS include constituent systems with high levels of autonomous decision making ability, a class of system that can be described as cyber-physical systems (of systems). The relationship to SoS is described by Henshaw (2016). Issues arise because autonomy can degrade human situational awareness regarding the behavior of the SoS, and also the autonomous systems within the SoS have inadequate situational awareness due to a lack of competent models of humans (Sowe, 2016)

Capability Engineering

- Lead Authors:
- Duncan Kemp, Judith Dahmann, and Mike Henshaw

-

Capability has been used to describe the Systems Engineering of Operational Capabilities. The INCOSE UK Capability System Engineering Guide (Kemp and Daw) built on this analysis and describes:

- That Capabilities are realized through a combination of people, processes, information as well as equipment;
- They are concerned with delivering outcomes, rather than outputs;
- They are enduring, with capabilities being upgraded rather than replaced;The term emerged in defense in the early 2000s; however, the concepts go back far earlier (Checkland, 1997).
- The concepts of Capability Systems Engineering have been used in Rail (Dogan, 2012) and Healthcare (Royal Academy of Engineering, 2017).

Capability is widely used across many industrial sectors and has begun to take on various specific meanings across, and even within, those sectors. Terms such as capability-based acquisition, capability engineering and management, life capability management, capability sponsor, etc. are now ubiquitous in defense and elsewhere. Henshaw et al. (2011) have identified at least eight worldviews of capability and capability engineering and concluded that the task of capability engineering is not consistently defined across the different communities.

The aim of capability systems engineering is to ensure that the upgraded capability meets stakeholders needs. Good Capability Systems Engineering provides a clear line of sight from the purpose of the capability, through the operational concept and whole system design down to specific requirements and interfaces.

Capability engineering is concerned with the whole lifecycle; the “Fuzzy front end” of capability trade-offs, the conventional ‘V’ product lifecycle, and the “Messy in-service” support phase.

Capability Systems Engineering uses standard SE tools, applied from the perspective of the asset owner-operators (i.e. the military user or rail transportation provider).

Kemp and Daw (2014) note several differences between Capability Systems Engineering and the more traditional product Systems Engineering:

- Using persuasion and influence as much as command and control to implement decisions
- Building in flexibility where possible, as the capability will change.
- Implementing the transition to the improved capability as both an engineering and cultural change.
- Recognizing that capabilities are often Complex Adaptive Systems. As the capability improves, users or competitors change their behavior, reducing the effectiveness of the capability.
- Capability trade-offs are not about simple comparisons, between similar things – often they are choices between new equipment, better training, or new processes.

There is a strong relationship between Capability Engineering and system of systems (SoS). To some a Capability is a type of system/SoS, to others it is what the system/SoS does. This is explored in Henshaw et al. (2011), who describe at least eight worldviews of capability and capability engineering

Mission Engineering

- Lead Author:
- Judith Dahmann
- Contributing Authors:
- Ron Giachetti, Andy Hernandez, and Rhys Kissell

-

This article describes mission engineering, especially as defined by the United States Department of Defense (US DoD). The article defines mission engineering and describes the systems engineering activities involved in mission engineering.

Definition of Mission Engineering

Mission engineering is an interdisciplinary process encompassing the entire technical effort to analyze, design, and integrate current and emerging operational needs and capabilities to achieve desired mission outcomes. In mission engineering, the mission itself becomes a system of interest. The US DoD's Mission Engineering Guide (2023) states:

> The mission engineering process decomposes missions into constituent parts to explore and assess relationships and impacts in executing the end-to-end mission.

System engineering focuses on designing systems (including SoS) to achieve specified technical performance metrics. Mission engineering goes one step further to evaluate the performance of the SoS in achieving the mission or capability objectives when implemented in a simulated realistic scenario. Mission engineering evaluates whether the SoS achieves the expected or desired effects and determines whether those effects contribute to mission success.

Goal of Mission Engineering

The goal of mission engineering is to engineer missions by identifying the right things (i.e., technologies, systems, SoS, or processes) to achieve the intended mission outcomes and provide mission-based inputs into the systems engineering process to aid the Department in building things right. [US DoD, 2023)

The US DoD developed the first guidance on mission engineering, and there is a growing body of practice in mission engineering competencies, education and methods (Hutchison et al., 2018) (Von Bossuyt et al, 2019) (Beam, 2015). Zimmerman and Dahmann (2018) reviewed the challenges that face mission engineering and presented the case for the use of digital engineering to support mission engineering, as well as the engineering of systems, which was the initial focus of the US DoD Digital Engineering Strategy (Dahmann, 2019). Use of systems modelling language (SysML) to develop mission architecture models that support mission engineering practices is now considered good practice (Dahmann and Parasidis, 2024).

Key Concepts in Mission Engineering

Key concepts in mission engineering are:

Mission: The "task, together with the purpose, that clearly indicates the action to be taken and the reason thereby. More simply, a mission is a duty assigned to an individual or unit" [US DoD. 2011].

Mission Thread (MT): The "activities of a given mission approach" [US DOD, 2023]

Mission Engineering Thread (MET): "How the mission activities related to the actors, systems, and organizations are executed in a specific mission context" [US DOD, 2023]. METs are equivalent in concept to kill chains or effects chains but are formalized representations of mission execution, used to model system and actor interactions in a specific operational context.

Mission Architecture: "An interwoven effects web, or kill web, comprised of many mission threads and mission engineering threads" [US DoD, 2023]

Implementing Mission Engineering

The US DoD Mission Engineering Guidebook 2.0 lays out a methodology for implementing mission engineering as shown below.

Mission Engineering Methodology from the DoD MEG 2.0 (US DoD,2023)

The key activities in implementing mission engineering are (Dahmann and Parasidis, 2024]:

Mission Problem Definition: ME starts with defining and understanding the problem to be addressed, which drives the focus and scope of the ME and analysis activity. ME problems may be based on a proactive interest in the mission outcomes of a priority or pressing scenario, a reaction to a perceived problem in mission results or by an interest in the potential for a new or emerging technology or new operational concept to impact the success of the mission.

Mission Characterization: Mission characterization is a description of the operational mission context for the problem of interest including factors such as the epoch, physical environment, threat, blue force mission objectives, force laydown and CONOPs, as well as the objectives of the mission, which are the measure of mission outcomes.

Mission Architecture: Data extracted from mission characterization drives a model of baseline architecture including the baseline MT and METs. This is used as the blueprint for operational analysis of the impact of the baseline architecture on mission outcomes. Once the baseline operational analysis is complete and gaps in mission outcomes have been identified, the mission architecture models are updated to incorporate alternative approaches and concepts to be considered in the analysis.

Mission Engineering Analysis: The mission impact of the baseline architecture is analyzed in an appropriate analysis environment, typically an operational analysis simulation to assess the mission outcomes of the baseline in the selected scenario and vignette. The analysis is then run with the changes that represent the selected alternative concepts or capabilities to assess the mission impact of the alternative architectures.

Results and Recommendations: Using the results of the ME analysis, comparing the baseline mission outcomes with the incorporated outcomes of alternative concepts, provides the base for results and recommendations.

As stated in the DoD ME Guidebook," [t]he results of mission engineering are used for a variety of purposes. For instance, findings can inform technology investments, suggest alternative ways to use current systems, identify mission gaps and preferred approaches to addressing these gaps, and trigger the initiation of a new acquisition to meet capability gaps." [US DoD, 2023].

Mission engineering continues to evolve as a critical capability within defense systems development, enabling the integration of complex capabilities around mission outcomes rather than isolated system performance with potential application beyond defense.

Knowledge Area: Healthcare Systems Engineering

Healthcare Systems Engineering

Contents of this Knowledge Area

- Overview of the Healthcare Sector (Chris Unger) (Cyrus Hillsman)
- Systems Engineering in Healthcare Delivery (Cyrus Hillsman) (Chris Unger and Nicole Hutchison)
- Systems Biology (Bridgette Daniel Allegro and Gary Smith) (Chris Unger and Nicole Hutchison)
- Lean in Healthcare (Bohdan Oppenheim) (Chris Unger and Nicole Hutchison)

-

This article provides an overview of the role of systems engineering in the engineering or re-engineering of healthcare systems to meet a number of modern day challenges. The role of SE in medical devices, healthcare IT, pharmaceuticals, and public health systems are considered and contrasted to "traditional" SE practices discussed elsewhere in the SEBoK. See Overview of the Healthcare Sector for details of the stakeholders and constraints of the these different parts of the sector.

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs in turn are divided into topics. This KA contains the following topics:

- Overview of the Healthcare Sector
- Systems Engineering in Healthcare Delivery
- Systems Biology
- Lean in Healthcare

Healthcare and Systems Engineering

Healthcare today faces many challenges related to safety (e.g. Hospital Safety Score 2013, Andel et al. 2012, Institute of Medicine 1999), affordability, access, and the means for reliably producing positive outcomes for all patients of all ages and across all care environments. Furthermore, the health of individuals is challenged by many threats such as environmental and behavioral norms, emerging natural infectious diseases, and acute and chronic conditions that are becoming more prevalent because of longer lifespans. Re-engineering today's healthcare to address these challenges requires a systems approach – an approach that develops solutions to contend with the complexity of healthcare-related policy, economics, social dynamics, and technology. Systems Engineers are trained to grapple with this kind of complexity by thinking holistically and to work with trans-disciplinary teams to develop solutions making re-engineering healthcare a natural fit for systems engineers and the tools of systems engineering.

The disciplines involved in re-engineering healthcare are far reaching across academia, government, industry, private, and public sectors including the patients and families the healthcare field serves. Systems Engineers involved in this re-engineering draw on several tools when working with these stakeholders to develop solutions. In doing so they follow the general systems principles described in the Systems Approach Applied to Engineered Systems knowledge area in SEBoK Part 2. First, with so many diverse stakeholders involved in this field, it is vitally important for the Systems Engineer to help clarify the problem or opportunity and to conceive of the objective of the

re-engineering. They need to "envision the solution" without being entirely prescriptive of the solution's specific implementation, see Identifying and Understanding Problems and Opportunities. Then, drawing from best practices, the Systems Engineer guides the stakeholders through the synthesis of possible solutions and the analysis and selection between alternatives. Systems engineers are also involved in the implementation and testing and the deployment, use and sustainment of healthcare systems to provide stakeholder value. The systems approach in healthcare must be particularly mindful to not exclusively focused on technical aspects of the effort since the solutions to healthcare's challenges exist not only in technical areas but the integration of culture, workflow and processes, with technology as a tool to support the delivery of safe, affordable, and accessible care.

To achieve this system approach healthcare projects follow a version of the SE life cycle described in SEBoK Part 3. This included the creation of Stakeholder and System Requirements, Systems Architecture and Design and System Integration, Verification and Validation. The SE life cycle extends to include System Deployment, Operation, Maintenance and Logistics. Healthcare project will also follow some of the Technical Management Processes processes described in Part 3.

It is vitally important for the healthcare systems engineer to ensure socio-technical integration and interoperability among system components are part of any project – the last thing healthcare needs is another standalone innovation that perpetuates the silos that exist in the field today. Remaining focused on the objective and problem to solve, managing scope creep, disciplined design, implementation, and project management are key activities the Systems Engineer is responsible for in healthcare systems engineering.

Systems Engineering for Medical Device Development

Systems Engineering for medical device development is essentially an application of Product Systems Engineering as described in SEBoK Part 4 with a few customizations:

- The life cycle has to comply with specific healthcare regulations, which constrain aspects of the life cycle, as exemplified by FDA regulations in the US (21CFR 820.30)
- The products are market driven, with little customization allowed by the manufacturer at the customer site
- The markets are midsized, with the market for a given technology or product line often being in the $1-10B range
- Medical device development programs are mid-sized…many from 10-100 man-years of development, lasting 1-2 years
- Time to market is critical, with the first mover or first with a complete solution capturing the majority of the profits
- Most products are cyber-physical, with software becoming a larger part of the product. Many products include significant aspects of physiology or chemistry
- There is a special tension between "efficacy" and "safety". Efficacy requires the vast majority to be helped. Safety is compromised if only a very small minority is adversely affected. Truly safe systems require a special approach to systems engineering . (Leveson 2011)
- Customer feedback may be constrained by safety issues as well as HIPAA regulations

Device Development in a Market Environment

One critical difference between many "traditional" systems engineering industries (defense and aerospace) and healthcare device development is that most healthcare device development is market driven, rather than contract driven. Some key differences between market and contract systems engineering:

- The program size (budget) and dates are not 'fixed', they are set by the business leadership designed to maximize return on investment across a portfolio of product programs
- Program scope and requirements are not fixed externally; they can be changed fairly rapidly by negotiation between functions and the executive committee.

- The goal for the product development isn't necessarily a feature set, it is a market share and price premium relative to the competition…which can be a moving target. A competitive announcement will often force a change in the program scope
- In a contract based program there is an identified customer, with a set of applications and workflows. In a market driven program the workflow and use cases are defined by the developer, and the buyer needs to 'own' the integration of the offering into their specific systems and workflows.
- For specific medical products the FDA can require pre-market trials and post market studies . (FDA 2014)
- The different types of healthcare reimbursement across the world (universal coverage private insurance, national single provider, national single payer, private insurance, and out of pocket) creates dramatically different market dynamics (for individuals, healthcare providers, and product developers) . (Reid 2010)

Regulations for Medical Device Development

As with all regulated products, there are many regulations governing the development of medical devices. The medical device industry specific regulations are primarily driven by the US (FDA), Europe (European Commission), and Canada (Health Canada). Within the US, the FDA governs medical devices primarily through 21 CFR 820.30 (Quality Systems Regulation, Subpart C Design Controls) , which contains requirements similar to ISO 13485. The sections of the Quality Systems Regulation for Design Controls can be mapped fairly directly to ISO/IEC/IEEE 15288 (2015) and the INCOSE *SE Handbook* (INCOSE 2015).

Table 1. Comparison of Healthcare Safety Regulations with ISO/IEC/IEEE 15288 and the INCOSE *SE Handbook*.

21CFR820.30	**ISO/IEC/IEEE 15288:2015**	**INCOSE *SE Handbook v4 (2015)***
(b) Design and development planning	6.3.1 Project Planning Process	5.1 Project Planning Process
(c) Design input.	6.4.2 Stakeholder needs and requirements definition process 6.4.3 Systems requirements definition process	4.2 Stakeholder needs and requirements definition process 4.3 Systems requirements definition process
(d) Design output	6.4.5 Design definition process 6.4.7 Implementation process	4.5 Design definition process 4.7 Implementation process
(e) Design review	6.3.2 Project Assessment and Control process	5.2 Project Assessment and Control process
(f) Design verification	6.4.9 Verification Process	4.9 Verification Process
(g) Design validation	6.4.11 Validation Process	4.11 Validation Process
(h) Design transfer	6.4.10 Transition Process	4.10 Transition Process
(i) Design changes	6.3.5 Configuration Management Process 6.4.13 Maintenance Process	5.5 Configuration Management Process 4.13 Maintenance Process
(j) Design history file	6.2.6 Knowledge Management Process	5.6 Information Management Process

In the biomedical and healthcare environment, an important differentiator in Risk Management activities compared to other industries (see Risk Management) is that the users and patients are the center of risk analysis rather than technical or business risks. Risk management is an important element of the design control process, as preliminary hazard analysis drive initial design inputs. Traceability between identified risks, risk mitigations, design inputs, and design outputs is a key factor in product clearance through regulatory agencies. Most regulatory bodies have recognized ISO 14971: Medical devices -- Application of risk management to medical devices as a methodology for assessing and documenting product safety and effectiveness.

Usability Engineering is an important subset of risk management activities. ISO 62366-1 Medical devices – Part 1: Application of usability engineering to medical devices provides a "process for a manufacturer to analyze, specify, develop and evaluate the usability of a medical device as it relates to safety. This usability engineering (human factors engineering) process permits the manufacturer to assess and mitigate risks associated with correct use and use

errors, i.e., normal use.“ . (IEC 62366-2015) For example, for a device designed for home care use, there are many complex interfaces that product designers must consider. Patients may be physically or cognitively affected (age, medication, injury, etc.); they may be untrained or cared for people who are untrained; they are not professionals used to technical systems, etc. Even in the hospital setting, untrained patients may have physical access to systems. This puts a critical focus on usability and human factors considerations and the complexity of the use environment.

Further, as medical devices incorporate more software and become cyber-physical devices, the regulators are also focusing on privacy and security (ISO 21827) and software life cycle management (ISO 62304).

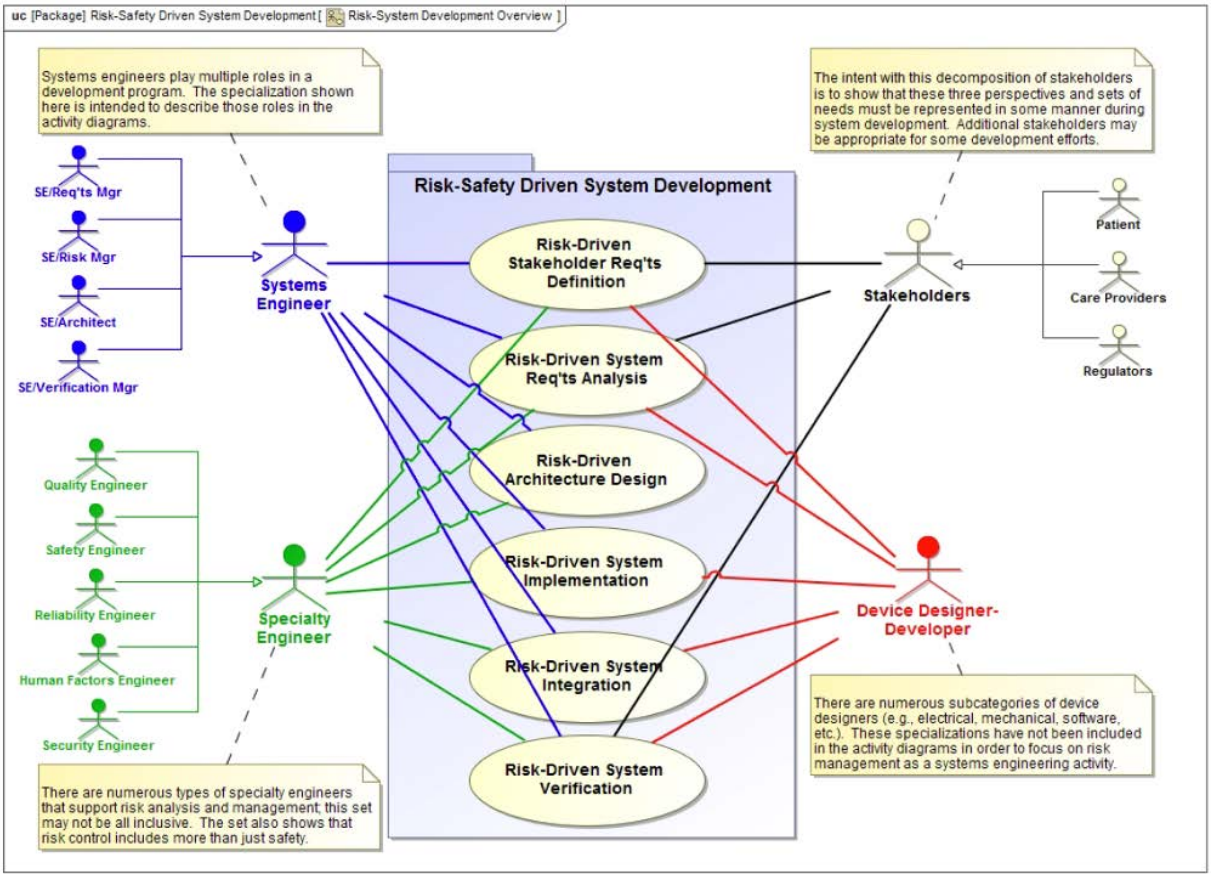

Figure 1 Overlap of Regulations and Standards for Medical Device Development. (Modified from (Malins et al. 2015). Used with Permission. All other rights are reserved by the copyright owner.)

Medical Device regulations, guidance, and technical standards are constantly changing, adding a complex dynamic to manage and incorporate throughout the product development life cycle.

Systems Engineering for Healthcare IT

Systems Engineering for Healthcare Information Technology is very similar to other IT developments, with the addition of medical regulations. Healthcare Information Technology is critical to efficient flow of information and delivery of services . (Presidents Council of Advisors on Science and Technology 2010) The product development is a mix of contract driven development (with a target customer, such as healthcare.gov), and market driven (where there are more standard products, with minimal customization). Much of the market, especially for hospitals and hospital chains, is a mix of standard products with large amounts of customization to the customer's specific needs, terminology, and workflows.

Systems Engineering for Pharmaceuticals

The pharmaceutical industry leverages systems that include hardware, software and sometimes single-use components in different part of their value chain, for example complex analytical systems during drug discovery, complex bioreactors and downstream filtration and chromatography systems in manufacturing and drug delivery devices for the use of their drugs. These systems are subject to very different regulations, e.g. GMP or medical devices, depending on the use. One challenging aspect of these systems is that the users have different skill sets and working under different environments. And in all of the examples below, biological and/or chemical processes run on these systems, requiring deep domain knowledge of the system development teams.

The in-vitro diagnostic industry also uses many systems, small devices (e.g. self-testing blood glucose or coagulation monitoring systems) all the way to large, fully automated, high throughput systems for the use in centralized laboratories. Very often, these systems operate as a closed system, so that the reagents used for the diagnostics tests, are proprietary and the vendor of the system only guarantees high quality results only when using the proprietary chemistry. This enables the vendors to often 'place' the instruments as highly competitive prices when the actual profit is generated through the consumables.

For the chemistry part of pharma, understanding the scientific method, using a systems thinking approach, and using six sigma approaches to managing variation and interdependencies is critical. Once you create a product which includes software and physical parts (including manufacturing equipment), systems engineering of the functional design, design analysis, and integration and verification of the solution become critical.

Systems Challenges for Public Health

Summits and inquiries into problems or shortcomings in the public health space have consistently uncovered the same issues: systemic failures in the way that public health is approached that make it nearly impossible to adequately respond to major health events. Examples can be seen from the US response to Hurricane Katrina (e.g. The White House 2006), the 2011 Thoku tsunami (e.g. Carafano 2011, The Heritage Foundation 2012), or even the 2014-2015 Ebola outbreak in West Africa (e.g. GHTC 2015).

The White House report provides insights into just a few of potential challenges for the health aspects of disasters or large-scale emergencies (2006, Chapter 6):

- Tens of thousands of people may require medical care.
- Large portions of a population with chronic medical conditions may themselves without access to their usual medications and sources of medical care.
- Hospitals and other healthcare facilities may be totally destroyed or otherwise rendered inoperable and the area's health care infrastructure may sustain extraordinary damage.

The types of public health challenges will also change over time: Immediate challenges include the identification, triage and treatment of acutely sick and injured patients; the management of chronic medical conditions in large numbers of evacuees with special health care needs; the assessment, communication and mitigation of public health risk; and the provision of assistance to State and local health officials to quickly reestablish health care delivery systems and public health infrastructures. (The White House 2006) As time passes, longer-term infectious disease outbreaks may occur or environmental impacts may cause health risks (e.g. Fukushima nuclear meltdown after the 2010 tsunami). And over time, the public health and overall healthcare infrastructure must be re-established and repaired.

But the public health "system" in most countries, as currently structured, is not prepared to deal with these types of challenges. In talking about the US, Salinsky and Gursky state, "Despite recent attention to the biodefense role of public health, policymakers have not developed a clear, realistic vision for the structure and functionality of the governmental public health system. Lack of leadership and organizational disconnects across levels of government have prevented strategic alignment of resources and undermined momentum for meaningful change. A transformed

public health system is needed to address the demands of emergency preparedness and health protection. … The future public health system cannot afford to be dictated by outmoded tools, unworkable structures, and outdated staffing models." (2006)

The framing of the challenge as a systems one requires the application of a systems approach, and the use of tools capable of supporting systems views, to enable better understanding of the challenges for public health and for creating ways to address these challenges. The SEBoK knowledge areas on Enterprise Systems Engineering and Systems of Systems (SoS) at least partially consider some of these challenges from a systems engineering perspective.

Systems Biology for Healthcare

As systems science is a foundation for system engineering, systems biology is becoming recognized as a foundational discipline for healthcare systems engineering. Systems biology is an emerging discipline and is recognized as strategically important when tackling complex healthcare problems. The development of systems biology is also an emerging environment for systems engineers.

According to Harvard University, "Systems biology is the study of systems of biological components, which may be molecules, cells, organisms or entire species. Living systems are dynamic and complex and their behavior may be hard to predict from the properties of individual parts. To study them, we use quantitative measurements of the behavior of groups of interacting components, systematic measurement technologies such as genomics, bioinformatics and proteomics, and mathematical and computational models to describe and predict dynamical behavior. Systems problems are emerging as central to all areas of biology and medicine." (Harvard University 2010)

As systems biology matures, its integration into healthcare approaches is expected to lead to advanced practices such as personalized and connected healthcare and the resolution of complex diseases.

Conclusion

While systems engineering practices apply to the healthcare domain, they face different challenges than other industries and need to be tailored. In fact, different segments of the healthcare industry can take significantly different approaches to effective systems engineering and systems thinking.

Overview of the Healthcare Sector

- Lead Author:
- Chris Unger
- Contributing Author:
- Cyrus Hillsman

-

This article describes some of the stakeholders of the healthcare sector and the factors which influence the application of systems engineering within it. For an overview of healthcare systems engineering and how it deals with these influences see the Healthcare Systems Engineering article.

The healthcare sector is a complex system made up of people, facilities, laws and regulations. It addresses current health, tries to ensure wellness, treats medical problems; creates new medication and medical devices; manages the health both individuals and populations; and helps determine regulations for safety, privacy, the environment, and healthcare delivery itself.

Stakeholders

There are many types of stakeholders in the healthcare sector. The space covers everyone from the general public – who have a stake in their own health and the health of those around them for issues like infectious disease – to the individual researchers who investigate current healthcare problems. The high-level groups of stakeholders include:

- The general public;
- Healthcare providers (such as doctors, nurses, clinics, and hospitals);
- Payers (such as insurance companies);
- Public health organizations;
- Researchers, scientists, and corporations in the pharmaceutical industry;
- Medical device manufacturers;
- Policy makers (particularly those with interest in public health, healthcare safety or privacy policies);
- Healthcare information technology technicians and organizations; and
- Professional organizations and societies relevant to the various aspects of the space.

The healthcare sector is an enormous area financially as well. For example, out of $2.87 trillion on healthcare spent in the US in 2010, the breakdown of components is:

US Healthcare Expenditures in 2010 (information from Emmanual 2014)

Hospital Care	$921B
Physician Services	$555B
Prescription Drugs	$280B
Nursing Home Care	$151B
Other Medical Products	$113B
Dental Services	$93B
Government Public Health	$84B
Other Professional Services	$79B
Home Health Care	$77B
Research	$48B

The sections below provide insight into the landscape for these the stakeholder groups where there is sufficient information currently available. More detail will be added as the healthcare aspects of the SEBoK mature and the team will take particular care to incorporate additional information from outside the US going forward.

Healthcare Delivery

The largest share of the money spent on healthcare in the US healthcare is in hospitals (almost a third). The number of hospitals has been relatively flat for the last 20 years. However, due to the growing cost pressures and increasing paperwork, there has been a general consolidation of hospitals into chains, and independent physician providers into hospitals or group practices. (Emmanuel 2014)

Overall Hospital Landscape (information from (AHA 2014))

Total Number of All U.S. Registered * Hospitals	5,627
Total Number of U.S. Community ** Hospitals	4,926
Total Number of Nongovernment Not-for-Profit Community Hospitals	2,870
Total Number of Investor-Owned (For-Profit) Community Hospitals	1,053
Total Number of State and Local Government Community Hospitals	1,003
Total Number of Federal Government Hospitals	213
Total Number of Nonfederal Psychiatric Hospitals	403

Hospitals range from small community hospitals to the New York-Presbyterian Hospital/Weill Cornell Medical Center with 2,259 beds (Becker 201)], or the University of Pittsburgh Medical Center Presbyterian with $12B in revenue in 2013. (Becker 2013).

Hospital chains tend to be less than 10 hospitals, with less than 10 chains having more than 10 hospitals (Becker 2015). The largest two have almost 200 hospitals (Community Health Systems with 188 and Hospital Corporation of America with 166). The largest systems by revenue are Kaiser Permanente and the Veterans Health Administration with revenue or budget of slightly over $50B each.

Medical Devices Manufacturers

The medical device development landscape is diverse, composed of many markets of intermediate size (many being above $10B in size, with high single digit to double digit growth rates). Some examples are, with projected market sizes in 2020, are:

Types of Medical Devices and Projected Market Share (Emmanuel 2014)

Medical Device Type	*Projected Market Share*
In-vitro diagnostics (IVD)	$75B
Endoscopy	$33B
Interventional Cardiology	$27B
Infection control	$17B
Minimally invasive surgery	$14B
Defibrillators	$13B
Dental Implants	$10B
Infusion pump	$ 7B
Magnetic Resonance	$ 7B
Digital Xray	$ 5B

As described in Healthcare Systems Engineering, this is the area of the healthcare sector that is most closely aligned with classic product-focused businesses.

Healthcare IT

There is a large uncertainty in what constitutes Healthcare IT. The most visible segment is the Electronic Medical Record (EMR) or Electronic Health Record (EHR), but there is also large markets in billing management, clinical decision support, image management, etc. But there is a divergence of market sizes with estimates around $60B [Bain, FierceIT] and some around $104B [Markets and Markets, MedGadget, and PRNewswire].

An EHR installation at a hospital is similar to an Oracle database installation at a company, where much of the cost is customizing the database and workflows to the institution's policies and workflows, and in training the users to the new system and standardized practices which come with IT and automation.

The top 10 Healthcare IT solution providers in 2015 (information from (Healthcare Informatic 2015))

Company	*2015 Revenue*
Optum	$5.2B
Cerner Corp.	$3.4B
McKesson	$3.1B
Dell	$2.9B
Cognizant	$2.7B
Philips	$2.7B
Xerox	$2.4B
Siemens	$2.0B

Epic Systems Corp.	$1.8B
GE Healthcare	$1.5B

Public Health Systems

The World Health Organization (WHO) defines public health as “all organized measures … to prevent disease, promote health, and prolong life among the population as a whole. Its activities aim to provide conditions in which people can be healthy and focus on entire populations, not on individual patients or diseases. Thus, public health is concerned with the total system and not only the eradication of a particular disease.” (WHO 2016) Governments at each level define exactly what “public health” will encompass, but typically there are three areas: epidemiology, provision of health services, and workplace and environmental safety and policy. Epidemiology is the study and control health-related events, including disease. Various methods can be used to carry out epidemiological investigations: surveillance and descriptive studies can be used to study distribution; analytical studies are used to study determinants.” (WHO 2016, “Health topics: Epidemiology”). Health services may include services such as preventive vaccinations, disease screening, or well-baby or well-child programs. Environmental safety can include developing policies for automobile or workplace safety, monitoring the quality of drinking water, or even conducting restaurant health inspections. In addition to these wide varieties of work, public health organizations are increasingly expected to be responsible for the health-related aspects of disaster and emergency response efforts.

In the US, the public health “system” is really a patchwork of independent healthcare departments. Each state or territory defines the scope and responsibilities of its own public health “department”, requiring information and cooperation from hospitals, private physicians, emergency personnel, laboratory networks, and sometimes public health organizations from other states. (Gursky 2005)

Conclusion

In addition to each group of stakeholders being complex in itself, these stakeholders then interact and work together - or sometimes contradict one another. This makes the landscape of the healthcare systems engineering space itself complex and highlights the need for systems thinking and systems approaches when attempting to address any health-related issues or challenges.

Systems Engineering in Healthcare Delivery

- Lead Author:
- Cyrus Hillsman
- Contributing Authors:
- Chris Unger and Nicole Hutchison

-

The healthcare system is complex and adaptive and confronts significant challenges for which systems engineering tools are useful and necessary. The President's Council of Advisors on Science and Technology (PCAST) prepared a report concluding that healthcare improvement could be accelerated with the use of systems engineering. (PCAST 2014) They noted that they key incentives are wrong (fee for service vs. fee for outcomes), and key enablers are missing (access to useful data, lack accepted systems techniques and people trained in systems engineering)

This article provides an overview of healthcare delivery with some historical context, and describes some different approaches to systems engineering which have been found helpful in addressing healthcare delivery problems.

Human Centered Design

Healthcare delivery is not a product but a service and that makes it different than typical hardware or software design that may be seen in aerospace, defense, or even medical devices. There are three primary factors for these differences. First, quality in services can be difficult to measure objectively. Second, in this service system, care providers are continually making risk, cost, and quality of care decisions at the time of service. Each patient is unique and multiple pathologies and value streams are possible based upon any given patient's needs. Those needs are complemented by a care team that is unique and complex and includes the patients themselves, family support, medical professionals, hospitals, and even the industry in which it resides. Third, if returning to or maintaining wellness is considered to be the core value for a healthcare delivery system, then the patient's behaviors both within and outside any designed care plan has a significant role to play, because roughly half of all healthcare cost is derived from preventable disease. (Conover 2012)

Structure of the Healthcare Delivery Industry

The healthcare industry is large, diverse, and fragmented and this causes considerable complexity. This complexity is experienced both at the macro and micro levels.

At the macro level the healthcare industry is highly fragmented with over 50% of all healthcare workers employed in companies with less than 500 employees. (Griffith & White 2007) Nearly 1 million physicians practice medicine in the US; roughly half of these are in primary care and the rest are in over 30 specialties and many more subspecialties and clinics. In addition to physicians, some 5 million others in some 50 other specialties provide care to patients.

At the micro level, the complexity and pace of change make care difficult. Healthcare is a rapidly developing field with over 700,000 publications produced annually and the pace in fact is increasing. (Smith et al. 2013). That there are already 14,400 codes in the World Health Organization's *International Statistical Classification of Diseases and Related Health Problems* (ICD) complicates the issue. Add to this the regulatory and administrative burden of primary care providers interacting with approximately 200 specialists in any given year and the complexity that care providers face on a daily basis becomes clear.

In short, the healthcare delivery system is itself a complex adaptive system and represents a wicked_problem_, whereby any changes to the system intended to solve an issue will likely create other issues.

Improving Ongoing Operations

As mentioned, above caregivers are faced with many challenges and the goal of in systems engineering in healthcare delivery is to lessen that burden in a systematic way without significant disruption of current operations. To do this successfully requires several factors:

- First, as stated above, systems engineers have to acknowledge that they are dealing with a complex adaptive system that includes many wicked problems. An analogy is that what systems engineers experience in healthcare is like rewiring a house with the power turned on because whatever changes are made are to an existing system that must operate while the changes are being made.
- Second, “the system” in place is difficult to define. The "healthcare system" is actually a combination of many open systems and interdependencies with the system of interest may be unknown.
- Third, patient safety is always a concern and any actions that could affect patient safety must be very carefully considered. Often, "optimizing" a system may introduce a potential risk to patient safety. These system aspects are always in tension.
- Fourth, there is a bias towards the current (known) system versus a change leading to an unknown system. Any change will create a certain amount of disruption to an operational system that may be currently operating at or beyond capacity.
- Fifth, healthcare delivery systems are combinations of patients, providers, process, and products and therefore uncertainty is a daily reality. This level of uncertainty may not be amenable to typical agile approaches of 4-6 week sprints nor traditional waterfall methods.
- Sixth, local factors could play a significant role; therefore no two sites may perform an operation in exactly the same way.
- Seventh, the entire industry acts as a complex adaptive system with multiple intelligent agents working sometimes in partnership and sometimes in conflict with the goals of the system or patient.

Because of these factors and others the tradition of healthcare systems engineering has been to use adaptable human-centered methods. (Checkland 1999)

History of Healthcare Improvement Research

There have been many attempts to understand and improve healthcare both in the public and private domains. Examples include the National Healthcare Service Change Model, the efforts of the Agency for Healthcare Research and Quality, and the Institute for Healthcare Improvement. Here we outline some representative efforts.

Healthcare improvement has been shaped in part by four seminal works by the Institute of Medicine (IOM). *To Err is Human* reported that up to 98,000 patients were killed by healthcare each year. (Kohn, Corrigan, & Donaldson 2000) This put an emphasis on safety as a key quality of care metric. The following year the Institute of Medicine (IOM) broadened the concept of quality beyond safety to include six measures of quality. They determined that healthcare should be safe, effective, patient centered, timely, efficient, and equitable. (Institute of Medicine 2001) This report called Crossing the Quality Chasm included an appendix that documented poor quality and the severity of the issues of under use, over use, and potential for harm in medicine. A search for the underlying reasons for poor quality led to three primary reasons for poor quality. The three reasons were the growing complexity of science and technology; the increase in chronic conditions; and the failure to exploit information technology.

To address these concerns the IOM partnered with the National Academy of Engineering (NAE) to see what could be done from a systems engineering perspective to address the real challenges facing the industry in Building a Better Delivery System. (Compton et al. 2005). That was followed by the realization that standard systems engineering needed to be modified and healthcare was and would remain a human centered endeavor as stated in Best Care at Lower Cost (Smith et al. 2013)

Three Approaches

Although there are many accepted approaches to healthcare systems engineering and improvement, here we outline three that share common characteristics and are representative of most of the other methods.

The first approach is Lean Six Sigma which is a combination of two methods. Lean has its roots in the Toyota Production System (Ohno 1988) and the work of the International Motor Vehicle Program (Womack, Jones, & Roos 1990). Six-Sigma has its roots at Motorola and the work of Bill Smith. These two methods were combined by Michael L. George (see (George 2002) and (George 2003)). It includes techniques like value stream mapping, waste elimination, root cause analysis, and voice of customer. For additional information see Lean Engineering and Lean in Healthcare.

The second approach is based on industrial engineering, which has its roots in the work of Frederick Taylor and others. This approach includes tools such as discrete event simulation, ergonomics, production control, and operations research as shown in Figure 1. For additional information, see Systems Engineering and Industrial Engineering.

Insert Table ES-1 from Building a Better Delivery System here once we obtain the proper permissions.

The third approach is healthcare systems engineering. Traditional systems engineering uses a functional decomposition approach; see for example (Defense Systems Management College 2001). However, healthcare problems are often classified as wicked and complex and not amenable to traditional decomposition methods found in other areas of engineering. (Rouse & Serban 2014).

There are many tailored approaches to improving healthcare delivery, but almost all are based on one of these three approaches, or a combination of these.

Healthcare Systems Engineering

The basic systems engineering steps are similar to those for any industry specific applications, but the steps are tailored for healthcare. The traditional waterfall model of requirements, design, implementation, verification, and maintenance is interrupted in favor of almost continuous support. In many cases the closeout and transfer of the project to operational staff is more challenging in healthcare than in many industries.

Below is outlined a general methodology used by the US Department of Veteran's Affairs (VA) that may suit a wide variety of situations and programs, composed of 4 pillars: Define the Problem, Investigate Alternatives, Develop the Solution, and Launch and Assess the Solution. These 4 pillars are similar to classic mistake avoidance, development fundamentals, risk management, and schedule oriented approaches. (McConnell 1996); they are also similar to the Plan/Do/Check/Act methodology.

Define the Problem

As mentioned above, the patient is augmented by a care team consisting of family, friends, clinical staff, and many other support staff the patient will not directly encounter. This care team may not be familiar with the rigors of traditional engineering design. Because of this, a systems engineer may use a paired partnership model where engineers are embedded with clinical and administrative staff, family, and the patients themselves. In this concept, everyone is a designer and our goal is to provide them with the tools to contribute to the system design process. Even at this early stage, configuration management would be considered. Depending on the size of the rollout one alpha site and several beta sites may be used at any phase to avoid local optimal solutions that don't work globally.

Investigate Alternatives

During the proof-of-concept phase, visualizing the result is important for the reasons mentioned above. Therefore, one or more initial prototypes may be developed with the alpha site. The goal is to get to a minimally viable product as soon as possible to demonstrate the viability of the product or methodology. After the initial conversations and meetings, participants have a need to have a common understanding of how the system will work. The systems engineer would embrace the concept of operations with rich pictures, model based systems engineering, story boards, customer journey maps and other tools so that we all have a common understanding of the proposed system.

Develop the Solution

Using what has been learned from the minimally viable product feedback and incorporate that into the future state optimization, one would continue developing the prototype at the initial paired partner alpha site and then the trusted beta demonstration sites. In our case, stakeholders are a part of the development team and not an ancillary function. For this reason, demonstration is considered a key element of the communication plan when developing the solution.

Launch the Solution and Access the Performance

During evaluation and deployment phase, a systems engineer would have considered the future state optimization with corresponding alpha and beta sites. Live implementation would then be used for further testing and evaluation. At any phase feedback is encouraged and reflected in the next iteration of the solution. As mentioned previously abandonment and closeout even during the live phase may not be practical and in fact could be disadvantageous because not all possible needed configurations or situations would have been encountered.

Example Systems Engineering Tools

Below is a list of systems engineering tools which could be used at each of the four steps.

1. Define the Problem
    1. Establish the scope and context of the problem (define boundary conditions)
    2. Stakeholder identification and management
    3. Lifecycle mapping
    4. Value Stream Process Mapping
    5. SWOT analysis (Operational Deficiencies and Technological Opportunities)
    6. Workflow/Usability/Use Case analysis
    7. Observation Research
    8. Root Cause Analysis (Fishbone diagrams, 5 whys, …)
2. Investigate Alternatives
    1. Requirements management
    2. SE Evaluation Methods (Decision Trees, Quality Function Deployment (QFD))
    3. Trade-off Analysis
    4. Model-Based Systems Engineering (MBSE)
    5. Technical Risk Management
3. Develop the Solution
    1. Concept Development
    2. Architecting the solution (functional analysis, subsystem decomposition, interface definition and control, modeling)
    3. Define the implementation
    4. Process Redesign Techniques (including Lean Six Sigma)
    5. Active Integration

6. Agile / Lean Development Principles (iterative development)

4. Launch and Assess the Solution
    1. Managing Change in Organizations
    2. Stakeholder Management, Change Management Techniques
    3. Spiral, Agile, and Lean Startup Delivery Practices (Minimal Viable Product delivery)
    4. Business Risk Management
    5. Metrics and benchmarking

During all phases, elements of cognitive & organizational psychology, industrial engineering, usability engineering, systems engineering, and other facets may be critical to implement a solution. Humans are *the* major part of the system and even the system of systems approach in healthcare.

Conclusion

Systems Engineering for Healthcare delivery shares many aspects with traditional SE, but differs significantly since healthcare delivery is a service (not a product) and due to the domain specific challenges. In particular, problem definition is a particularly 'wicked' problem, and measuring successful outcomes in a clear and objective fashion is challenging.

-

Systems biology is the computational and mathematical modelling of complex biological systems. Systems biology is a biology-based inter-disciplinary field of study that focuses on complex interactions within biological systems, using a holistic approach to biological research. From year 2000 onwards, the concept has been used in the biosciences in a variety of contexts. For example, the Human Genome Project is an example of applied systems thinking in biology which has led to new, collaborative ways of working on problems in the biological field of genetics. One of the outreaching aims of systems biology is to model and discover emergent properties of cells, tissues and organisms functioning as a system whose theoretical description is only possible using techniques which fall under the remit of systems biology. These typically involve metabolic networks or cell signalling networks. (Wikipedia Contributors 2016)

Systems Biology: A Vision for Engineering and Medicine

Organisms and Hosts Interact in Communities of Life

There is an increasing appreciation that microbes are an essential part of the ecologically-important traits of their host. Organisms do not live in isolation, but have evolved, and continue to evolve, in the context of complex communities and specific environmental conditions. Evolutionary biologists are increasingly able to integrate information across many organisms, from multiple levels of organization and about entire systems to gain a new integrated understanding that incorporates more and more of the complexity that characterizes interdependent species associations. Only when we begin to understand the molecular base for adaptation and interactions of communities of life, can we start to comprehend how ecosystems are functioning.

Addressing Different Levels of Organization of Organisms

Understanding the function of complex biological systems is one of the greatest challenges facing science. The rewards of success will range from better medicines to new engineering materials. The sequencing of the human genome, although of fundamental importance, does not even provide a complete parts list of the protein molecules that exist in a biological organism because of complexities of downstream processing and complex folding required to make a functioning receptor or enzyme from a long chain of amino acids. Furthermore, protein molecules do not function alone but exist in complex assemblies and pathways that form the building blocks of organelles, cells, tissues, organs, organ systems and organisms, including man. The functioning of brain or muscle, liver or kidney, let alone a whole person, is much greater than the sum of its parts.

Figure 1 - Levels of Structural Organization of the Human Body (source - https:/ / cnx. org/ contents/ Xh_25wmA@7/Structural-Organization-of-the#fig-ch01_02_01)"'

Internalizing the Complexity – Pushes the Boundary of Systems Thinking Capability

To tackle this problem (understanding biological systems) requires an iterative application of biomedical knowledge and experiment with mathematical, computational and engineering techniques to build and test complex mathematical models. Systems and control engineering concepts, a modular approach and vastly increased computing capacity are of critical importance. The models, once developed and validated, can be used to study a vastly greater range of situations and interventions than would be possible by applying classical reductionist experimental methods that usually involve changes in a small number of variables. This new approach is now termed "Systems Biology". It allows insight into the large amount of data from molecular biology and genomic research, integrated with an understanding of physiology, to model the complex function of cells, organs and whole organisms, bringing with it the potential to improve our knowledge of health and disease. Systems Biology will inevitably become an approach that pervades scientific research, in much the same way that molecular biology has come to underpin the biological sciences. It will transform the vast quantities of biological information currently available into applications for engineering and medicine.

Natural Patterns and Engineered Patterns Can Be a Source of Inspiration - in Both Directions

Biological organisms are much more complicated than any machine designed by man. However, there are similarities between the way in which organs and whole organisms are assembled from molecules and cells and the design methods used by engineers in the construction of complex systems. The application of such methods to biology will, however, require novel engineering tools to be developed since biological systems possess key features that artificial ones do not. Specifically, biological systems have an exceptional capacity for self-organization and assembly, using rules and mechanisms that have been shaped by natural selection. Biological systems also have significant capacity for continuing self-maintenance through turnover and renewal of component parts. Perhaps the property that distinguishes biological systems most is their ability to auto-adapt their organization to changing circumstances through altered gene expression, or more directly, through signal transduction and modification of proteins. This adaptation culminates at higher levels of organization as evidenced by phenomena such as the development of resistance to antibiotic therapy or tolerance to recreational drugs. The mechanisms by which component parts interact are often highly stochastic in nature; that is, susceptible to the play of chance, which becomes particularly important when only a few components are being considered. Nevertheless, biological systems are robust.

Advancements in Methods for Predicting “What If” in the Behavior of Complex Adaptive Systems

Advances in engineering design and techniques carry a significant potential in driving the progress of Systems Biology. Interventions to biological systems intended to improve health, whether environmental, pharmacological or clinical, need to be carefully thought through and carried out to maximize benefit and reduce harm. The refinement of techniques and tools enables devices and systems to achieve a defined performance within precise tolerance limits, potentially allowing better interventions to complex biological systems. They will be increasingly necessary to permit more reliable system-wide predictions of the effects of biomedical advances and to achieve desired clinical results to a predefined tolerance, or at least to have a quantitative bound on the biological uncertainty.

Transdisciplinary Approaches are Needed to Address the Complex Bio-system Problems

Research in the field of Systems Biology requires close interactions and collaborations between many disciplines that have traditionally operated separately such as medicine, biology, engineering, computer science, chemistry, physics and mathematics. Systems Biology demands a focus on the problem as a whole and therefore a combination of skills, knowledge and expertise that embraces multiple disciplines. The success of leaders in the field of Systems Biology will depend strongly on the extent to which they accomplish the creation of the environment that researchers need to develop an understanding of different working cultures, and manage also to implement strategies that integrate these cultures into shared working practices.

Systems Biology: Relevance to Healthcare

Complex Diseases Demand Systemic Approaches

Over the past few decades, pharmaceutical R&D has focused on creating potent drugs directed at single targets. This approach was very successful in the past when biomedical knowledge as well as cures and treatments could focus on relatively simple causality. Nowadays, the medical conditions that affect a significant proportion of the population in industrialized countries are more complex, not least because of their multifactorial nature. The sequencing of the human genome has led to a considerable increase in the number of potential targets that can be considered in drug discovery and promises to shed light on the etiology of such conditions. Yet, the knowledge of the physiological properties and the role that these targets play in disease development is still limited.

Diminishing Returns in the Single Target Approach to Disease

In terms of drug targets, there is a case that much of 'the low hanging fruit' was picked in the period between the late 1940s and the mid-1980s. The decline in output of new molecular entities and medicines recorded over the last 20 years, despite the steadily growing R&D expenditure and significant increase in sales, bears testimony to the fact that advances with new targets are more difficult and that R&D projects have become much more prone to failure. A basic problem is that the many factors that predispose to, and cause, complex diseases are poorly understood let alone the way in which they interact. The very fact that there are multiple drivers for these conditions suggests that a reductionist approach focusing on individual entities in isolation is no longer appropriate and may even be misleading. It is therefore necessary to consider 'novel' drugs designed to act upon multiple targets in the context of the functional networks that underlie the development of complex diseases. Many of the new developments are likely to turn into effective medicines when combinations of drugs are used to exert a moderate effect at each of several points in a biological control system. Indeed, many common diseases such as hypertension and diabetes are already treated with a combination of two or three medicines hitting different targets in the control network that underlies the condition. Investigating the possible combinations by trial and error in man is onerous but feasible with two components. However, it quickly becomes extremely complicated with three components and well-nigh impossible with four or more. Systems Biology, promises to assist in the development of more specific compounds and in the identification of optimal drug targets on the basis of their importance as key 'nodes' within an overall network, rather than on the basis of their properties as isolated components.

Individualized Medicine, Tuned to the Individual and Their Circumstances

Increasingly powerful drugs will be aimed at a decreasing percentage of people and eventually at single individuals. Modelling can be used to integrate in vivo information across species. Coupled with in vitro and in silico data, it can predict pharmacokinetic and pharmacodynamics behavior in humans and potentially link chemical structure and physicochemical properties of the compound with drug behavior in vivo. Large-scale integrated models of disease, such as diabetes and obesity, are being developed for the simulation of the clinical effects resulting from manipulations of one or more drug targets. These models will facilitate the selection of the most appropriate targets

and help in planning clinical trials. Coupling this approach with pertinent genomic information holds the promise of identifying patients likely to benefit most from or to be harmed by, a particular therapy as well as helping in the stratification of patients in clinical trials. Symptoms that diagnose a disease do not necessarily equate to a common cause.

Systems Biology is arguably the only research approach that has the potential to disentangle the multiple factors that contribute to the pathogenesis of many common diseases. For example, hypertension, diabetes, obesity and rheumatoid arthritis are known to be polygenetic in origin although individual genes may not have been identified. Ultimately, the prevention of these conditions rests upon a comprehensive approach that engages with each of the more important predisposing factors, genetic and environmental, that operate upon individuals. A systems approach is already proving valuable in the study of complex scientific subjects and the research aimed at the prevention and management of medical conditions. Illustrative examples are neuroscience, cancer, ageing and infectious diseases.

A Healthcare Paradigm Reinforcing the Causes of Health and Not Just the Treatment of Disease

Notwithstanding the hugely important role that Systems Biology plays in understanding disease and designing drugs that treat them, the greatest opportunities may lie in health maintenance and disease prevention. Even modest measures that could retard the effect of ageing on brain, heart, bones, joints and skin would have a large impact on the quality of life and future healthcare demands of older people and consequently on the provision of health services. Young people are vulnerable too. Multifactorial diseases such as diabetes, obesity, allergies and autoimmune conditions are becoming prevalent in younger people and unless effective measures are taken to prevent an early and significant decline in their health, healthcare demand will increase exponentially. It is apparent that multiple and diverse factors interact in determining health, quality of life and ageing. These include genetic makeup, microbiota, diet, physical activity, stress, smoke and alcohol, therapeutic and social drugs, housing, pollution, education, and only a systems approach will permit the understanding of how best to prevent and delay health decline.

Lean in Healthcare

- Lead Author:
- Bohdan Oppenheim
- Contributing Authors:
- Chris Unger and Nicole Hutchison

-

Lean Thinking, or Lean for short, originated in Toyota factories in the 1960s, was “transplanted” to the U.S. in 1992 with the publication of Womack and Jones' *Lean Thinking: Banish Waste and Create Wealth in Your Corporation* (2003), and evolved globally to practically all work domains: healthcare, engineering and systems engineering, science, administration, supply chain, government, banking, aviation, and many others (Oppenheim 2011). Lean has proven itself as the most effective methodology for improving operations identifying and eliminating waste from work processes. (E.g. Womack and Jones 2003; Oppenheim 2011; Graban 2012; Toussaint and Gerard 2010; and Oehmen 2012) Since 2003, Lean has established itself in healthcare operations.

Overview of Lean in Healthcare

Entire medical organizations (e.g., Theda Care, WI; Jefferson Healthcare, WA; Virginia Mason, WA; Geisinger Health (now called ProvenCare), PA; St. Elizabeth, Tilburg, The Netherlands, and numerous others (e.g. Graban 2012; Toussaint and Gerard 2010)) have been transformed with Lean. These sources contain rich data on specific improvements. Most leading healthcare institutions now have Lean centers of excellence or use Lean consultants, including Kaiser Permanente, Mayo Clinic, UCLA, Veterans Administration, and others. Lean has proven itself in reducing turnaround time of clinical tests, the time spent by patients in emergency departments, operating suites, pharmacies and clinics. Lean improvements in healthcare on the order of 30-50% are routine because traditional healthcare operations are burdened with this much waste, which remains “unseen” by the employees unless they are trained in Lean. Lean is now an established paradigm for improving healthcare delivery operations: increasing quality of healthcare, delivering care faster, shortening patient time in the system, increasing the time of medical professionals with the patient, reducing bureaucracy, increasing capacity of operations, and reducing healthcare costs and frustrations. (Graban 2012; Toussaint and Gerard 2010)

Lean does not mean that people have to work faster or "attach roller blades to move around faster". In Lean, systems employees work at their regular ergonomic and intellectual speeds. The time savings come from finding and eliminating idle states (e.g., waiting in numerous queues in the emergency departments), reduction of mistakes and rework, elimination of non-value adding tasks, and more streamlined movements of patients, staff, equipment, and supplies. And, most emphatically, Lean does not mean “mean layoffs”. Quite the opposite is true: Lean improves human relations at work and changes the culture from the traditional "blaming and shaming" to teamwork and cooperation focused on the good of the patient. (Graban 2012 (in particular see the endorsements from eight medical professionals on pages ii and iii) and (Toussaint and Gerard 2010)

With the endorsement of *Lean for Systems Engineering with Lean Enablers for Systems Engineering in the Wiley Series*, (Oppenheim 2011) the International Council on Systems Engineering (INCOSE) has effectively adopted Lean as one of its essential competencies. This book was followed with a major joint Project Management Institute (PMI)-INCOSE-MIT publication of (Oehmen 2012) integrating Lean with Systems Engineering and Program Management. Indeed, when applied with Systems Engineering and Systems Thinking, Lean becomes a powerful weapon in bending the healthcare cost curve and improving the quality of care.

Three concepts are critical to the understanding of Lean: value, waste, and the process of creating value without waste, which has been captured into the so-called Six Lean Principles, as follows.

- **Value**: M. Porter (2010) suggested that patients value three levels of care: (1) survival and the degree of recovery; (2) the time required to get back to normal activities, and (3) the sustainability (individual and social cost) of treatments.
- **Waste**: Table 1 lists the eight categories of waste used in healthcare. (Graban 2012; Toussaint 2010)

Table 1. Eight Waste Categories Used in Lean Helathcare (SEBoK Original).

Waste Type	Healthcare Examples
1. Waiting	Patients wait in numerous queues in clinics, test facilities, ERs, pharmacies, and for insurance approvals; MDs wait for next activity to occur (e.g. test results, information, approvals.)
2. Over-processing	Performing work that is not valued or needed, e.g. MDs and RNs spending time on computer filling out bureaucratic forms that nobody will review.
3. Over-production	Performing more work than needed for value. Transport of a patient in a wheelchair performed by expensive medical professionals because of the lack of transporters.
4. Inventory	Excess inventory costs. Expired supplies that must be thrown away.
5. Transportation of Patients	Transportation of patients over long distances to test offices in hospitals. Poor layout of hospitals, EDs, or test facilities.
6. Motion of Staff	Staff walking over long distances to fetch supplies, and between patients and central hospital stations.
7. Defects	Treatment of hospital infections. Failed and repeated tests, repeated paperwork. Surgical cart missing an item. Wrong medicine.
8. Waste of Human Potential	Burnout of medical staff. Frustrated employees quit making suggestions for improvements.

Table 2 lists the six Lean Principles (Graban 2012) and provides healthcare examples.

Table 2. Six Lean Principles (SEBoK Original)

Principle Name	Explanation
1. Value	Specify value from the perspective of the customer: the patient.
2. Value Stream	Identify all the value-added steps across the entire process, crossing all departmental boundaries, linking the steps into a seamless process, and eliminating all steps that do not create value.
3. Flow	Keep the processes flowing smoothly through all the steps, eliminating all causes of delay, such as batches of patients or items, and quality problems.
4. Pull	Avoid pushing work onto the next step or department; let work and supplied be pulled, as needed, when needed.
5. Perfection	Pursue perfection through continuous improvement, Kaizen events, implement best work standards, checklists, training, and promote improvement teams and employee suggestions.
6. Respect People	Create work environment based on synergy of cooperation, teamwork, great communication and coordination. Institute leadership. Abandon the culture of blaming and shaming.

Lean Practices

Lean healthcare strongly promotes engaging and leading employees. Lean places a big value on continuous education and training of employees at all levels. Lean management promotes standardization of best practices ("the best known way of doing it", but not necessarily "identical"), checklists, redundancies, patient safety and privacy rules, and patient data security and cybersecurity. Lean advocates visual management, with electronic or "black" boards updated in real time and displaying all information important for the local employees to manage their operation efficiently. Patient safety is still a significant problem in the U.S., in 1999 causing almost 250,000 deaths (Institute of Medicine, 1999) and medical errors occur in one of three admissions. Instead of "blaming and shaming" Lean promotes error and harm prevention and deep root-cause analysis, implementing processes and tools that make it impossible to create an error.

Systems Thinking and Lean

Healthcare is the most complex socio-technological system in our society, consuming nearly 20% of the U.S. GDP. Healthcare should be safe, effective and evidence based (Berwick 2011), as well as affordable and accessible, efficient, patient centered, timely, well integrated, and inclusive of latest science. (Oppenheim 2015) Healthcare has many stakeholders: the patients, medical professionals, medical facilities, hospitals, clinics, labs, medical equipment makers and users, pharmaceuticals, healthcare researchers and academia, insurances, employers, federal & state governments and international disease prevention centers, military and veteran's administration, fire departments and ambulances and others. The number of potential interactions (interfaces) in this hyper-system is extensive, and many interfaces are nonlinear, "wicked" (interacting with unpredictable humans), often creating unintended consequences and emergent behaviors. Because of these vast complexities, healthcare leaders (e.g. Kanter 2015) point out the need for intensive application of systems thinking and Lean when addressing these challenges. Attempting to solve the complex healthcare problems without systems thinking risks myopic and unsafe attempts which create more problems than they solve. Attempting to solve the challenges without Lean inevitably promotes excessive wastes, costs, and inefficiencies. Good healthcare needs both, Systems Thinking and Lean, to be applied simultaneously.

Lean and Agile in Six Healthcare Value Streams

The Healthcare Working Group of INCOSE identified six following value streams for HSE: A. Systems Engineering for medical devices B. Systems Engineering for healthcare informatics and medical records C. Healthcare delivery (operations) D. Biomedicine and big data analytics E. Pharmaceutical value streams F. Healthcare public policy

As described above, Lean is extraordinarily effective and well established in improving healthcare delivery operations (C). Agile is highly effective in (B) because this value stream works with software, the domain from which Agile originated. Since the stream (A) is the most similar to traditional systems engineering, Agile is expected to be effective therein, although Agile is not yet highly popular in healthcare outside of the software domain. Elements of Lean improvements which are localized and weakly convoluted (e.g., Kaizen events) have strong overlap with Agile/Scrum methodology. (Medinilla 2014)

MBSE and Lean

A highly powerful Model Based Systems Engineering (MBSE) is clearly the tool of choice for those applications where the benefit from multiple use of a standardized (reference) architecture and standard model compensates for the significant effort of creating such a model or architecture. (OMG 2016) In healthcare the value streams (A), (B), (E) and potentially F are the most conducive to the application of MBSE. Lean thinking is applicable to any healthcare operation without limitation. The Lean improvements always begin with the so-called Gemba waste walks, during which experts together with local process stakeholders walk along all the process steps, interviewing stakeholders and identifying and measuring the wastes wherever they occur. The rich menu of Lean thinking

processes and tools is then applied to eliminate the wastes. Training and active participation of local stakeholders is always required.

Examples of Lean Improvements

1. In Jefferson Healthcare, WA: (Murman 2010)
   - In Acute Myocardial Infarction (a severe heart attack) time is critical as the greatest loss of heart muscle is in the first two hours. Recommended treatment is catheter insertion of balloon within 90 min of the contact with the patient (wherever the patient happens to be located). The Lean approach has reduced the treatment time from 165 min to 20-60 min at the patient site, vastly increasing patient survival rate.
   - The five Jefferson Healthcare clinics increased the cumulative available clinic hours from 1400 to 5600 in two years of Lean improvements which were focused on reorganizing medical staff schedules and eliminating wasted times, with no staff additions. The available clinic hours directly translate into billable visits: 1175 additional patients have been seen in 2009 compared to 2008 across the five clinics.
   - The Operating Room daily "on time start" of actual operations went from 14% to 96% using Lean tools for process planning and workplace organization.
   - Harder to measure is the culture change, although the staff participation at Lean improvement events was at 50%.
2. In Kaiser Permanente Southern California: (Oppenheim 2015)
   - In nine regional clinical laboratories Lean improvements cut the turnaround time for laboratory results by between 30 and 70%, with significant corresponding reductions of cost, rework, errors and work morale, and without hiring new staff or adding equipment.
   - In two Emergency Departments (ED) the average patient length of stay was reduced by 40% by the elimination of various idle states. The ED capacity increased accordingly.
   - The amount and cost of inventory of supplies on hand was reduced by nearly 30% by introducing the Just-in-Time tools of Lean.
3. In Alegent Health, NE (Graban 2012) the turnaround time for clinical laboratory results was reduced by 60% in 2004 without adding new staff or equipment; and by another 33% from 2008 to 2010.
4. In Kingston General Hospital, Ontario (Oehmen) the instrument decontamination and sterilization cycle time was reduced by 54% while improving productivity by 16%.
5. In Allegheny Hospital, PA the central-line associated bloodstream infections were reduced by 76%, reducing patient death from such infections by 95% and saving $1 million.
6. In UPMC St. Margaret Hospital, PA (Graban 2012) the readmission rates for chronic obstructive pulmonary disease (COPD) patients were reduced by 48%.
7. In ThedaCare, WI [3] the waiting time for orthopedic surgery was reduced from 14 weeks to 31 hours (from first call to surgery); improved inpatient satisfaction scores of "very satisfied" rose from 68% to 90%.
8. In Avera McKennan, SD [3] the patient length of stay was reduced by 29%, and $1.25 million in new ED construction was avoided.
9. In Denver Health, CO [3] the bottom-line Lean benefit was increased by $54 million through cost reduction and revenue growth, and layoffs were avoided.
10. In Seattle Children's Hospital, WA $180 million in capital spending was avoided through Lean improvements.

These examples demonstrate that Lean is successful in cost and throughput time reductions, and improvements in quality and patient and staff satisfaction. The improvements of this level are possible, even routine – because the amount of initially-invisible waste in traditional healthcare organizations is so high. The broad range of operations described in the examples manifest that Lean is applicable across the board to healthcare operations, without limitations.

Education in Lean Healthcare

Increasingly, Lean Healthcare becomes an inherent part of Healthcare Systems Engineering (HSE) Master's Programs, e.g. (Loyola Marymount University 2016) which has been developed in collaboration with Kaiser Permanente. The program includes two courses in Lean, basic and advanced, focused on improving operations in clinics, hospitals, emergency departments, clinical laboratories, radiology testing, operating rooms, pharmacies, supply chain, and healthcare administration. After the basic courses in systems engineering, project management, and systems thinking, the students also take courses on healthcare system architecting, modeling and simulations; medical data mining and analytics; systems engineering for medical devices, healthcare enterprise informatics; and healthcare delivery systems. All these advanced courses contain elements of Lean thinking because all these subdomains risk being burdened with waste and poor quality if Lean is ignored. Simply put, Lean is not really an optional extra if you want to achieve efficiency and effectiveness.

-

Part 5 of the Guide to the SE Body of Knowledge (SEBoK) is a guide to knowledge about how an enterprise prepares and positions itself to effectively perform the systems engineering (SE) activities described elsewhere in the SEBoK.

SE activities — how to develop requirements, select an appropriate life cycle model, and architect a system of systems, and so on — are covered elsewhere, especially in Part 3, Systems Engineering and Management. An organization that desires to do these things effectively must work through questions like whether to allow a project manager to select the systems engineers he or she employs, and, if so, what competencies the project manager might seek in those systems engineers. These are the kinds of questions that Part 5 explores.

The discussion defines three levels of organization: enterprise or organization, team, and individual. To adapt an example to a more complex organizational structure, simply decompose enterprises into sub-enterprises and teams into sub-teams, as needed. For more about the different types of enterprises, see Engineered Systems in Part 2.

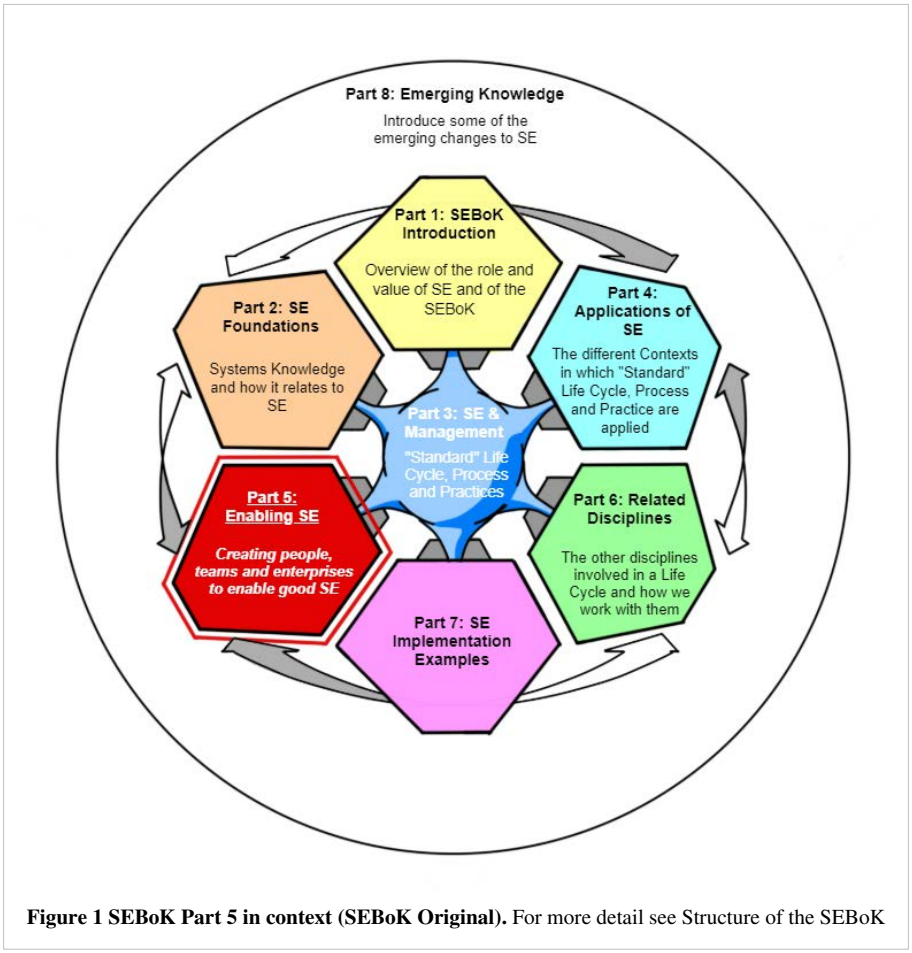

Figure 1 SEBoK Part 5 in context (SEBoK Original). For more detail see Structure of the SEBoK

Knowledge Areas in Part 5

Each part of the SEBoK is composed of knowledge areas (KA). Each KA groups topics around a theme related to the overall subject of the part.

The KAs in Part 5 explore how to the performance of systems engineering from three different lenses:

- Enabling Businesses and Enterprises
- Enabling Teams
- Enabling Individuals

Common Practices

There are as many different ways to enable SE performance as there are organizations, and every organization's approach is detailed and unique. Nevertheless, common practices, methods, and considerations do exist. Part 5 uses them as a framework to structure the relevant knowledge.

SE activities that support business needs and deliver value are enabled by many factors, including:

- Culture (see Culture),
- SE competencies (see Determining Needed Systems Engineering Capabilities in Businesses and Enterprises) and how the organization grows and deploys its workforce to acquire them, and
- SE tooling and infrastructure (see Systems Engineering and Management in Part 3).

Enterprises and Businesses

The fact that Part 5 uses two terms, “Enterprise” and “Business,” to name a single level of organization, indicates that the two are closely related. In many contexts it is not necessary to make any distinction between them: an enterprise may be a traditional business, and a business can be seen as a special type of enterprise. For the sake of brevity, the more general term "organization" may be used to mean “business or enterprise” throughout Part 5.

Traditional businesses usually have a legal structure and a relatively centralized control structure. Such a business may be a corporation, or a unit of a company or government agency, that creates a product line or offers services.

On the other hand, an enterprise can be structured in a way that excludes description as a business. This happens when an enterprise crosses traditional business boundaries, lacks a centralized legal authority, and has relatively loose governance. One example is the healthcare "system" in the US which encompasses hospitals, insurance companies, medical equipment manufacturers, pharmaceutical companies, and government regulators. Another is the set of companies that form the supply chain for a manufacturer, such as the thousands of companies whose parts and services Apple uses to create, distribute, and support the iPhone.

Significant actions that enable SE are often conducted by traditional businesses rather than by less tightly structured enterprises. Even so, organizational context affects how the business approaches SE and therefore how it enables SE performance. A business that sells to the general commercial marketplace typically has far fewer constraints on its SE practices than one which performs contract work for a government agency. A business that creates systems with very demanding characteristics, such as aircraft, typically has a much more rigorous and planned approach to SE than one which creates less demanding systems, such as a smartphone app.

Traditional businesses are intended to be permanent, and typically offer a portfolio of products and services, introduce new ones, retire old ones, and otherwise seek to grow the value of the business. Sometimes a single product or service has such value and longevity that it spawns a business or enterprise just for its creation, maintenance, and support. The Eurofighter Typhoon aircraft, for example, was developed by a consortium of three corporations that formed a holding company specifically to provide support and upgrade services throughout the in-service life of the aircraft.

For more on the distinction between businesses and enterprises and the value of systems engineering of enterprises to them, see Enterprise Systems Engineering in Part 4. Systems of Systems (SoS), also in Part 4, contrasts the tighter control over SE that is usual for businesses with the looser control that is usual for enterprises lacking a traditional business structure. Groupings of Systems in Part 2 discusses the Directed SoS to which the traditional business may be equivalent.

Teams

Teams operate within the context of the businesses in which they reside. This context determines how the team is enabled to perform SE.

For example, a business may grant a team wide autonomy on key technical decisions, which are made either by team systems engineers or in consultation with team systems engineers. On the other hand, the same business could instead create a generic set of SE processes that all teams are to tailor and use, constraining the team to adhere to established business policies, practices, and culture. The business could even require that the team gain approval for its tailored SE process from a higher-level technical authority.

Teams are usually formed for a limited duration to accomplish a specific purpose, such as creating a new system or upgrading an existing service or product. Once the purpose has been fulfilled, the team responsible for that effort is usually disbanded and the individuals associated with the effort are assigned to new tasks. Exceptions do happen, however. For example, a team of systems engineers tasked with assisting troubled programs throughout a corporation could persist indefinitely.

Part 5 on Enabling Systems Engineering explores how systems engineering (SE) is enabled at three levels of an organization: the business or enterprise (hereafter usually just called "business" --- See Enabling Systems Engineering for more information), the team, and individuals.

The **Enabling Businesses and Enterprises** Knowledge Area describes the knowledge needed to enable SE at the top level of the organization. Part 3, Systems Engineering and Management, describes how to perform SE once it has been enabled using the techniques described in Part 5. Moreover, a business is itself a system and can benefit from being viewed that way. (See Enterprise Systems Engineering in Part 4.)

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The Kas, in turn, are divided into topics. This KA contains the following topics:

- Systems Engineering Organizational Strategy
- Determining Needed Systems Engineering Capabilities in Businesses and Enterprises
- Organizing Business and Enterprises to Perform Systems Engineering
- Assessing Systems Engineering Performance of Business and Enterprises
- Developing Systems Engineering Capabilities within Businesses and Enterprises
- Barriers to Successful Embedding of Systems Engineering into Organizations
- Culture

Relationship Among Topics

- Systems Engineering Organizational Strategy describes how SE delivers value to the business, who makes decisions about SE in the business, how those decisions are made, how resources are allocated, and how the soundness and performance of those decisions are monitored.
- Determining Needed Systems Engineering Capabilities in Businesses and Enterprises describes how a business decides what specific SE capabilities are needed; e.g., a business that creates cutting edge products would likely require very strong architecting capabilities, including modeling tools. A business that has a global development team would likely need a very robust collaboration toolset.
- Organizing Business and Enterprises to Perform Systems Engineering describes various organizational models; e.g., which SE functions should be centralized, which should be distributed, how much SE every engineer should know.
- Assessing Systems Engineering Performance of Business and Enterprises describes how a business understands how well it is doing with respect to the SE actually being performed using the techniques described in Systems Engineering and Management.
- Developing Systems Engineering Capabilities within Businesses and Enterprises describes how SE talent that delivers the desired SE capabilities is grown and acquired
- Barriers to Successful Embedding of Systems Engineering into Organizations describes the complexities surrounding the embedding of systems engineering into organizations.
- Finally, Culture describes how the culture of a business affects SE; e.g., a risk-averse business will likely use plan-driven SE processes; an entrepreneurial, fast-paced business will likely use agile SE processes (See Life Cycle Models).

To some extent, these topics have the character of a "plan-do-check-act" cycle, where the "do" part of the cycle is performing SE using the techniques described in Part 3, Systems Engineering and Management (Deming Part 3). For example, if assessing the business' SE performance shows shortfalls, then additional SE capabilities may need to be developed, the organization may need to be adjusted, processes may need to be improved, etc., all working within the existing cultural norms. If those norms prevent the business from successfully performing SE, then transformational efforts to change the culture may be needed as well.

Systems Engineering Organizational Strategy

- Lead Authors:
- Alice Squires, Dick Fairley, and Hillary Sillitto
- Contributing Authors:
- Art Pyster, Alan Faisandier, Deva Henry, and Rick Adcock

-

Virtually every significant business or enterprise that creates products or services benefits from performing a wide variety of systems engineering (SE) activities to increase the value that those products and services deliver to its owners, customers, employees, regulators, and other stakeholders. (See Stakeholder Needs Definition.)

A business is a specific type of enterprise, usually a legal entity with a management structure that allows for relatively tight control of its components, including how it enables SE. The term business is often used in this article in lieu of enterprise because specific actions to enable SE are typically done by businesses. This is discussed further in the parent article Enabling Systems Engineering. The strategy for organizing to conduct SE activities is important to their effectiveness. For example, every enterprise has a purpose, context, and scope determined by some of its stakeholders and modified over time to increase the value the enterprise offers to them.

Some enterprises are for-profit businesses. Others are not-for-profit businesses that work for the public good. Still others are non-traditional businesses, but more loosely structured entities without legal structure, such as a national healthcare system. Some enterprises are located at a single site, while some others are far-flung global "empires". Some work in highly regulated industries such as medical equipment, while others work with little government oversight and can follow a much wider range of business practices. All these variations shape the strategy for performing SE.

Primary Considerations

SE organizational strategy is driven by the goals of the business and the resources and constraints available to achieve those goals. SE strategy in particular is influenced by several considerations:

- The purpose of the business
- The value the business offers its stakeholders; e.g., profits, public safety, entertainment, or convenience
- The characteristics of the system which the SE activities support; e.g., the size, complexity, primary design factors, major components, required products, critical specialties, or areas of life cycle
- The phases of the life cycle in which the SE activities are being performed; e.g., development, deployment, operations, or maintenance of a product or service
- The scale of the business, the systems and services of interest; e.g., is it a single site company or a global venture? Is the business creating a relatively modest product for internal use, such as a new Web application to track employee training, or a new hybrid automobile complete with concerns for engineering, manufacturing, servicing, and distribution?
- The culture of the business in which the SE activities are performed; e.g., is the business risk-averse? Do people normally collaborate or work in isolated organizations?
- The business structure and how well the current structure aligns with what is needed to create new products and services; e.g., does the structure of the business align with the architecture of its major products and services?
- The degree of change or transformation that the business is undertaking in its operation, products, and markets

Rouse (2006) offers a thorough look at enterprise strategy, especially as it relates to delivering value to the enterprise in various phases of the life cycle, beginning with research and development through operations. Rouse provides a number of techniques to determine and improve the value offered to enterprises using SE methods, especially useful when an enterprise is undergoing significant transformation rather than conducting "business as usual"; e.g., the enterprise could be trying to:

- do current business better (drive down costs or improve quality of its current products and services);
- cope with a disruption in the market, a competitive threat, or changing customer expectations and ways of doing business;
- reposition itself in its value chain (move from being a part supplier to a subassembly supplier); or
- launch a new generation product or enter a new market.

Eisner (2008) provides a thorough look at different SE organizational approaches.

Systems Engineering Strategy Elements

Based on the primary considerations, the SE strategy generally addresses the following:

- How SE activities provide value to the business (See Economic Value of Systems Engineering)
- How SE activities are allocated among the various business entities (See Organizing Business and Enterprises to Perform Systems Engineering)
- What competencies are expected from the parts of the business in order to perform these SE activities (See Deciding on Desired Systems Engineering Capabilities within Businesses and Enterprises)
- How parts of the business gain and improve competencies (See Developing Systems Engineering Capabilities within Businesses and Enterprises)
- Who performs SE activities within each part of the business (See Team Capability)
- How people who perform SE activities interact with others in the business ((See Part 6: Related Disciplines)
- How SE activities enable the business to address transformation (See Enterprise Systems Engineering).

Depending on the business' approach to SE, there may not be a single coherent SE strategy common across the business. Different business units may have their own SE strategies, or development of a strategy may be delegated to individual projects. The SE strategy may not even be explicitly documented or may only be found in multiple

documents across the business. Some businesses publish guidebooks and policies that describe their organizational strategy. These are usually proprietary unless the business is a government or quasi-government agency. Two public documents are NASA (2007) and MITRE (2012). The latter has a number of short articles on different topics including an article on Stakeholder Assessment and Management and another on Formulation of Organizational Transformation Strategies.

Product and Service Development Models

There are three basic product and service development models that most businesses employ:

1. Market-driven commercial
2. Product-line
3. Contract

The biggest differences between the three business models are where requirements risks lie and how user needs and usage are fed into the design and delivery process. SE support to the business varies in each case.

Market-driven commercial products and services are sold to many customers and are typically developed by organizations at their own risk. The requirements come from marketing based on understanding the market, relevant regulation and legislation, and good ideas from within the organization (Pugh 1991, Smith and Reinertsen 1997). Sillitto (1999) contends that market-driven commercial product development is a form of systems engineering with adapted techniques for requirements elicitation and validation.

Product-line products and services are variants of the same product and service, usually customized for each customer. Extra investment is required to create the underlying product platform. Architecting such a platform in a way that supports cost-effective customization is usually more complex both technically and organizationally than market-driven commercial products and services.

Systems engineers typically play a central role in establishing the platform architecture, understanding the implications of platform choices on manufacturing and service, etc. There are a number of examples of good practices in product-line products and services; e.g., automobile models from virtually all major manufacturers such as Toyota, General Motors, and Hyundai; Boeing and Airbus aircraft such as the B-737 family and the Airbus 320 family; and Nokia and Motorola cellphones. The Software Engineering Institute has done extensive research on product lines for software systems and has developed a framework for constructing and analyzing them (Northrop et al. 2007). For a reference on product line principles and methods, see Simpson (et al. 2006).

Contract products and services often demand tailor-made system/service solutions which are typically specified by a single customer to whom the solution is provided. The supplier responds with proposed solutions. This style of development is common in defense, space, transport, energy, and civil infrastructure. Customers that acquire many systems often have a specific procurement organization with precise rules and controls on the acquisition process, and mandated technical and process standards. The supplier typically has much less flexibility in SE process, tools, and practices in this model than the other two.

Any single business or enterprise is likely to apply some combination of these three models with varying importance given to one or more of them.

Organizations That Use and Provide SE

There are five basic types of organizations that use SE or provide SE services:

1. A business with multiple project teams
2. A project that spans multiple businesses
3. An SE team within either of the above
4. A business with a single project team
5. An SE service supplier that offers a specific SE capability or service (tools, training, lifecycle process) to multiple clients, either as an external consultancy or as an internal SE function

The kind of business determines the scope and diversity of SE across the organization. This is shown in abstract form in Figure 1, which illustrates the fundamental form of an extended enterprise. This also shows how organizational structure tends to match system structure.

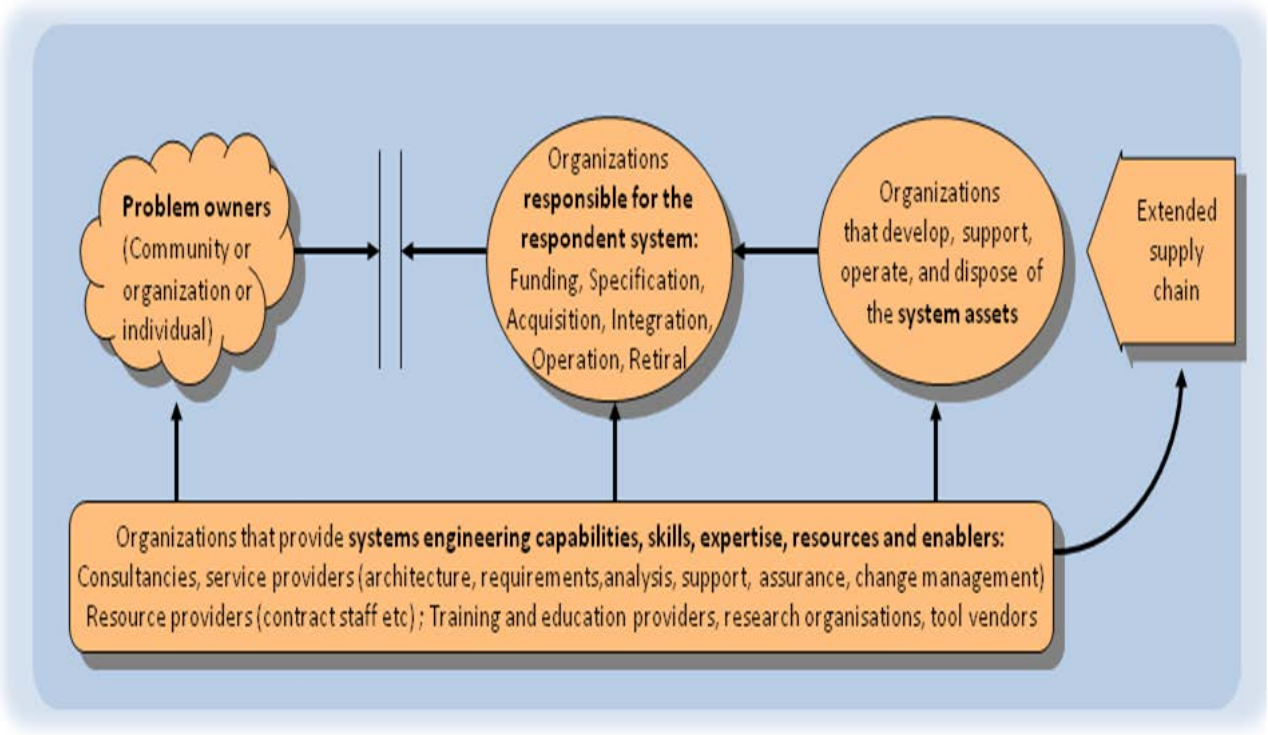

Figure 1. Organization Coupling Diagram. (SEBoK Original (Adapted from Lawson 2010))

The *problem owners* are the people, communities, or organizations involved in and affected by the *problem situation*. They may be seeking to defend a country, to improve transportation links in a community, or to deal with an environmental challenge. The *respondent system* might be a new fighter aircraft, a new or improved transportation infrastructure, or a new low-emission electricity generation systems (respectively). The organizations responsible for the respondent systems would be the Air Force, transport operator or regulator, or electricity supply company. The prime role of these organizations would be to operate the systems of interest to deliver value to the problem owners. They might reasonably be expected to manage the entire system lifecycle.

This same concept is expanded in Figure 2.

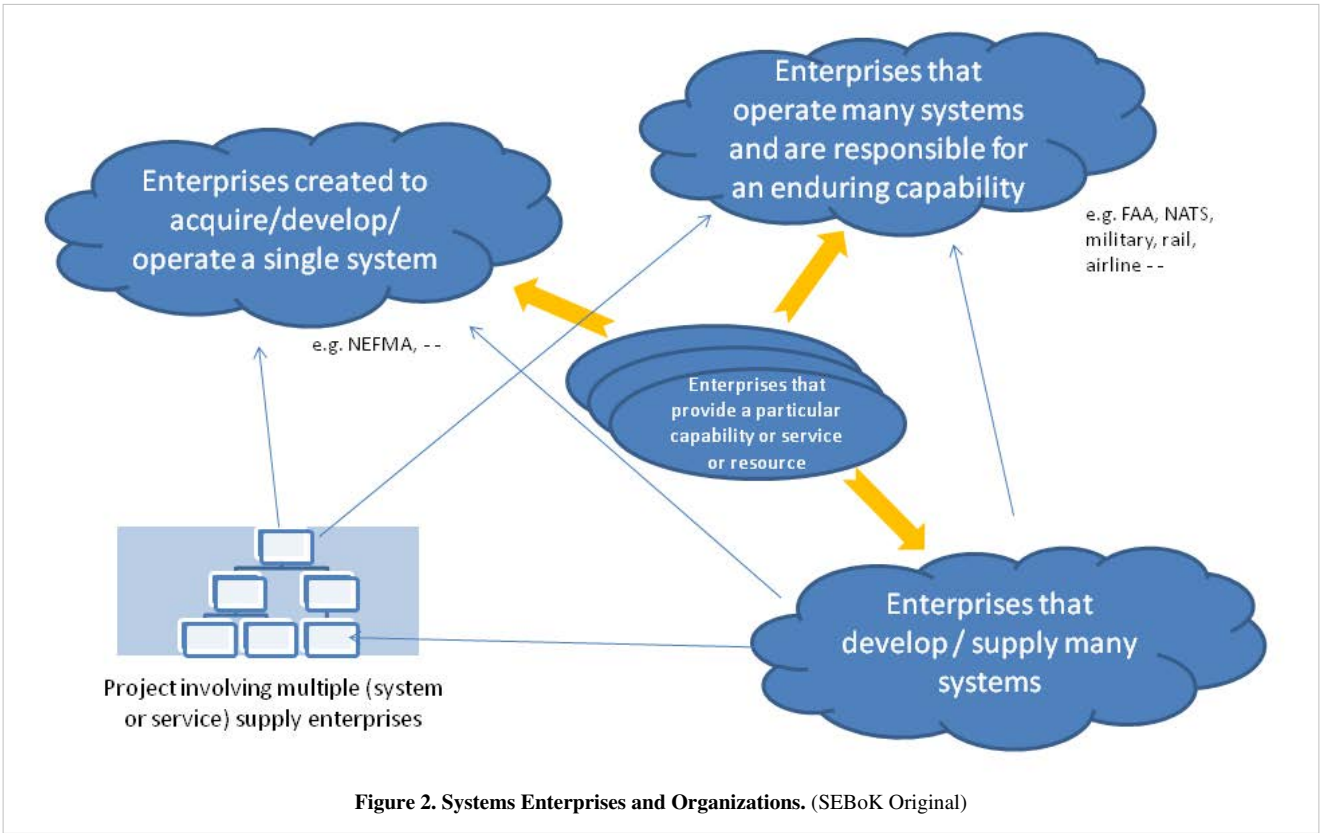

Figure 2. Systems Enterprises and Organizations. (SEBoK Original)

Goals, Measures, and Alignment in a Business

The alignment of goals and measures within the business strongly affects the effectiveness of SE and the benefit delivered by SE to the business, and needs to be carefully understood:

- Blockley and Godfrey (2000) describe techniques used successfully to deliver a major infrastructure contract on time and within budget, in an industry normally plagued by adversarial behavior.
- Lean thinking provides a powerful technique for aligning purpose to customer value – provided the enterprise boundary is chosen correctly and considers the whole value stream (Womack and Jones 2003; Oppenheim et al. 2010).
- Fasser and Brettner (2002, 18-19) see an organization as a system, and advocate three principles for organizational design: (1) increasing value for the ultimate customer, (2) strict discipline, and (3) simplicity.
- EIA 632 (ANSI/EIA 2003) advocates managing all the aspects required for the life cycle success of each element of the system as an integrated "building block". Similarly, Blockley (2010) suggests that taking a holistic view of *"a system as a process"* allows a more coherent and more successful approach to organization and system design, considering each element both as part of a bigger system-of-interest and as a "whole system" (a "holon") in its own right.
- Elliott et al. (2007) advocate six guiding principles for making systems that work: (1) debate, define, revise and pursue the purpose, (2) think holistically, (3) follow a systematic procedure, (4) be creative, (5) take account of the people, and (6) manage the project and the relationships.
- For organizations new to SE, the INCOSE UK Chapter has published a range of one-page guides on the subject, including Farncombe and Woodcock (2009a; 2009b).

Governance

SE governance is the process and practice through which a business puts in place the decision rights that enable SE to deliver as much business value as possible. Those rights may be codified in policy, implemented through the business structure, enforced through tools, and understood through measures of compliance and effectiveness.

SE governance in large businesses is often explicit and codified in policy. In small businesses, it is often tacit and simply understood in how the business works. One of the key implementation steps when a business defines its SE strategy is to establish its SE governance model, which should be tailored to the particular context in which the business operates and delivers value. Of course, in practice, this is often incremental, uneven and subject to wide swings based on the current state of the business and the people occupying key management positions.

The term governance for development organizations was first popularized in reference to how Information Technology (IT) is overseen in businesses and enterprises (Weill and Ross 2006; Cantor and Sanders 2007). The recognition in the 1990s and the last decade that IT is a fundamental driver of performance and value for most corporations and government agencies led to the transformation of the Chief Information Officer (CIO) into a key senior manager.

Explicit governance of IT became important to enabling an enterprise to respond to new technology opportunities, emerging markets, new threats, and rapid delivery of new products and services. The term "governance" is now widely used to describe how SE is woven into an enterprise. Governance becomes especially challenging for complex projects in which there are high levels of uncertainty (Cantor 2006) or for system of systems projects in which responsibility for major decisions may be distributed over multiple organizations within an enterprise in which there is no single individual who is "in control" (see Systems of Systems (SoS)). Morgan and Liker (2006) describe the governance model for Toyota, which is one of the largest companies in the world.

SE governance establishes the framework and responsibility for managing issues such as design authority, funding and approvals, project initiation and termination, as well as the legal and regulatory framework in which the system will be developed and will operate. Governance includes the rationale and rules for why and how the enterprise policies, processes, methods and tools are tailored to the context. SE governance may also specify product and process measures, documentation standards, and technical reviews and audits.

The ways in which a team organizes to conduct SE activities either conform to policies established at the level above or are captured in that team's own governance policies, processes, and practices. These policies cover the organizational context and goals, the responsibilities for governance, process, practices and product at the level of interest, and the freedom delegated to and governance and reporting obligations imposed on lower organizational levels. It is good practice to capture the assignment of people and their roles and responsibilities in the form of the Responsible, Accountable, Consult, Inform (RACI) matrix (PMI 2013) or something similar. Responsibility in large organizations can easily become diffused. Sommerville et al. (2009, 515-529) discuss the relationship between information and responsibility, and describe methods to analyze and model responsibility in complex organizations.

Small organizations tend to have relatively informal governance documentation and processes, while larger organizations tend towards more structure and rigor in their governance approach. Government organizations responsible for developing or acquiring large complex systems, such as the US Department of Defense or the US Federal Aviation Administration, usually develop policies that describe governance of their SE activities and SE organizations. See DoD (2012) for the Department of Defense SE policies.

Government contracting typically brings additional regulation and oversight, driving a group to greater rigor, documentation, and specific practices in their SE governance. Development of systems or operating services that affect public safety or security is subject to constraints similar to those seen in government contracting. Think of the creation of medical devices or the operation of emergency response systems, air traffic management, or the nuclear industry. (See Jackson (2010) for example).

Governance models vary widely. For example, Linux, the greatest success of the open source community, has a governance model that is dramatically different than those of traditional businesses. Smith (2009) offers a cogent explanation of how decisions are made on what goes into the Linux kernel. All of the decision rights are completely transparent, posted on the Linux website, and have proven remarkably effective as they have evolved. The classic paper *The Cathedral and The Bazaar* by Eric Raymond (2000) provides great insight into the evolution of Linux governance and how Linus Torvalds responded to changing context and circumstances to keep Linux so successful in the marketplace with a governance model that was radically novel for its time.

The project management literature also contributes to the understanding of SE governance (see Systems Engineering and Project Management). For example, Shenhar and Dvir (2007) offer the "diamond model" for project management, which identifies four dimensions that should guide how development projects are managed: novelty, technology, complexity, and pace. Application of this model to SE governance would influence the available life cycle models for development projects and how those models are applied.

There are numerous examples of projects that went well or badly based largely on the governance practiced by both the acquirer and the supplier organizations. Part 7 of the SEBoK has several examples, notably Singapore Water Management (went well) and FAA Advanced Automation System (AAS) (went less well).

Determining Needed Systems Engineering Capabilities in Businesses and Enterprises

- Lead Authors:
- Richard Beasley, Hillary Sillitto, and Scott Jackson
- Contributing Authors:
- Alice Squires, Heidi Davidz, Garry Roedler, Richard Turner, Art Pyster, and Ray Madachy

-

Enabling a business or enterprise to perform systems engineering (SE) well requires deciding which specific SE capabilities the business or enterprise needs in order to be successful. (In the rest of this article business or enterprise is usually abbreviated to just "business", because a business is a specific type of enterprise that has sufficiently strong central authority and motivation to take steps to enable SE). SE capabilities should support the Systems Engineering Organizational Strategy and reflect the nature of the business, its products and services, various stakeholders, business leadership focus, etc.

This topic, which is part of the Enabling Businesses and Enterprises knowledge area (KA) of Part 5, summarizes the factors used to decide which SE capabilities a business needs; e.g., the interactions between SE and other functional areas in the business, and consideration of social dynamics and leadership at the team and business levels. Needed capabilities may be decided and developed centrally by a business, or within teams and by individuals, or through some combination of the two. Determination of team SE capability is discussed in the article Team Capability, and individual SE competencies are discussed in the article Roles and Competencies.

Relationship of this Topic to Enterprise Systems Engineering

Enterprise Systems Engineering and Capability Engineering techniques can be used to establish needed SE capabilities. At a high level of abstraction, the following are basic steps that could be used to decide the desired SE capabilities within the business:

1. understand the context;
2. determine the required SE roles;
3. determine the competencies and capabilities needed for each of the SE roles;
4. assess the ability and availability of the needed SE organizations, teams, and individuals;
5. adjust the required SE roles based on the actual ability and availability; and
6. organize the SE function to facilitate communication, coordination, and performance.

See the article Organizing Business and Enterprises to Perform Systems Engineering for additional information. More information on context and required SE roles is provided below.

Contextual Drivers

The following discussion illustrates some of the contextual factors that influence the definition of the SE capability needed by a business.

Where the SE Activities are Performed in the Value Chain

The SE approach adopted by the business should depend on what role the organization plays. Ring (2002) defines a value cycle, and where the business sits in that cycle is a key influence of SE capability need.

- **Problem owner:** focus on identifying and scoping the system problem (defining system-of-interest (SoI))and understanding the nature of the appropriate respondent system using Enterprise Systems Engineering and Capability Engineering approaches.
- **System operator:** focus on establishing all the necessary components of capability to deliver the required services, as well as on integrating new system assets into the system operation as they become available (see Service Systems Engineering). The definition of the components of capability varies by organization - e.g.,
  - The US Department of Defense defines the components of capability as DOTMLPF: doctrine, organization, training, materiel, logistics, people, and facilities.
  - The UK Ministry of Defense defines the components of capability as TEPIDOIL; i.e., training, equipment, people, information, doctrine, organization, infrastructure, and logistics.
  - Other domains and organizations define the components of capability with similar, equivalent breakdowns which are either explicit or implicit.
- **Prime contractor or primary commercial developer:** focus on understanding customer needs and trading alternative solution approaches, then establishing a system team and supply chain to develop, deliver, support, and in some cases, operate the system solution. This may require enterprise SE (see Enterprise Systems Engineering) as well as "traditional" product SE (see Product Systems Engineering).
- **Subsystem/component developer:** focus on understanding the critical customer and system integrator issues for the subsystem or component of interest, defining the component or subsystem boundary, and integrating critical technologies. This may exploit re-usable elements and can be sold in identical or modified forms to several customers. (In Part 4 of the SEBoK, see Systems of Systems, Enterprise Systems Engineering, and Product Systems Engineering for more information and references to the literature.)
- **Specialist service provider:** focus on specific process capabilities and competences which are typically sold on a time and materials or work package basis to other businesses.

Where the Enterprise Operates in the Lifecycle

The SE capabilities required by the business will depend on the system life cycle phase(s) in which it operates (see Life Cycle Models in Part 3).

- **Concept definition phase:** requires the SE capability to identify a “problem situation,” define the context and potential concept of operations for a solution system, assess the feasibility of a range of possible solutions in broad terms, and refine the definition to allow the development of system requirements for the solution (see System Concept Definition in Part 3).
- **System Definition phase:** requires the SE capability to influence concept studies (ensure feasible and understood by the development team), establish the trade space that remains at the end of the concept study, perform the system definition activities, including architecture design, and create a detailed definition of the system elements.
- **System realization phase:** requires the SE capability to configure the manufacturing and logistics systems for the system assets, and manufacture system assets (see System Realization in Part 3).
- **System deployment and use:** requires the SE capability to maintain business continuity during the transition to operation, bring the system into service, support system, monitor system performance, and respond to emerging needs (see System Deployment and Use). Elliott et al. (2008) describe the different emphases that should be

placed in SE during the "in-service" phase. This phase particularly requires the business to be able to perform SE at an appropriate operational tempo.

- **Retirement phase:** requires the SE capability for ensuring the safe retirement of systems and keeping them in a state ready for re-activation (“mothballed”), safe disposal of the system assets.

Nature of Responsibility to End Users and Society

Depending on the business model and the contracting environment, the business may find that its responsibility to end users is:

- **explicit**, or spelled out by clear requirements and prescriptive legislation; or
- **implicit**; i.e., a legal or ethical obligation to ensure “fitness for purpose” which may be enforced by commercial frameworks, national or international standards, and specific product liability legislation.

Typically, businesses whose business model is contract driven focus on satisfying explicit requirements, whereas market-driven businesses must be more aware of implicit responsibilities.

Nature of Responsibility to Customers

The business may contract with its customers to deliver any of the following:

- **an outcome**: The intended benefits the system is expected to provide, requires enterprise systems engineering;
- **an output**: Deliver or operate the system or part of it against agreed acceptance criteria; requires product systems engineering;
- **an activity**: Perform a specified set of tasks, requires service systems engineering; and
- **a resource**: Provide a specified resource; requires focus on individual competencies - see Enabling Individuals.

Scale of Systems

The business or enterprise may need very different SE approaches depending on the scale of the system at which the business operates. The following categories are based on Hitchins’ five layered system model (Hitchins 2005):

- **Level 1: Subsystem and technical artifacts –** focus on product systems engineering and on technology integration.
- **Level 2: Project systems –** focus on product systems engineering with cross-discipline and human integration.
- **Level 3: Business systems –** focus on enterprise systems engineering , service systems engineering to implement them, and on service management (Chang 2010) and continuous improvement (SEI 2010b); see also Quality Management) for the day to day running of the business.
- **Level 4: Industry systems –** If there is a conscious effort to treat an entire industry as a system, the focus will be on Enterprise Systems Engineering, and on the long-term economic and environmental sustainability of the overall industry.
- **Level 5: Societal systems –** Enterprise systems engineering is used to analyze and attempt to optimize societal systems (see Singapore Water Management in Part 7).

Sillitto (2011) has proposed extending this model to cover sustainability issues by adding two additional layers, the “ecosystem” and the “geosystem”.

Complexity of Systems Integration Tasks and Stupples' levels

Creating Systems That Work – Principles of Engineering Systems for The 21st century identifies three "kinds" of SE, originally proposed by Stupples (2006), that have to do with the level of cross-disciplinary integration involved (Elliot et al. 2007).

1. Within a discipline (e.g., software, hardware, optics, *or* mechanics), the SE focus is on taking a systems view of the architecture and implementation to manage complexity and scale within a single engineering discipline.
2. In multiple disciplines (e.g., software, hardware, optics, *and* mechanics), the SE focus is on holistic integration of multiple technologies and skills to achieve a balanced system solution.
3. In socio-technical systems integration, the SE focus is on getting people and the non-human parts of the system working synergistically.

Sillitto (2011) proposed extending this model properly to cover sustainability issues by adding one additional level, "Environmental Integration". He describes this level and show how the Stupples' levels relate to other dimensions used to categorize systems and professional engineering skills.

Criticality of System and Certification Requirements

The level of rigor in the SE approach adopted by the business will depend on the criticality of various classes of requirement. (See Systems Engineering and Specialty Engineering.)

- Safety and security requirements often demand specific auditable processes and proof of staff competence.
- Ethical and environmental requirements may require an audit of the whole supply and value chain.
- Extremely demanding combinations of performance requirements will require more design iteration and more critical control of component characteristics; e.g., see Quality Management and *Management for Quality in High-Technology Enterprises* (Fasser and Brettner 2010).

The Nature of a Contract or Agreement

The nature of the contractual relationship between a business and its customers and end users will influence the style of SE.

- Fixed price, cost plus, or other contracting models influence the mix of focus on performance and cost control and how the business is incentivized to handle risk and opportunity.
- In mandated work share arrangements, the architecture of the product system may be compromised or constrained by the architecture of a viable business system; this is often the case in multi-national projects and high-profile government procurements (Maier and Rechtin 2009, 361-373).
- In self-funded approaches, the priorities will be requirements elicitation approaches designed to discover the latent needs of consumers and business customers, as well as development approaches designed to achieve rapid time to market with a competitive offering, or to have a competitive offering of sufficient maturity available at the most critical time during a customer's selection process.
- In single phase or whole-life approaches, the business may be able to optimize trade-offs across the development, implementation, and in-service budgets, and between the different components of capability.

The Nature and Predictability of Problem Domain(s)

Well-defined and slowly changing technologies, products, and services permit the use of traditional SE life cycle models based on the waterfall model because the requirements risk and change is expected to be low (see Life Cycle Models).

Poorly defined and rapidly changing problem domains, with operators subject to unpredictable and evolving threats, demand more flexible solutions and agile processes. SE should focus on modular architectures that allow rapid reconfiguration of systems and systems-of-systems, as well as rapid deployment of new technologies at a subsystem level to meet new demands and threats.

Fundamental Risks and Design Drivers in the Solution Domain

When the solution domain is stable, with a low rate of technology evolution, and systems use mature technology, the focus is on optimum packaging and configuration of known and usually well-proven building blocks within known reference architectures, and on low-risk incremental improvement over time.

When there is rapid technology evolution, with pressure to bring new technologies rapidly to market and/or into operational use, the SE approach has to focus on technology maturation, proof of technology and integration readiness, and handling the technology risk in the transition from the lab to the proof of concept to the operational system.

There is usually a trade-off between lead time expectations and the level of integrity/certification. In the development of new systems, short lead times are seldom compatible with high levels of system integrity and rigorous certification.

Competitive Situation and Business Goals

The business drivers for SE deployment may be one or more of the following:

- To perform existing business better;
- To recover from a competitive shock or a shift in clients' expectations;
- To develop a new generation product or service;
- To enter a new market; and/or
- To reposition the business or enterprise in the value chain.

In the first case, SE can be deployed incrementally in parts of the business process where early tangible benefits can be realized. This could be the early steps of a business-wide strategic plan for SE. (See Systems Engineering Organizational Strategy for more on setting SE strategy and Developing Systems Engineering Capabilities within Businesses and Enterprises for improving SE capabilities.)

In the other cases, the business is going through disruptive change and the early priority may be to use systems thinking (see Systems Thinking) and enterprise SE approaches to scope the transformation in the context of a major change initiative.

Type of System or Service

There are three distinct flavors of products or service types (see Systems Engineering Organizational Strategy):

1. In a product or productized service, the focus will be on predicting how the market might change during the development period, eliciting, anticipating, and balancing requirements from a variety of potential customers, and optimizing features and product attractiveness against cost and reliability.
2. In a custom solution (product or service) the focus will be on feasible and low-risk (usually) approaches to meet the stated requirement within budget, using system elements and technologies that are known or expected to be available within the desired development timescale.
3. Tailored solutions based on standard product and/or service elements require a much more sophisticated SE process that is able to use a "product line approach" to blend standard modules with planned adaptation to meet clients' specific needs more quickly and cheaply than would be possible with a single contract solution. The business needs to manage the life cycle and configuration of the standard modules separately from, but coherently with, the life cycle and configuration of each tailored solution.

Needed Systems Engineering Roles

After understanding the context for the business, the next step is to determine the SE capabilities required in the role in the business. The SEI Capability Maturity Models for acquisition, development, and services (SEI 2007; SEI 2010a; SEI 2010b) provide a framework for selecting SE capabilities relevant to different types of business. Existing SE competency models can be used to assist in determining the needed capabilities. An example is the INCOSE SE Competencies Framework (INCOSE 2010). (See Roles and Competencies for more information on competency models.)

The spread of SE focus can be a wide spectrum, from SE being focused in a specialist, interface or glue role (Sheard 1996), to the idea that "SE is good engineering with special areas of emphasis… including interfaces between disciplines" (Blanchard and Fabrycky 2005) and so it is shared by all. In any organization where activities and skills are shared, there is always a danger of silos or duplication.

As part of the role definition, the business must define where an individual doing SE fits into career progression (what roles before SE, what after?). Developing Individuals describes how individuals improve SE; the organization must define the means by which that development can be enacted. Businesses need to customize from a range of development strategies; see, for example, Davidz and Martin (2011).

As shown in Figure 1 below, management action on workforce development will be required if there are systemic mismatches between the competencies required to perform SE roles and the actual competencies of individuals. The organizational culture may have a positive or negative effect on team performance and the overall value added by the business (see Culture).

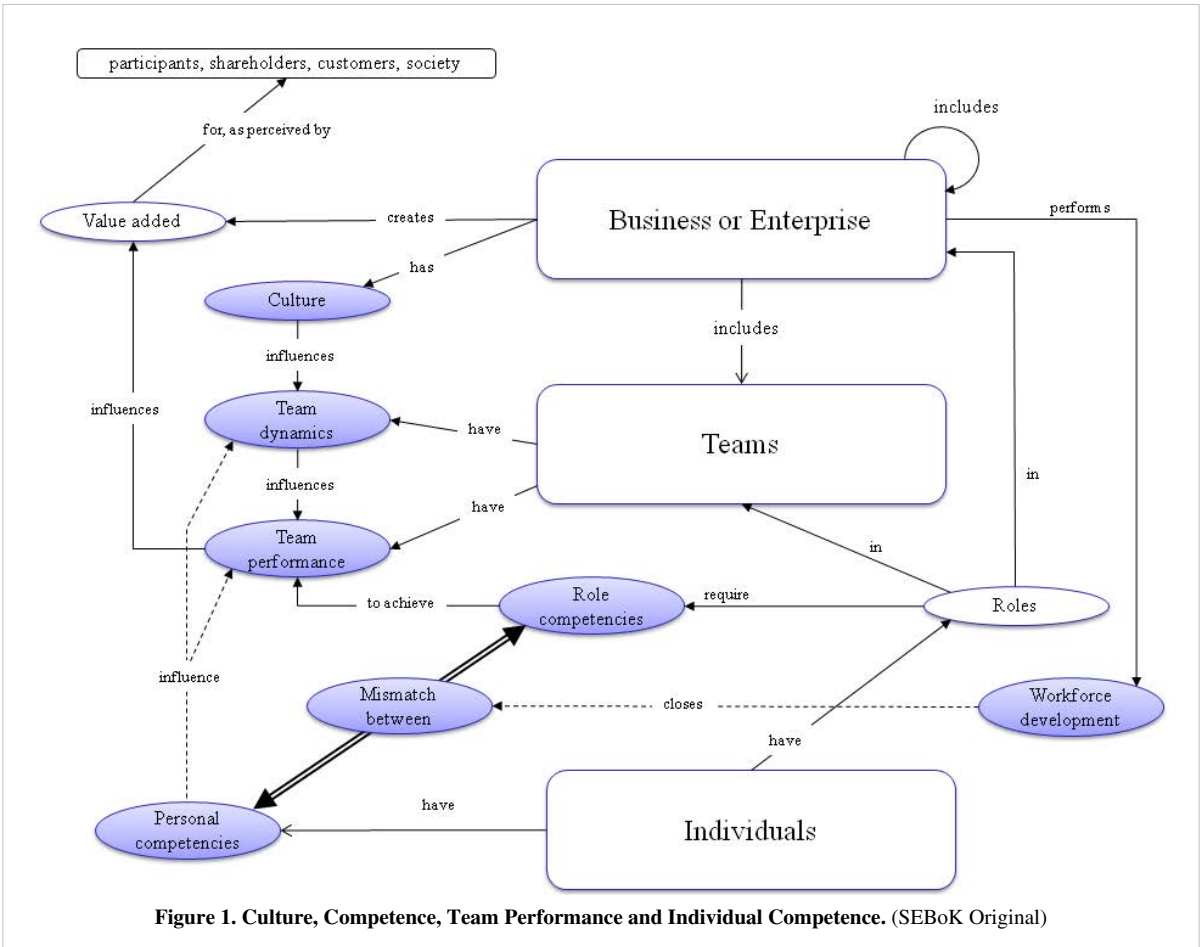

Figure 1. Culture, Competence, Team Performance and Individual Competence. (SEBoK Original)

Required SE Processes and Methods

The decisions on how to implement SE capability must be embedded in the businesses processes and its availability methodologies and toolsets. Embedding SE principles, processes, and methods in the organization's quality management system means that senior management and the quality system will help embed SE in the organizational business process and make sure it is applied (INCOSE 2012; ISO/IEC 2008; see Quality Management).

When defining the processes and tools, a balance between the need for a systematic and standardized approach to SE processes, such as that seen in INCOSE (2012), with the flexibility inherent in systemic thinking is critical. Systems thinking helps the organization understand problem situations, remove organizational barriers, and make the most of the organization's technical capabilities (see Beasley (2011)).

Need for Clarity in the SE Approach and the Dangers of Implementing SE

Clarity on how the organization performs SE is important. Typically, implementing SE may be part of an organization's improvement, so Kotter's principles on creating a vision, communicating the vision, and empowering others to act on the vision are extremely relevant (Kotter 1995). The way an organization chooses to perform SE should be part of the vision of the organization and must be understood and accepted by all.

Many of the major obstacles in SE deployment are cultural (see Culture).

One of the lean enablers for SE is to "pursue perfection" (Oppenheim et al. 2010). The means of improvement at a business or enterprise level are discussed in detail elsewhere, but the starting point must be deciding what SE capabilities the organization wants. It needs to be recognized that the needed capabilities change over time (learning, improving, or losing capability). Thus, balancing SE with everything else that it involves is an ever-changing

process.

Organizing Business and Enterprises to Perform Systems Engineering

- Lead Authors:
- Richard Beasley, Art Pyster, and Hillary Sillitto
- Contributing Authors:
- Alice Squires, Heidi Davidz, Scott Jackson, and Quong Wang

-

In order for a business or enterprise to perform systems engineering (SE) well, the team must decide which specific SE capabilities the business or enterprise needs in order to be successful and then organizing to deliver those capabilities. (In the rest of this article, business or enterprise is usually abbreviated to just "business", because a business is a specific type of enterprise that has sufficiently strong central authority and motivation to take steps to enable SE).

SE capabilities and organizational approach should support the Systems Engineering Organizational Strategy and reflect the nature of the business, its products and services, various stakeholders, business leadership focus, etc. This topic, which is part of Part 5, Enabling Businesses and Enterprises, summarizes the factors used to organize a business to perform SE.

Components of Business and Enterprise SE Capability

Organization Issues - Culture, Knowledge, Information, and Infrastructure

The way SE is managed is described in Systems Engineering Organizational Strategy, which both impacts and responds to the SE culture and approach.

Knowledge and Information

Knowledge and Information are key assets in a business, and their management is critical. Fasser and Brettner (2002) discuss knowledge management extensively. They assert that *"We may think that knowledge transfer is just an information technology issue, but in actuality, it is also a psychological, cultural, and managerial issue – in short a human issue" and "Only information in action can create knowledge".*

Organizations need to manage SE know-how, integration of SE with other organizational processes and activities, and knowledge of their business domain. The INCOSE Intelligent Enterprise Working Group's work on knowledge management in an SE context led to the publication of a *"Concept of Operations for a Systems Engineering Educational Community"* (Ring et al. 2004).

Information has to be both shared and protected in complex organizations. Sharing is key to effective collaboration and is constrained by the need to protect intellectual property, as well as commercially and nationally sensitive material. Different cultures and personal styles use information in different ways and in different orders. (Levels of abstraction, big picture first or detail, principles first or practical examples, etc.) Sillitto (2011b) describes the knowledge management challenges for large, multi-national organizations.

Projects need to manage project information and establish configuration control over formal contractual information, as well as the information that defines the product/service being developed, supplied, or operated. A key role of systems engineers is to "language the project" (Ring et al. 2004). Good data management and tool support will allow people to document once, use many times, and ensures consistency of information over time and between different teams.

System information needs to be maintained throughout the life of the system and made available to relevant stakeholders – including those designing new systems that must interface to the system-of-interest - to allow system management, maintenance, reconfiguration, upgrade and disposal, and forensics after accidents and near-misses. Elliott et al. (2008) suggest that information management is the dominant problem in SE in service systems, and that the cost and difficulty of establishing current state and legacy constraints before starting to implement a change is often underestimated.

"Infostructure" (information infrastructure) to support the system lifecycle will include the following:

- Information assets such as process libraries, document templates, preferred parts lists, component re-use libraries, as-specified and as-tested information about legacy systems, capitalized metrics for organizational performance on previous similar projects, all with appropriate configuration control
- Modeling and simulation tools, data sets and run-time environments
- Shared working environments – workspaces for co-located teams, areas for people to interact with each other to develop ideas and explore concepts, work areas suitable for analysis tasks, meeting rooms, access control provision, etc.
- IT facilities - computer file structures, software licenses, IT equipment, computer and wall displays to support collaborative working, printers, all with appropriate security provision and back-up facilities, procedures for efficient use, and acceptable performance and usability
- Security provisions to protect own, customer, supplier and third party IPR and enforce necessary protective working practices while allowing efficient access to information for those with a need to know

SE is a knowledge activity. Systems engineers need appropriate facilities for accessing, sharing and capturing knowledge, as well as for interacting effectively with the whole set of stakeholders. Warfield (2006) describes collaborative workspaces, environments and processes for developing a shared understanding of a problem situation.

Enabling Infrastructure

The ISO/IEC 15288 (ISO 2008) Infrastructure Management Process provides the enabling infrastructure and services to support organization and project objectives throughout the life cycle. Infrastructure to support the system life cycle will often include the following:

- Integration and test environment – bench and lab facilities, facilities for development testing as well as acceptance testing at various levels of integration, calibration and configuration management of test environments
- Trials and validation environment – access to test ranges, test tracks, calibrated targets, support and storage for trials – equipment, harbor, airfield and road facilities, safe storage for fuel, ordinance, etc.
- Training and support infrastructure – training simulators, embedded training, tools and test equipment for operational support and maintenance, etc.

People

The roles people fill are typically defined by the business/enterprise (see Determining Needed Systems Engineering Capabilities in Businesses and Enterprises), although those decisions may be pushed down to teams. Enabling Teams explains how people are used in teams; Enabling Individuals describes the development of an individual's SE competence.

The implementation of these roles needs further consideration. Sheard (1996) lists twelve system engineering roles. Sheard (2000) draws an important distinction between roles involved in the discovery phase, characterized by a high level of uncertainty, the program phase, which is more deterministic and defined, and the overall systems engineering approach. Kasser et al. (2009) identify five types of systems engineer distinguished by the need to work at increasing levels of abstraction, ambiguity, scope and innovation. Sillitto (2011a) discusses a number of SE roles and the characteristics required of them, in the context of the wider engineering and business professional landscape.

Systems engineering exists within an enterprise “ecosystem.” Two key aspects to consider:

- How much should the business/enterprise nurture and value the systems engineer?
- How much should the business/enterprise pull value from systems engineers, rather than wait for systems engineers to "push" value on the business/enterprise?

Process

Many SE organizations maintain a set of organizational standard processes which are integrated in their quality and business management system, adapted to their business, and with tailoring guidelines used to help projects apply the standard processes to their unique circumstances. Guidance on organizational process management is provided by such frameworks as the Capability Maturity Model Integration (CMMI) (SEI 2010), which has two process areas on organizational process: Organizational Process Development (OPD) is concerned with organizational definition and tailoring of the SE lifecycle processes (discussed in detail elsewhere in this document) and Organizational Process Focus (OPF), which is concerned with establishing a process culture in an organization.

To document, assess, and improve SE processes, businesses often establish a systems engineering process group. Members of such groups often create standard process assets and may mentor teams and business units on how to adopt those standard processes and assess how effective those processes are working. There is a large body of literature on SE process improvement based on various process improvement models. Two of the most popular are ISO/IEC 9000 (2000) and CMMI (SEI 2010). The Software Engineering Institute, which created the CMMI, offers many free technical reports and other documents on CMMI at http://www.sei.cmu.edu/cmmi.

Assessment and measuring process performance is covered in Assessing Systems Engineering Performance of Business and Enterprises.

Tools and Methods

SE organizations often invest in SE tools and models, develop their own, and/or integrate off-the-shelf tools into their particular business/enterprise processes. Tools require great attention to culture and training; to developing a consistent "style" of use so that people can understand each others' work; and proper configuration and management of the information so that people are working on common and correct information.

It is important that methods are used as well as tools, particularly to support Systems Thinking.

It is common practice in large SE organizations to have a tool support infrastructure which ensures that tools support the organizational standard processes and are fully integrated with training, and that projects and teams can use the tools to do their job and are not distracted by tool management issues that are more efficiently handled centrally. Smaller SE organizations often operate more informally.

Fitting It All Together

The concept map in Figure 1 below shows the relationships between the various aspects of organization, resource, responsibility, and governance.

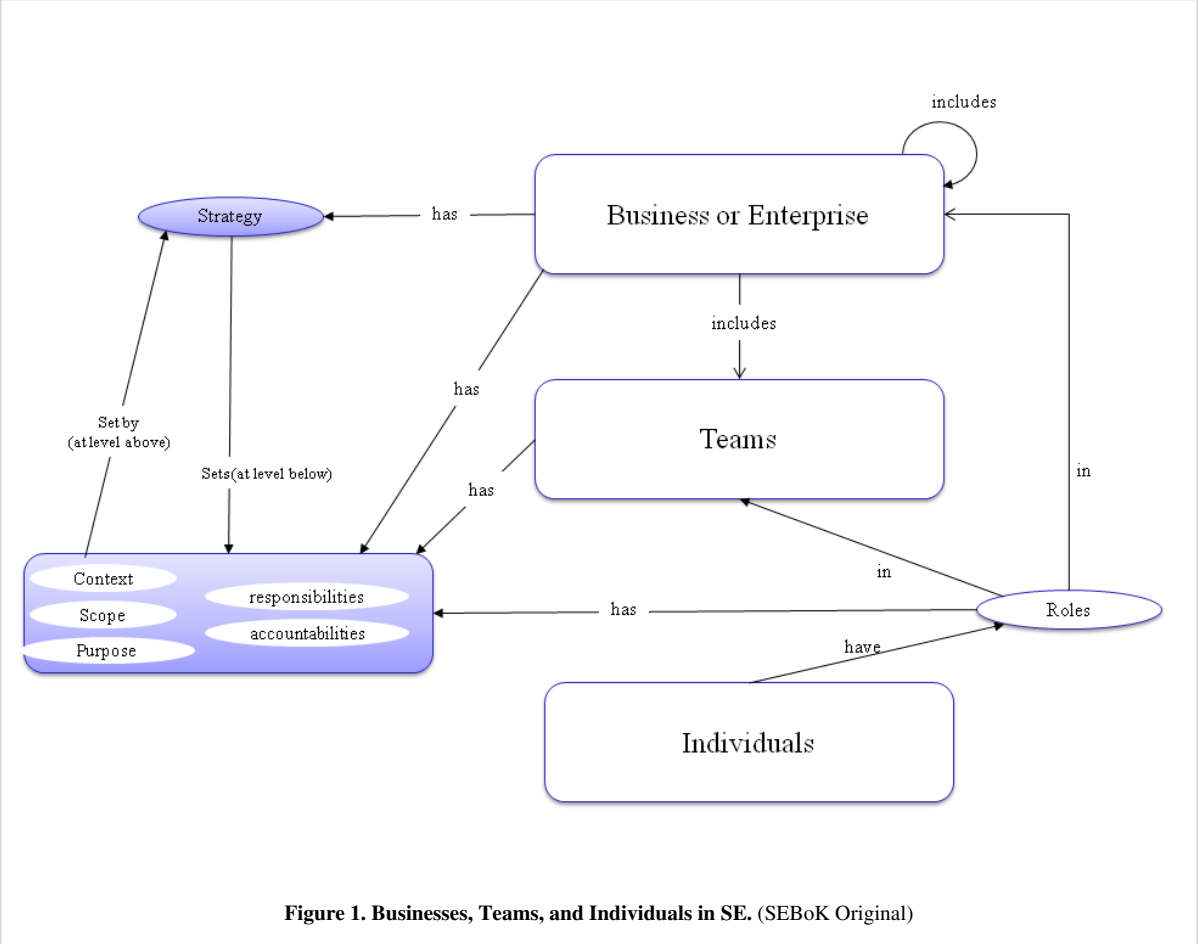

Figure 1. Businesses, Teams, and Individuals in SE. (SEBoK Original)

Enterprise Structures and Their Effects on SE

Enterprises manage SE resources in many different ways. A key driver is the extent to which they seek to optimize use of resources (people, knowledge, and assets) across teams and across the enterprise as a whole. Five common ways of organizing resources to support multiple projects are: project; matrix; functional; integrated; and product centered (CM Guide 2009, Handy 1985, PMI 2013, section 2.1.3). A large enterprise would likely apply some combination of these five ways across its constituent sub-enterprises and teams. Browning (2009) offers a way to optimize project organizational structure. Eisner (2008) offers a good overview of different organizational models.

Project Organization

A project organization is one extreme in which projects are responsible for hiring, training, and terminating staff, as well as managing all assets required for delivery. In this model, systems engineers on a project report to the project manager and resources are optimized for the delivery of the project. This model has the advantage of strongly aligning the authority and responsibility of the project with the project manager. However, it operates at the expense of sub-optimizing how the staff is deployed across the larger enterprise, how technology choices are made across projects, etc. *Systems Engineering Fundamentals* (DAU 2001) offers a DoD view of good practice project organizations.

Functional Organization

A functional organization demonstrates the opposite extreme. In a functional organization, projects delegate almost all their work to functional groups, such as the software group, the radar group or the communications group. This is appropriate when the functional skill is fast-evolving and dependent on complex infrastructure. This method is often used for manufacturing, test engineering, software development, financial, purchasing, commercial, and legal functions.

Matrix Organization

A matrix organization is used to give systems engineers a “home” between project assignments. Typically, a SE functional lead is responsible for career development of the systems engineers in the organization, a factor that influences the diversity and length of individual project assignments.

Integrated Organization

In an integrated organization, people do assigned jobs without specific functional allegiance. Those that perform SE tasks are primarily identified as another type of engineer, such as a civil or electrical engineer. They know systems engineering and use it in their daily activities as required.

Product Centered Organization

In accordance with the heuristic that “the product and the process must match” (Rechtin 1991, 132), a common method for creating an organizational structure is to make it match the system breakdown structure (SBS). According to Browning (2009), at each element of the SBS there is an assigned integrated product team (IPT). Each IPT consists of members of the technical disciplines needed to design the product system. The purpose of the IPT is to assure that the interactions among all the technical disciplines are accounted for in the design and that undesirable interactions are avoided.

Interface to Other Organizations

Outside official engineering and SE organizations within an enterprise, there are other organizations whose charter is not technical. Nevertheless, these organizations have an important SE role.

- **Customer Interface Organizations:** These are organizations with titles such as Marketing and Customer Engineering. They have the most direct interface with current or potential clientele. Their role is to determine customer needs and communicate these needs to the SE organization for conversion to product requirements and other system requirements. Kossiakoff and Sweet (2003, 173) discuss the importance of understanding customer needs.
- **Contracts Organizations:** These organizations interface with both customer and supplier organizations. Their role is to develop clearly stated contracts for the developer or the supplier. These contracts convey tasks and responsibilities for all SE roles of all parties. Technical specifications are attached to the contracts. Responsibilities for verification and validation are specified.
- **Supplier Management Organizations:** These organizations are responsible for selecting and managing suppliers and assuring that both contractual and technical products are in place. These organizations balance cost and risk to assure that supplier products are delivered, verified, and validated for quality product. Blanchard and Fabrycky (2005, 696-698) discuss the importance of supplier selection and agreement.

Assessing Systems Engineering Performance of Business and Enterprises

- Lead Authors:
- Hillary Sillitto, Alice Squires, and Heidi Davidz
- Contributing Authors:
- Art Pyster and Richard Beasley

-

At the project level, systems engineering (SE) measurement focuses on indicators of project and system success that are relevant to the project and its stakeholders. At the enterprise level there are additional concerns. SE governance should ensure that the performance of systems engineering within the enterprise adds value to the organization, is aligned to the organization's purpose, and implements the relevant parts of the organization's strategy.

For enterprises that are traditional businesses this is easier, because such organizations typically have more control levers than more loosely structured enterprises. The governance levers that can be used to improve performance include people (selection, training, culture, incentives), process, tools and infrastructure, and organization; therefore, the assessment of systems engineering performance in an enterprise should cover these dimensions.

Being able to aggregate high quality data about the performance of teams with respect to SE activities is certainly of benefit when trying to guide team activities. Having access to comparable data, however, is often difficult, especially in organizations that are relatively autonomous, use different technologies and tools, build products in different domains, have different types of customers, etc. Even if there is limited ability to reliably collect and aggregate data across teams, having a policy that consciously decides how the enterprise will address data collection and analysis is valuable.

Performance Assessment Measures

Typical measures for assessing SE performance of an enterprise include the following:

- Effectiveness of SE process
- Ability to mobilize the right resources at the right time for a new project or new project phase
- Quality of SE process outputs
- Timeliness of SE process outputs
- SE added value to project
- System added value to end users
- SE added value to organization
- Organization's SE capability development
- Individuals' SE competence development
- Resource utilization, current and forecast
- Productivity of systems engineers
- Deployment and consistent usage of tools and methods

How Measures Fit in the Governance Process and Improvement Cycle

Since collecting data and analyzing it takes effort that is often significant, measurement is best done when its purpose is clear and is part of an overall strategy. The "goal, question, metric" paradigm (Basili 1992) should be applied, in which measurement data is collected to answer specific questions, the answer to which helps achieve a goal, such as decreasing the cost of creating a system architecture or increasing the value of a system to a particular stakeholder. Figure 1 shows one way in which appropriate measures inform enterprise level governance and drive an improvement cycle such as the Six Sigma DMAIC (Define, Measure, Analyze, Improve, Control) model.

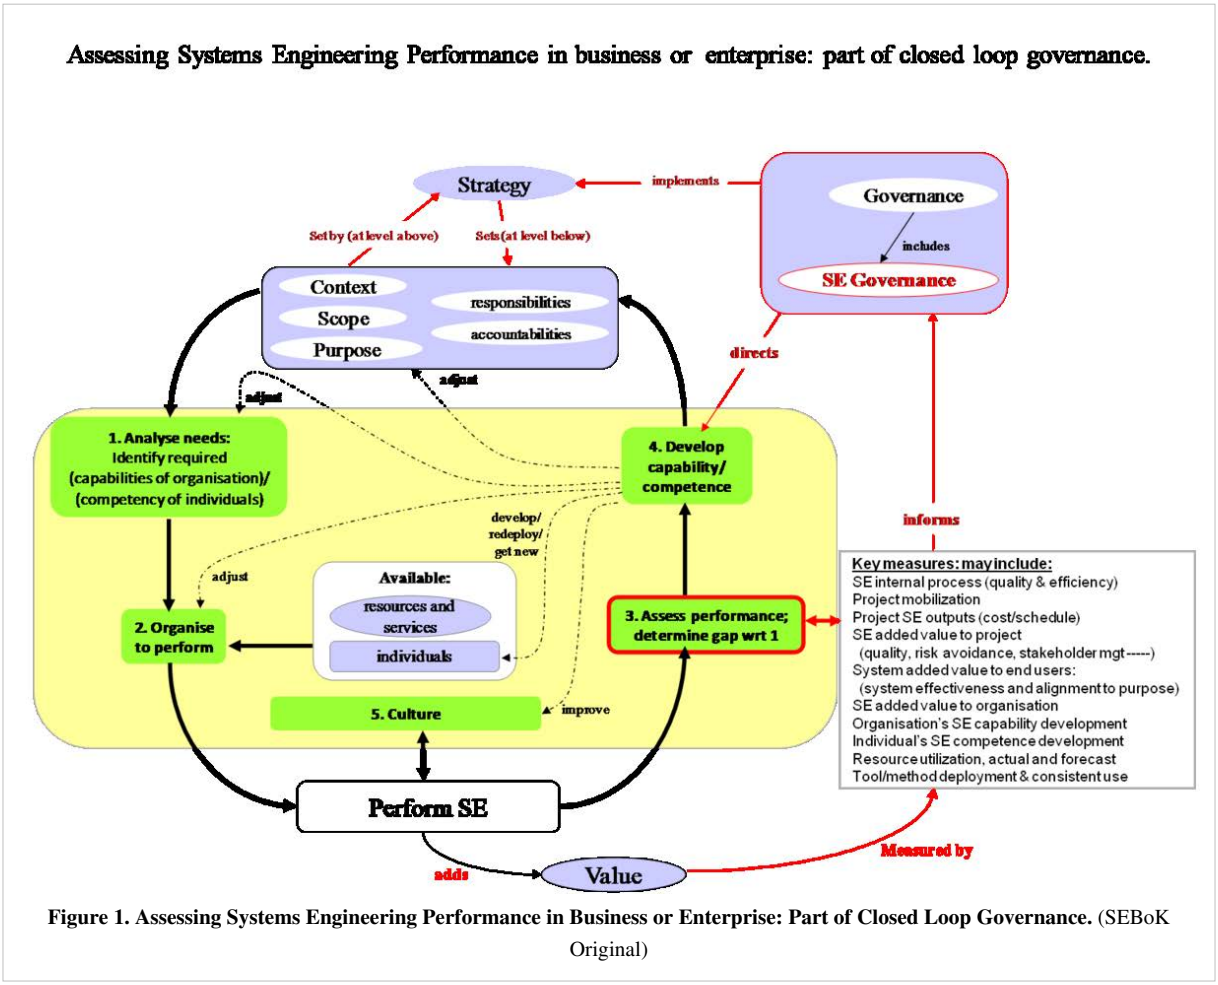

Figure 1. Assessing Systems Engineering Performance in Business or Enterprise: Part of Closed Loop Governance. (SEBoK Original)

Discussion of Performance Assessment Measures

Assessing SE Internal Process (Quality and Efficiency)

A process is a *"set of interrelated or interacting activities which transforms inputs into outputs."* The SEI CMMI Capability Maturity Model (SEI 2010) provides a structured way for businesses and enterprises to assess their SE processes. In the CMMI, a process area is a cluster of related practices in an area that, when implemented collectively, satisfies a set of goals considered important for making improvement in that area. There are CMMI models for acquisition, for development, and for services (SEI 2010, 11). CMMI defines how to assess individual process areas against Capability Levels on a scale from 0 to 3, and overall organizational maturity on a scale from 1 to 5.

Assessing Ability to Mobilize for a New Project or New Project Phase

Successful and timely project initiation and execution depends on having the right people available at the right time. If key resources are deployed elsewhere, they cannot be applied to new projects at the early stages when these resources make the most difference. Queuing theory shows that if a resource pool is running at or close to capacity, delays and queues are inevitable.

The ability to manage teams through their lifecycle is an organizational capability that has substantial leverage on project and organizational efficiency and effectiveness. This includes being able to

- mobilize teams rapidly;
- establish and tailor an appropriate set of processes, metrics and systems engineering plans;
- support them to maintain a high level of performance;
- capitalize acquired knowledge; and
- redeploy team members expeditiously as the team winds down.

Specialists and experts are used to a review process, critiquing solutions, creating novel solutions, and solving critical problems. Specialists and experts are usually a scarce resource. Few businesses have the luxury of having enough experts with all the necessary skills and behaviors on tap to allocate to all teams just when needed. If the skills are core to the business' competitive position or governance approach, then it makes sense to manage them through a governance process that ensures their skills are applied to greatest effect across the business.

Businesses typically find themselves balancing between having enough headroom to keep projects on schedule when things do not go as planned and utilizing resources efficiently.

Project SE Outputs (Cost, Schedule, Quality)

Many SE outputs in a project are produced early in the life cycle to enable downstream activities. Hidden defects in the early phase SE work products may not become fully apparent until the project hits problems in integration, verification and validation, or transition to operations. Intensive peer review and rigorous modeling are the normal ways of detecting and correcting defects in and lack of coherence between SE work products.

Leading indicators could be monitored at the organizational level to help direct support to projects or teams heading for trouble. For example, the INCOSE Leading Indicators report (Roedler et al. 2010) offers a set of indicators that is useful at the project level. Lean Sigma provides a tool for assessing benefit delivery throughout an enterprise value stream. Lean Enablers for Systems Engineering are now being developed (Oppenheim et al. 2010). An emerging good practice is to use lean value stream mapping to aid the optimization of project plans and process application.

In a mature organization, one good measure of SE quality is the number of defects that have to be corrected "out of phase"; i.e., at a later phase in the life cycle than the one in which the defect was introduced. This gives a good measure of process performance and the quality of SE outputs. Within a single project, the Work Product Approval, Review Action Closure, and Defect Error trends contain information that allows residual defect densities to be estimated (Roedler et al. 2010; Davies and Hunter 2001).

Because of the leverage of front-end SE on overall project performance, it is important to focus on quality and timeliness of SE deliverables (Woodcock 2009).

SE Added Value to Project

SE that is properly managed and performed should add value to the project in terms of quality, risk avoidance, improved coherence, better management of issues and dependencies, right-first-time integration and formal verification, stakeholder management, and effective scope management. Because quality and quantity of SE are not the only factors that influence these outcomes, and because the effect is a delayed one (good SE early in the project pays off in later phases) there has been a significant amount of research to establish evidence to underpin the asserted benefits of SE in projects.

A summary of the main results is provided in the Economic Value of Systems Engineering article.

System Added Value to End Users

System-added value to end users depends on system effectiveness and on alignment of the requirements and design to the end users' purpose and mission. System end users are often only involved indirectly in the procurement process.

Research on the value proposition of SE shows that good project outcomes do not necessarily correlate with good end user experience. Sometimes systems developers are discouraged from talking to end users because the acquirer is afraid of requirements creep. There is experience to the contrary – that end user involvement can result in more successful and simpler system solutions.

Two possible measures indicative of end user satisfaction are:

1. The use of user-validated mission scenarios (both nominal and "rainy day" situations) to validate requirements, drive trade-offs and organize testing and acceptance;
2. The use of technical performance measure (tpm) to track critical performance and non-functional system attributes directly relevant to operational utility. The INCOSE SE Leading Indicators Guide (Roedler et al. 2010, 10 and 68) defines "technical measurement trends" as *"Progress towards meeting the measure of effectiveness (moe) / measure of performance (mop) / Key Performance Parameters (KPPs) and technical performance measure (tpm)"*. A typical TPM progress plot is shown in Figure 2.

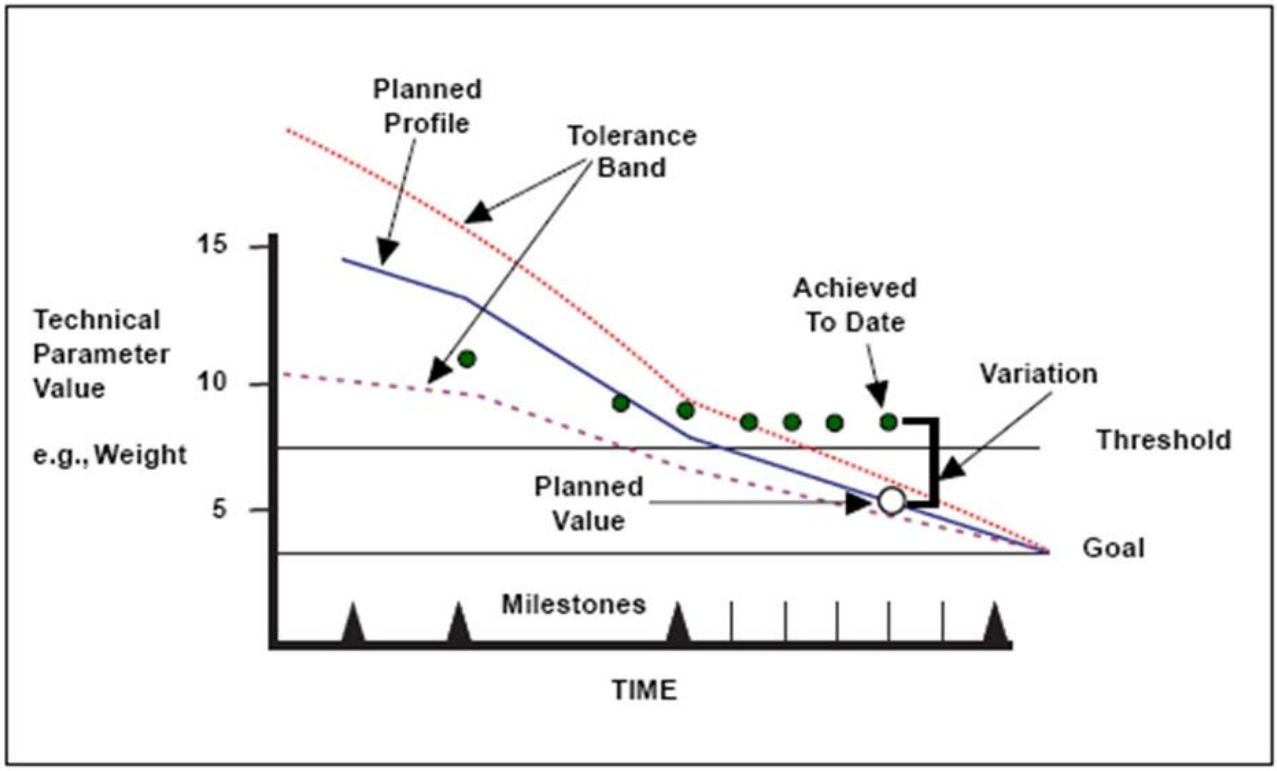

Figure 2. Technical Performance Measure (TPM) Tracking (Roedler et al. 2010). This material is reprinted with permission from the International Council on Systems Engineering (INCOSE). All other rights are reserved by the copyright owner.

SE Added Value to Organization

SE at the business/enterprise level aims to develop, deploy and enable effective SE to add value to the organization's business. The SE function in the business/enterprise should understand the part it has to play in the bigger picture and identify appropriate performance measures - derived from the business or enterprise goals, and coherent with those of other parts of the organization - so that it can optimize its contribution.

Organization's SE Capability Development

The CMMI (SEI 2010) provides a means of assessing the process capability and maturity of businesses and enterprises. The higher CMMI levels are concerned with systemic integration of capabilities across the business or enterprise.

CMMI measures one important dimension of capability development, but CMMI maturity level is not a direct measure of business effectiveness unless the SE measures are properly integrated with business performance measures. These may include bid success rate, market share, position in value chain, development cycle time and cost, level of innovation and re-use, and the effectiveness with which SE capabilities are applied to the specific problem and solution space of interest to the business.

Individuals' SE Competence Development

Assessment of Individuals' SE competence development is described in Assessing Individuals.

Resource Utilization, Current and Forecast

Roedler et al. (2010, 58) offer various metrics for staff ramp-up and use on a project. Across the business or enterprise, key indicators include the overall manpower trend across the projects, the stability of the forward load, levels of overtime, the resource headroom (if any), staff turnover, level of training, and the period of time for which key resources are committed.

Deployment and Consistent Usage of Tools and Methods

It is common practice to use a range of software tools in an effort to manage the complexity of system development and in-service management. These range from simple office suites to complex logical, virtual reality and physics-based modeling environments.

Deployment of SE tools requires careful consideration of purpose, business objectives, business effectiveness, training, aptitude, method, style, business effectiveness, infrastructure, support, integration of the tool with the existing or revised SE process, and approaches to ensure consistency, longevity and appropriate configuration management of information. Systems may be in service for upwards of 50 years, but storage media and file formats that are 10-15 years old are unreadable on most modern computers. It is desirable for many users to be able to work with a single common model; it can be that two engineers sitting next to each other using the same tool use sufficiently different modeling styles that they cannot work on or re-use each others' models.

License usage over time and across sites and projects is a key indicator of extent and efficiency of tool deployment. More difficult to assess is the consistency of usage. Roedler et al. (2010, 73) recommend metrics on "facilities and equipment availability".

Practical Considerations

Assessment of SE performance at the business/enterprise level is complex and needs to consider soft issues as well as hard issues. Stakeholder concerns and satisfaction criteria may not be obvious or explicit. Clear and explicit reciprocal expectations and alignment of purpose, values, goals and incentives help to achieve synergy across the organization and avoid misunderstanding.

"What gets measured gets done." Because metrics drive behavior, it is important to ensure that metrics used to manage the organization reflect its purpose and values, and that they do not drive perverse behaviors (Roedler et al. 2010).

Process and measurement cost money and time, so it is important to get the right amount of process definition and the right balance of investment between process, measurement, people and skills. Any process flexible enough to allow innovation will also be flexible enough to allow mistakes. If process is seen as excessively restrictive or prescriptive, it may inhibit innovation and demotivate the innovators in an effort to prevent mistakes, leading to excessive risk avoidance.

It is possible for a process improvement effort to become an end in itself rather than a means to improve business performance (Sheard 2003). To guard against this, it is advisable to remain clearly focused on purpose (Blockley and Godfrey 2000) and on added value (Oppenheim et al. 2010) as well as to ensure clear and sustained top management commitment to driving the process improvement approach to achieve the required business benefits. Good process improvement is as much about establishing a performance culture as about process.

> *The Systems Engineering process is an essential complement to, and is not a substitute for, individual skill, creativity, intuition, judgment etc. Innovative people need to understand the process and how to make it work for them, and neither ignore it nor be slaves to it. Systems Engineering measurement shows where invention and creativity need to be applied. SE process creates a framework to leverage creativity and innovation to deliver results that surpass the capability of the creative individuals – results that are the emergent properties of process, organisation, and leadership.* (Sillitto 2011)

Developing Systems Engineering Capabilities within Businesses and Enterprises

- Lead Authors:
- Richard Beasley, Hillary Sillitto, and Alice Squires
- Contributing Authors:
- Heidi Davidz and Art Pyster

-

The pursuit of continuous improvement is a constant for many organizations. The description of Toyota (Morgan and Liker 2006), the Lean principle of “pursue perfection” (Oppenheim et al. 2010), and the principle of “don’t let up” (Kotter 1995), all drive a need for continuous improvement.

The ability to manage teams through their lifecycle – mobilize teams rapidly, establish and tailor an appropriate set of processes, metrics and systems engineering plans, support them to maintain a high level of performance, capitalize acquired knowledge and redeploy team members expeditiously as the team winds down – is a key organizational competence that has substantial leverage on project and organizational efficiency and effectiveness.

The enterprise provides teams with the necessary resources, background information, facilities, cash, support services, tooling, etc. It also provides a physical, cultural and governance environment in which the teams can be effective. The key functions of the enterprise include generating and maintaining relevant resources, allocating them to teams, providing support and governance functions, maintaining expertise and knowledge (on process, application domain and solution technologies), securing the work that teams perform, organizing finance, and maintaining the viability of the enterprise.

For improvements to persist, they must reside in the enterprise rather than just the individuals, so the improvements can endure as personnel leave. This is reflected in the Capability Maturity Model Integrated (CMMI) (SEI 2010) progression from a "hero culture" to a "quantitatively managed and optimizing process".

This topic outlines the issues to be considered in capability development and organizational learning.

Overview

Figure 1 shows an "analyze – organize – perform – assess – develop" cycle, which is essentially a reformulation of the Deming (1994) PDCA (Plan Do Check Act) cycle. The analysis step should cover both current and future needs, as far as these can be determined or predicted. Goals and performance assessment, as discussed in Assessing Systems Engineering Performance of Business and Enterprises, can be based on a number of evaluation frameworks, such as direct measures of business performance and effectiveness and the CMMI capability maturity models. There is evidence that many organizations find a positive correlation between business performance and CMMI levels (SEI 2010). This is discussed further in the Economic Value of Systems Engineering.

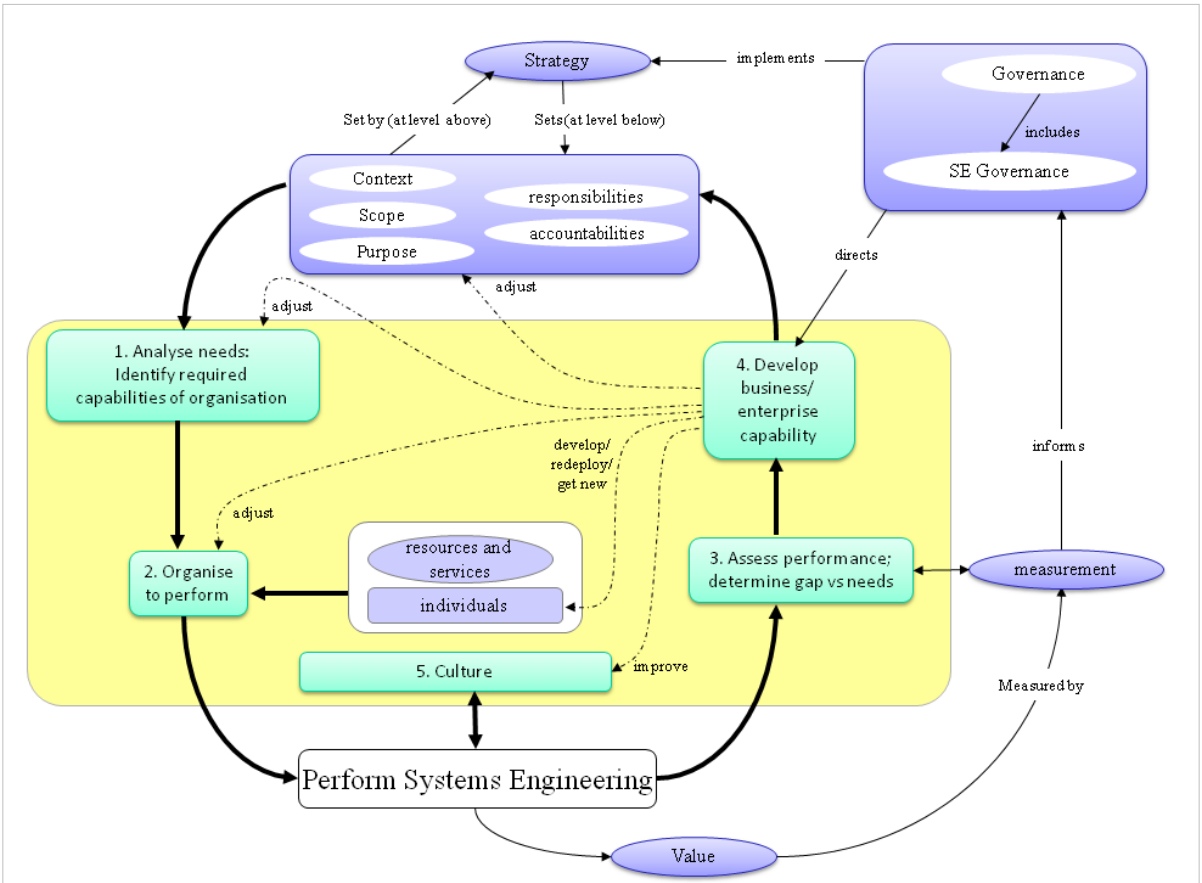

Figure 1. Concept Map for Businesses and Enterprises Topics. (SEBoK Original)

Change Levers

SE managers have a number of possible change levers they can use to develop SE capabilities. The amount of time delay between moving a lever and seeing the effect varies with the type of level, size of the enterprise, culture of the enterprise, and other factors.

Adjust Context, Scope, Purpose, Responsibility, Accountability Business Enterprise

If the other change levers cannot achieve the desired effect, the business or enterprise may have to renegotiate its contribution to the higher-level strategy and mission.

Review and Adjust Required Capabilities

In the initial analysis the needed capability may have been over- or under-estimated. The need should be re-evaluated after each rotation of the cycle to make sure the planning assumptions are still valid.

Adjust Organization within Business Enterprise

Adjusting organization and responsibilities so that *"the right people are doing the right things"*, and ensuring that the organization is making full use of their knowledge and skills, is often the easiest change to make (and the one that may have the quickest effect).

A potential risk is that too much organizational churn disrupts relationships and can destabilize the organization and damage performance. Process improvement can be set back by an ill-considered re-organization and can jeopardize any certifications the organization has earned which demonstrate its process capability or performance.

Develop/Train/Redeploy/Get New Resources, Services and Individuals

Resources, services and individuals may include any of the components of organizational SE capability listed in Organizing Business and Enterprises to Perform Systems Engineering.

Levers include subcontracting elements of the work, improving information flows, upgrading facilities, and launching short-term training and/or long-term staff development programs. Many organizations consider how they approach these improvements to be proprietary, but organizations such as NASA offer insight on their APPEL website (NASA 2012).

Development of individuals is discussed in Enabling Individuals.

Improve Culture

Culture change is very important and powerful but needs to be handled as a long-term game and given long term commitment.

Adjust and Improve Alignment of Measures and Metrics

Measurement drives behavior. Improving alignment of goals and incentives of different parts of the business/enterprise so that everyone works to a common purpose can be a very effective and powerful way of improving business/enterprise performance. This alignment does require some top-down guidance, perhaps a top-down holistic approach, considering the business/enterprise as a system with a clear understanding of how the elements of enterprise capability interact to produce synergistic value (See Assessing Systems Engineering Performance of Business and Enterprises). It is commonly reported that as an organization improves its processes with respect to the CMMI, its approach to metrics and measurement has to evolve.

Change Methods

Doing Everyday Things Better

There is a wealth of sources and techniques, including Kaizen, Deming PDCA (Deming 1994), Lean (Womack and Jones 2003, Oppenheim et al. 2010), Six-Sigma (Harry 1997), and CMMI.

Value stream mapping is a powerful Lean technique to find ways to improve flow and handovers at interfaces.

Managing Technology Readiness

In high-technology industries many problems are caused by attempting to transition new technologies into products and systems before the technology is mature; to make insufficient allowance for the effort required to make the step from technology demonstration to reproducible and dependable performance in a product; or to overestimate the re-usability of an existing product. NASA's TRL (Technology Readiness Level) construct, first proposed by John Mankins in 1995 (Mankins 1995), is widely and successfully used to understand and mitigate technology transition risk. Several organizations beyond NASA, such as the U.S. Department of Defense, even have automation to aid engineers in evaluating technology readiness.

Variations on TRL have emerged, such as System Readiness Levels (SRL) (Sauser et al. 2006), which recognize that the ability to successfully deliver systems depends on much more than the maturity of the technology base used to create those systems; e.g., there could be surprising risks associated with using two technologies that are relatively mature in isolation, but have never been integrated together before.

Planned Change: Standing Up or Formalizing SE in an Organization

Planned change may include:

- introducing SE to a business (Farncombe and Woodcock 2009);
- improvement/transformation;
- formalizing the way a business or project does SE;
- dealing with a merger/demerger/major re-organization;
- developing a new generation or disruptive product, system, service or product line (Christensen 1997);
- entering a new market; and
- managing project lifecycle transitions: start-up, changing to the next phase of development, transition to manufacture/operation/support, wind down and decommissioning.

CMMI is widely used to provide a framework for planned change in a systems engineering context. Planned change needs to take a holistic approach considering people (knowledge, skills, culture, ability and motivation), process, measurement and tools as a coherent whole. It is now widely believed that tools and process are not a substitute for skills and experience. Instead, they merely provide a framework in which skilled and motivated people can be more effective. Therefore, change should start with people rather than with tools.

Before a change is started, it is advisable to baseline the current business performance and SE capability and establish metrics that will show early on whether the change is achieving the desired effect.

Responding to Unforeseen Disruption

Unforeseen disruptions may be internally or externally imposed. Externally imposed disruptions may be caused by:

- the customer – win/lose contract, mandated teaming or redirection;
- competitors – current offering becomes more/less competitive, a disruptive innovation may be launched in market; or
- governance and regulatory changes – new processes, certification, safety or environmental standards.

Internal or self-induced disruptions may include:

- a capability drop-out due to loss of people, facilities, financing;
- product or service failure in operation or disposal; or
- strategy change (e.g. new CEO, response to market dynamics, or a priority override).

Embedding Change

In an SE context, sustained effort is required to maintain improvements such as higher CMMI levels, Lean and Safety cultures, etc., once they are achieved. There are several useful change models, including Kotter's 8 phases of change (Kotter 1995):

1. Establish a sense of urgency;
2. Create a coalition;
3. Develop a clear vision;
4. Share the vision;
5. Empower people to clear obstacles;
6. Secure short-term wins;
7. Consolidate and keep moving; and
8. Anchor the change.

The first six steps are the easy ones. The Chaos Model (Zuijderhoudt 1990; 2002) draws on complexity theory to show that regression is likely if the short-term wins are not consolidated, institutionalized and anchored. This explains the oft-seen phenomenon of organizations indulging in numerous change initiatives, none of which stick because attention moves on to the next before the previous one is anchored.

Change Management Literature

SE leaders (directors, functional managers, team leaders and specialists) have responsibilities, and control levers to implement them, that vary depending on their organization's business model and structure. A great deal of their time and energy is spent managing change in pursuit of short-, medium- and long-term organizational goals: "doing everyday things better"; making change happen; embedding change and delivering the benefit; and coping with the effects of disruptions. Mergers, acquisitions and project start-ups, phase changes, transitions from "discovery" to "delivery" phase, transition to operation, sudden change in level of funding, can all impose abrupt changes on organizations that can destabilize teams, processes, culture and performance. Table 1 below provides both the general management literature and specific systems engineering knowledge.

Table 1. Change Management – Business and SE References. (SEBoK Original)

Area	Business references	SE references
Doing Every-day Things Better	• Kaizen; Lean (Womack and Jones 2003); 6-Sigma (Harry 1997) • Four Competencies of Learning Organisation – Absorb, Diffuse, Generate, Exploit (Sprenger and Ten Have 1996) • The Seven Habits of Very Effective People (Covey 1989)	• CMMI • Visualizing Project Management (Forsberg and Mooz 2005) • INCOSE IEWG "Conops for a Systems Engineering Educational Community" (Ring and Wymore 2004) • INCOSE Lean Enablers for SE (Oppenhein et al. 2010)

Barriers to Successful Embedding of Systems Engineering into Organizations

- Lead Author:
- Bernardo Delicado
- Contributing Author:
- Tom Strandberg, Ivan Mactaggart

-

The landscape of industry is evolving rapidly, presenting formidable challenges in the development of complex technical products. Systems Engineering (SE) emerges as a promising solution to tackle these challenges. In recent years, the awareness and significance of SE have surged within industry sectors such as automotive, railway, aerospace, and defense. However, the actual embedding of SE into organizational frameworks poses a significant challenge for many companies operating within these sectors and others.

Introducing SE entails not only dealing with technical complexity but also significant human aspects of change which are critical to ensuring stakeholder engagement, smooth adoption, and the long-term success of the initiative. Various impacts of change, including restructuring, reengineering, and cultural shifts, must be addressed through effective change management techniques to ensure successful SE integration.

This article aims to delve into the complexities surrounding the embedding of SE into organizations. By examining the struggles encountered by companies, we seek to uncover the underlying reasons behind these challenges. Expectations towards SE are scrutinized, and an analysis of the barriers hindering its adoption is presented, drawing insights from the experiences of two non-participating customers. Additionally, we outline ten essential requirements crucial for the successful embedding of SE, comparing them with available introduction methodologies.

Industrial Challenges

Systems Engineering (SE) offers an approach to handle complexity. Despite these potential benefits in product development, the adoption of SE varies significantly by industry, being more prevalent in the aerospace, defense, and automotive sectors than in other areas. Furthermore, SE is more commonly used in large corporations than small and medium-sized enterprises (SMEs). SMEs face challenges in accessing and building SE expertise due to limited resources and varying SE needs depending on the specific projects and applications of each SME.

The complexity of products and their development is rising due to trends like digitalization, globalization, and sustainability. Companies are encountering new hurdles as they transition from traditional mechatronic products to autonomous, interactive, and dynamically networked systems. This shift, along with the increasing interdisciplinarity of their systems and enhanced networking with other systems, contributes to the escalating complexity in product development.

While SE is a holistic approach to address such challenges, its adoption remains relatively nascent within organizations. Historically, development approaches have been discipline-oriented, lacking the systemic perspective required for tomorrow's products. Consequently, the introduction of SE presents a formidable challenge, given the established discipline-centric mindset prevalent in all industries and application domains.

A Holistic Approach

The Capability Model approach recognizes that building a lasting organizational capability requires more than process and tools. As illustrated in the Figure 1 below, the elements that build up a SE organizational capability include Governance, Organisation, Process, Process support, Information and Technology & Infrastructure.

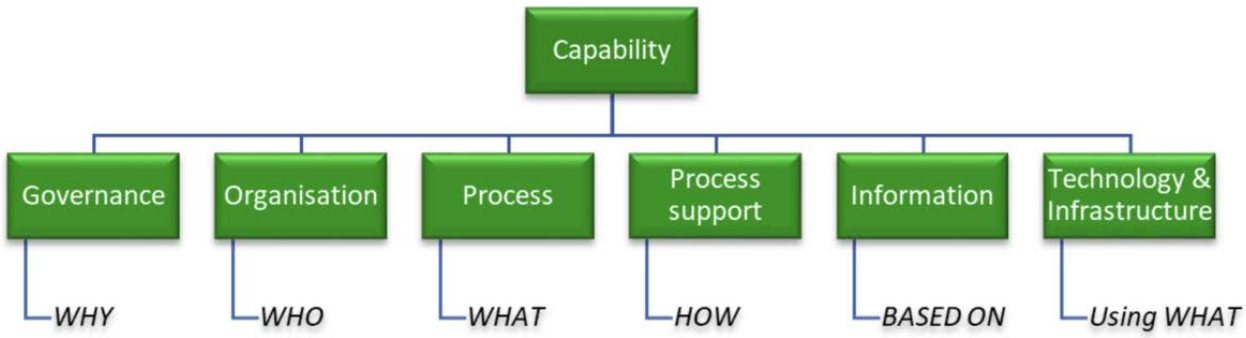

Figure 1. The Capability Model (Strandberg, et al, 2024). Copyright © (2024). All Rights Reserved. Reprinted by Permission. All other rights are reserved by the copyright owner.

Furthermore, the level of organizational capability needed should be based on the context in which it operates. The contextual factors can be divided into Business, Organizational and Product related aspects as shown in Figure 2.

A capability the ability of an entity (department, organization, person, system) to achieve its objectives, specifically in relation to its overall mission. Only when this is used in business operations will the desired effects, such as improved quality, reduced lead-times and enhanced cost-effectiveness, be realized.

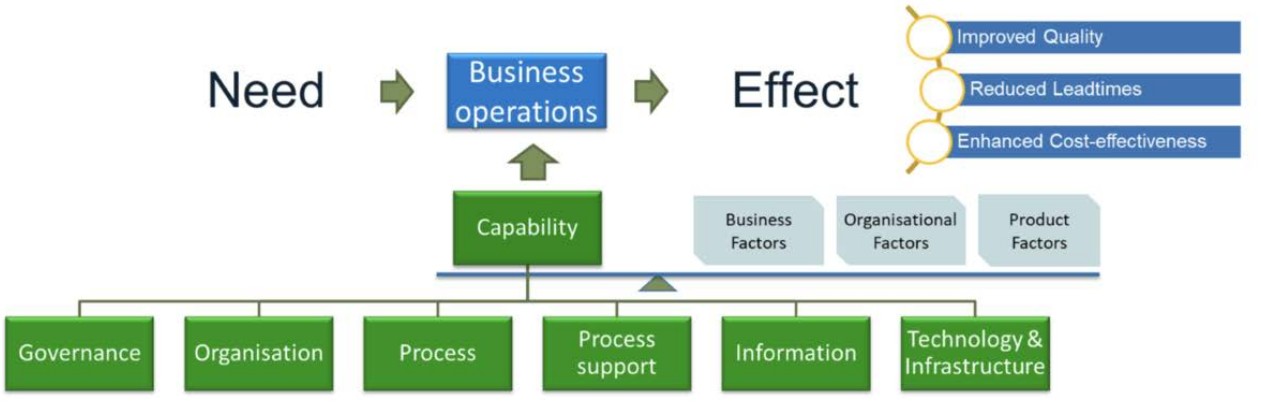

Figure 2. The Capability Model with Contextual Factors (Strandberg, et al, 2024). Copyright © (2024). All Rights Reserved. Reprinted by Permission. All other rights are reserved by the copyright owner.

Implementation of recognized SE standards

Any embedding of SE in an organization should start with a formulation of the Why. As illustrated in the Capability Model, this falls under the Governance element. One common approach involves the tailoring and implementation of recognized standards, such as those outlined by the International Organization for Standardization (ISO). This strategic framework outlines the essential steps involved in implementing SE standards as shown in Figure 3, offering organizations a roadmap for success.

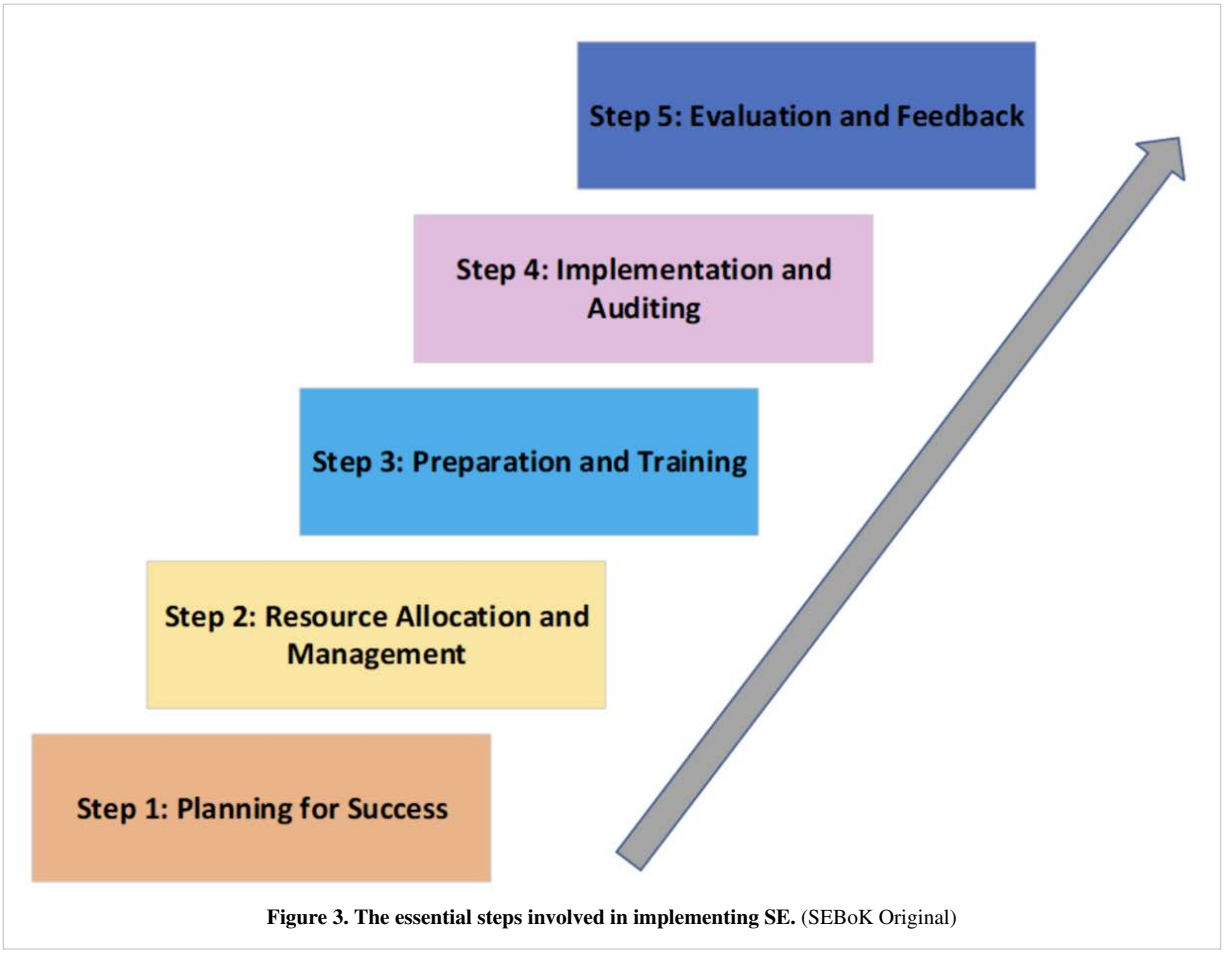

Figure 3. The essential steps involved in implementing SE. (SEBoK Original)

Step 1: Planning for Success

The first stage in implementing an SE standard is thorough planning to ensure smooth integration. This phase includes:

- To understand the current maturity of the organization, baselining what is done or not done and then considering how you might effectively implement.
- Identifying the appropriate industry standards that the organization will seek to comply with and the level of capability desired. Many of these standards describe a list of activities to be performed by an organization and its projects to demonstrate the capability.
- Identifying gaps and areas of non-compliance by mapping current activities against the established activities within the standards for the capability to be achieved.
- Evaluating the necessary process and organizational changes for successful embedding of SE.
- Securing commitment and support from organizational leadership for the resources required (and maintaining this commitment throughout the implementation process).

Step 2: Resource Allocation and Management

Proper resource allocation is critical for successful SE standard implementation. This step involves:

- Appointing a dedicated SE standard implementation manager to oversee the process and ensure timelines and objectives are met.
- Developing a detailed resource plan and schedule, outlining the allocation of personnel, finances, and technological infrastructure needed for SE implementation.
- Gaining approval from organizational leadership for funding and scheduling to ensure smooth execution of the implementation plan.

Step 3: Preparation and Training

Preparing the organization for embedding of SE requires effective communication and comprehensive training initiatives. This phase includes:

- Creating a communication and training plan to disseminate information about SE standards and build organizational readiness.
- Updating organizational policies, procedures, and work instructions to incorporate new SE tasks and methodologies.
- Conducting training sessions at all levels of the organization to provide personnel with the necessary knowledge and skills for SE implementation.

Step 4: Implementation and Auditing

The implementation phase involves systematically executing SE standards, with ongoing monitoring and evaluation. Key activities include:

- Implementing one action or item at a time to ensure gradual and sustainable integration.
- Performing regular audits to assess adherence to SE standards and identify areas for improvement.

Step 5: Evaluation and Feedback

Evaluating the effectiveness of SE implementation is essential to understand its impact and identify opportunities for refinement. This phase involves:

- Managing schedules and resources to facilitate thorough reviews of newly implemented standard tasks.
- Informing the organization upon project completion, highlighting achievements, and outlining future milestones.

Requirements for SE Introduction

The successful embedding of SE into organizational workflows requires careful consideration of various factors and adherence to specific requirements. The integration of SE standards serves as a cornerstone for organizations aiming to optimize their engineering processes and deliver high-quality products and services to market.

By adhering to established standards and best practices, companies can effectively navigate the complexities of modern engineering challenges while ensuring consistency, reliability, and efficiency across all facets of their operations. However, the journey towards SE integration is not without its challenges, as organizations must navigate a myriad of considerations to ensure successful implementation.

As we explore the nine crucial requirements for embedding of SE outlined below, it becomes evident that a strategic and holistic approach is essential for realizing the full potential of SE within an organizational context:

1. Create the vision and roadmap for embedding of SE
2. Providing a flexible implementation strategy tailored to organizational needs.
3. Providing comprehensive support for SE rollout within organizations.

4. Incorporating change management strategies into SE implementation efforts.
5. Tailoring SE considering the characteristics of companies or organizations (first level of tailoring).
6. Implementing SE through both top-down and bottom-up approaches.
7. Introducing tailoring to adapt SE approaches to specific project requirements (second level of tailoring).
8. Integrating SE with Model-Based Systems Engineering (MBSE).
9. Ensuring the selection of a tool or tools that meet your needs in terms of processes and methods.

Barriers for Organizations

While the adoption of standardized best practices as provided by ISO standards lays a solid foundation for embedding of SE within organizations, the journey is often fraught with challenges and barriers that must be navigated with precision and foresight.

From rigid organizational structures to cultural resistance and the nebulous nature of quantifiable benefits, each barrier presents unique challenges that must be addressed to ensure the successful integration of SE within organizational workflows.

By understanding and addressing these barriers head-on, organizations can navigate the complexities of SE integration with confidence and precision, unlocking the full potential of standardized methodologies to drive innovation, efficiency, and competitiveness in today's dynamic business landscape.

Rigid Organizational Structures

The inherent rigidity of organizational structures poses a significant obstacle to SE integration, hindering the necessary adaptations and restructuring required to accommodate new methodologies and approaches.

Slow Decision-Making Processes

Delays in decision-making processes impede the timely implementation of SE methodologies, prolonging the transition and inhibiting organizational agility and responsiveness.

Resistance to Change

Cultural resistance and entrenched silo thinking contradict the holistic principles of SE, necessitating a fundamental cultural shift and fostering a culture of collaboration and cooperation across organizational boundaries.

Specialization Challenges

While specialization is essential for complex product development, it can complicate the internal allocation of SE roles, which often require a more generalized skill set and interdisciplinary collaboration.

Non-Quantifiable Benefits

The intangible nature of SE benefits, coupled with a lack of key performance indicators (KPIs) to substantiate its efficacy, poses significant challenges to its adoption and integration within organizations.

Insufficient Provision of Resources

Inadequate provision of introduction methods, expertise, and resources further complicates the adoption and successful implementation of SE methodologies, undermining the effectiveness of integration efforts.

Neglecting Non-Technical Aspects

Overlooking non-technical aspects such as stakeholder needs and inadequate change management strategies can undermine the success of SE integration efforts, emphasizing the importance of a holistic and comprehensive approach.

Lack of skilled professionals

One of the major barriers to integrating SE in an organization is the shortage of well-trained and professionally competent personnel in this field. The absence of qualified experts hinders the effective implementation of SE methods and tools, which can slow down projects and impact the quality of outcomes.

Conclusion

Embedding of SE into organizations requires a holistic approach, covering both establishing the appropriate level of capability and the careful implementation thereof.

While the adoption of established SE standards provides a solid foundation for integration, organizations must also recognize the need to tailor these approaches to suit their specific project requirements and organizational objectives. By combining standardized methodologies with bespoke strategies tailored to their unique needs, companies can leverage the full potential of SE to drive value creation and achieve sustainable competitive advantage.

In conclusion, the successful embedding of Systems Engineering into organizations requires a multifaceted approach addressing technical, cultural, and organizational challenges. By understanding and addressing these barriers, companies can unlock the full potential of SE to drive innovation and achieve sustainable growth.

Culture

- Lead Authors:
- Scott Jackson, Hillary Sillitto, and John Snoderly
- Contributing Authors:
- Richard Turner, Art Pyster, and Richard Beasley

-

Establishing and managing cultures, values, and behaviors is a critical aspect of systems engineering, especially in the context of deploying SE within an organization (Fasser and Brettner 2002). The Columbia Accident Investigation Report (NASA 2003, 101), defines *culture* as *"the basic values, norms, beliefs, and practices that characterize the functioning of a particular institution."*

Stable safety and process cultures are key to effective SE, and can be damaged by an overly-rapid pace of change, a high degree of churn (see the Nimrod Crash Report, Haddon-Cave 2009), or by change that engineers perceive as arbitrarily imposed by management (see Challenger, discussed below). On the other hand, a highly competitive, adversarial or "blame" culture can impede the free flow of information and disrupt synergies in the workplace.

In the multi-national, multi-business, multi-discipline collaborative projects becoming increasingly prevalent in SE, these factors take on greater importance.

Effective handling of cultural issues is a major factor in the success or failure of SE endeavors.

Systems Thinking and the Culture of the Learning Organization

Improving SE efficiency and effectiveness can be the goal of culture change. This kind of culture change encourages people to learn to think and act in terms of systems, organizations and their enterprises; and, to take a systems approach as described in Overview of Systems Approaches in Part 2, and by Lawson (2010). See the knowledge area Systems Thinking.

Attaining a *learning organization* culture can be another goal of cultural change. And once the learning organization exists, cultural change in general becomes easier to accomplish.

A learning organization aims to absorb, diffuse, generate, and exploit knowledge (Sprenger and Have 1996). Organizations need to manage formal information and facilitate the growth and exploitation of tacit knowledge. They should learn from experience and create a form of *corporate memory* – including process, problem domain and solution space knowledge, and information about existing products and services. Fassner and Brettner (2002, 122-124) suggest that *shared mental models* are a key aspect of corporate knowledge and culture.

A learning organization culture is enabled by disciplines such as:

- **personal mastery,** where a person continually clarifies and deepens personal vision, focuses energy upon it and develops patience in seeking it so as to view reality in an increasingly objective way;
- **mental models,** where people appreciate that mental models do indeed occupy their minds and shape their actions;
- **shared vision,** where operating values and sense of purpose are shared to establish a basic level of mutuality; and
- **team learning,** where people's thoughts align, creating a feeling that the team as a whole achieves something greater than the sum of what is achieved by its individual members.

Systems thinking supports these four disciplines, and in so doing becomes the **fifth discipline** and plays a critical role in promoting the learning organization (Senge et al. 1994).

Cultural Shortfalls and How to Change Them

Cultural shortfalls that are injurious to a system are described as negative paradigms by Jackson (2010) and others. For example, a cultural reluctance to identify true risks is the hallmark of the **Risk Denial** paradigm as seen in the Challenger and Columbia cases. When individuals believe a system is safe that is in fact unsafe, that is the **Titanic Effect** paradigm, which is of course named for the ocean liner catastrophe of 1912.

Approaches to Change

Jackson and Erlick (Jackson 2010, 91-119) have found that there is a lack of evidence that a culture can be changed from a success point of view. However, they do suggest the Community of Practice (Jackson 2010, 110-112), an approach founded on the principles of organizational psychology, and discuss the pros and cons of other approaches to culture change, including training, coaching, Socratic teaching, use of teams, independent reviews, standard processes, rewards and incentives, use of cost and schedule margins, reliance on a charismatic executive, and management selection. Shields (2006) provides a similarly comprehensive review.

The Columbia Accident (NASA 2003) and the Triangle fire (NYFIC 1912) official reports, among many others, call for cultural issues to be addressed through improved leadership, usually augmented by the more objective approach of auditing. One form of auditing is the Independent Technical Authority, which:

- is separate from the program organization;
- addresses only technical issues, not managerial ones; and
- has the right to take action to avoid failure, including by vetoing launch decisions.

An Independent Technical Authority cannot report to the program manager of the program in question, and it may be formulated within an entirely separate business or enterprise which can view that program objectively. The point of these stipulations is to ensure that the Independent Technical Authority is indeed independent.

Management and leadership experts have identified ways to lead cultural change in organizations, apart from specifically safety-related cultural change. For example, Gordon (1961) in his work on the use of analogical reasoning called synectics is one of several who emphasize creative thinking. Kotter (1995) advocates a series of steps to transform an organization.

How Culture Manifests in Individuals and Groups

As a community's physical, social, and religious environment changes over the generations, cultural beliefs, values, and customs evolve in response, albeit at a slower pace.

Helmreich and Merritt describe the effects of cultural factors in the context of aviation safety and suggest implications for safety cultures in other domains such as medicine. See (Helmreich and Merritt, 2000) and other writings by the same authors.

We can describe the cultural orientation of an individual in terms of:

- national and/or ethnic culture;
- professional culture; and
- organizational culture.

Some particulars of these aspects of culture are sketched below.

National and/or Ethnic Culture

A product of factors such as heritage, history, religion, language, climate, population density, availability of resources, politics, and national culture is acquired in one's formative years and is difficult to change. National culture affects attitudes, behavior, and interactions with others.

National culture may help determine how a person handles or reacts to:

- rules and regulations;
- uncertainty; and
- display of emotion, including one's own.

National culture may also play a role in whether a person

- communicates in a direct and specific style, or the opposite;
- provides leadership in a hierarchical manner, or a consultative one; and
- accepts decisions handed down in superior–inferior relationships, or questions them.

Professional Culture

Professional culture acts as an overlay to ethnic or national culture, and usually manifests in a sense of community and in bonding based on a common identity (Helmreich and Merritt 2000). Well-known examples of professional cultures include those of medical doctors, airline pilots, teachers, and the military.

Elements of professional culture may include:

- a shared professional jargon
- binding norms for behavior
- common ethical values
- self-regulation
- barriers to entry such as selectivity, competition and training
- institutional and/or individual resistance to change
- prestige and status, sometimes expressed in badges or uniforms
- stereotyped notions about members of the profession, in general and/or based on gender

Particularly important elements of professional culture (for example, those that affect safety or survivability) need to be inculcated by extensive training and reinforced at appropriate intervals.

Organizational Culture

An organization's culture builds up cumulatively, determined by factors like its leadership, products and services, relationships with competitors, and role in society.

Compared with one another, organizational cultures are not standardized because what works in one organization seldom works in another. Even so, strength in the following elements normally engenders a strong organizational culture:

- corporate identity;
- leadership;
- morale and trust;
- teamwork and cooperation;
- job security;
- professional development and training;
- empowerment of individuals; and
- confidence, for example in quality and safety practices, or in management communication and feedback.

When the culture of the people in an organization is considered as a whole, organizational culture acts as a common layer shared by all. Despite this, differing national cultures can produce differences in leadership styles, manager-subordinate relationships, and so on, especially in organizations with a high degree of multinational integration.

Because organizations have formal hierarchies of responsibility and authority, organizational culture is more amenable to carefully planned change than are either professional or national cultures. If changes are made in a manner that is sympathetic to local culture (as opposed to that of a distant group head office, for example), they can bring significant performance benefits. This is because organizational culture channels the effects of national and professional cultures into standard working practices.

There are many definitions of culture in the literature. The Columbia Accident Investigation Board (NASA 2003) provides a useful definition for understanding culture and engineering.

Culture and Safety

Reason (1997, 191-220) describes a culture which focuses on safety as having four components:

1. A reporting culture which encourages individuals to report errors and near misses, including their own.
2. A just culture which provides *an atmosphere of trust in which people are encouraged, even rewarded, for providing essential safety-related information.*
3. A flexible culture which abandons the traditional hierarchical reporting structure in favor of more direct team-to-team communications.
4. A learning culture which is willing to draw the right conclusions from safety-related information and to implement reforms when necessary.

Weick and Sutcliffe (2001, 3) introduce the term high reliability organizations (hros). HROs have *fewer than their fair share of accidents* despite operating *under trying conditions* in domains subject to catastrophic events. Examples include *power grid dispatching centers, air traffic control systems, nuclear aircraft carriers, nuclear power generation plants, hospital emergency departments, and hostage negotiation teams.* There are five hallmarks of HROs (Weick and Sutcliffe 2001, 10):

1. **Preoccupation with Failure—**HROs eschew complacency, learn from near misses, and do not ignore errors, large or small.
2. **Reluctance to Simplify Interpretations—**HROs simplify less and see more. They "encourage skepticism towards received wisdom."
3. **Sensitivity to Operations—**HROs strive to detect "latent failures," defined by James Reason (1997) as systemic deficiencies that amount to accidents waiting to happen. They have well-developed situational awareness and make continuous adjustments to keep errors from accumulating and enlarging.
4. **Commitment to Resilience—**HROs keep errors small and improvise "workarounds that keep the system functioning." They have a deep understanding of technology and constantly consider worst case scenarios in order to make corrections.
5. **Deference to Expertise—**HROs "push decision making down." Decisions are made "on the front line." They avoid rigid hierarchies and go directly to the person with the expertise.

The US Nuclear Regulatory Agency (2011) focuses mainly on leadership and individual authority in its policy statement on safety culture.

Historical Catastrophes and Safety Culture

The cases described in the table below are some of the many in which official reports or authoritative experts cited culture as a factor in the catastrophic failure of the systems involved.

Example	Cultural Discussion
Apollo	According to Feynman (1988), Apollo was a successful program because of its culture of *"common interest."* The *"loss of common interest"* over the next 20 years then caused *"the deterioration in cooperation, which . . . produced a calamity."*
Challenger	Vaughn (1997) states that rather than taking risks seriously, NASA simply ignored them by calling them normal—what she terms *"normalization of deviance,"* whose result was that *"flying with acceptable risks was normative in NASA culture."*
Columbia	The Columbia Accident Investigation Report (NASA 2003, 102) echoed Feynman's view and declared that NASA had a *"broken safety culture."* The board concluded that NASA had become a culture in which bureaucratic procedures took precedence over technical excellence.
Texas City - 2005	On August 3, 2005, a process accident occurred at the BP refinery in a Texas City refinery in the USA resulting in 19 deaths and more than 170 injuries. The Independent Safety Review Panel (2007) found that a corporate safety culture existed that *"has not provided effective process safety leadership and has not adequately established process safety as a core value across all its five U.S. refineries."* The report recommended *"an independent auditing function."*
The Triangle Fire	On August 11, 1911, a fire at the Triangle shirtwaist factory in New York City killed 145 people, mostly women (NYFIC 1912). The New York Factory Investigating Commission castigated the property owners for their lack of understanding of the *"human factors"* in the case and called for the establishment of standards to address this deficiency.
Nimrod	On September 2, 2006, a Nimrod British military aircraft caught fire and crashed, killing its entire crew of 14. The Haddon-Cave report (Haddon-Cave 2009) found that Royal Air Force culture had come to value staying within budget over airworthiness. Referencing the conclusions of the Columbia Accident Investigation Report, the Haddon-Cave report recommends creation of a system of detailed audits.

Relationship to Ethics

A business's culture has the potential to reinforce or undermine ethical behavior. For example, a culture that encourages open and transparent decision making and behavior makes it harder for unethical behavior to go undetected. The many differences in culture around the world are reflected in different perspectives on what ethical behavior is. This is often reflected in difficulties that international companies face when doing business globally, sometimes leading to scandals because behavior that is considered ethical in one country may be considered unethical in another. See Ethical Behavior for more information about this.

Implications for Systems Engineering

As SE increasingly seeks to work across national, ethnic, and organizational boundaries, systems engineers need to be aware of cultural issues and how they affect expectations and behavior in collaborative working environments. SEs need to present information in an order and a manner suited to the culture and personal style of the audience. This entails choices like whether to start with principles or practical examples, levels of abstraction or use cases, the big picture or the detailed view.

Sensitivity to cultural issues is a success factor in SE endeavors (Siemieniuch and Sinclair 2006).

-

This knowledge area focuses on enabling a team to perform SE. Once that is done using the techniques described here, the knowledge found in Part 3, Systems Engineering and Management, about how to perform SE can be applied. Part 5, Enabling Systems Engineering, to which this knowledge area belongs, explores how systems engineering (SE) is enabled at three levels of organization: the business or enterprise, the team, and the individual.

For the sake of brevity, the term “business” is used to mean “business or enterprise” throughout most of this knowledge area. For a nuanced explanation of what distinguishes a business from an enterprise, see Enabling Systems Engineering.

Topics

Each part of the SEBoK is composed of knowledge areas (KAs). Each KA groups topics together around a theme related to the overall subject of the part. This KA contains the following topics:

- Team Capability
- Team Dynamics
- Technical Leadership in Systems Engineering

Overview

Products, enterprise systems, and services are developed, delivered, and sustained with the contributions of systems engineers, who also coordinate the technical aspects of the multiple projects that comprise a program. These activities require certain individuals to work in a cooperative manner to achieve shared objectives based on a common vision—that is, as teams. Not every group of individuals working together is a team. To perform SE activities efficiently and effectively, the capabilities of and dynamics within the team must be specifically attuned to SE.

Although individuals sometimes perform SE activities, it is more usual to find project teams performing SE activities while providing specialty engineering capabilities (see Systems Engineering and Specialty Engineering). Not all who perform SE activities are labeled “systems engineers.” Thus, electrical, mechanical, and software engineers, service providers, or enterprise architects in IT organizations may lead or be members of teams that perform SE tasks. Those individuals are referred to as systems engineers in this knowledge area, regardless of their job titles within their

organizations.

This knowledge area is concerned with methods, tools, and techniques for enabling project teams to perform SE activities. Its first topic, Team Capability, answers the questions:

- How do businesses determine value added by SE activities performed by project teams?
- How does an organization determine the efficiency and effectiveness of SE activities performed by project teams?

Its other topic, Team Dynamics, answers the question:

- How are group dynamics crucial to enabling systems engineers to perform work and achieve goals?

Topics from elsewhere in the SEBoK that cover related questions include Relationships between Systems Engineering and Project Management and The Influence of Project Structure and Governance on Systems Engineering and Project Management Relationships, which answer the question:

- What do managers need to know about managing systems engineers and project teams that perform SE activities?

Team Capability

- Lead Author:
- Dick Fairley
- Contributing Authors:
- Alice Squires, Art Pyster, and Heidi Davidz

-

The capability of a team to perform systems engineering (SE) depends on having competent personnel, adequate time, sufficient resources and equipment, and appropriate policies and procedures (Torres and Fairbanks 1996).

The team should have a charter. Staff must be proficient in the needed competencies and must work together with the right attitude, under the right organization, and with appropriate tools, training, and processes such as configuration management and peer review.

Those responsible for the team attaining the desired capability need to organize, staff, develop, and assess the team. Techniques for pilot projects, post-mortem analysis, and lessons learned can be applied as well.

Organizing the Team

Project teams, and the roles of systems engineers within those teams, depend on factors such as the nature, size, and scope of the project, the organization's preferred way of organizing teams, and external constraints such as a larger program in which the project may be embedded. Options range from a dedicated team of systems engineers, to Integrated Product Teams, to teams that include other kinds of engineers that perform systems engineering.

Systems engineers and SE teams may play the roles of technical leads, consultants, or advisers; this influences the ways in which SE teams are organized. In some organizations, systems engineers and SE teams provide technical leadership; they perform requirements analysis and architectural design, conduct trade studies, and allocate requirements and interfaces to the various elements of a system. In addition, they work with component specialists, develop integration plans and perform system integration, verification, and validation. Depending on the scope of effort, they may also install the system and train the operators and users; provide ongoing services to sustain the system; and retire/replace an aged system. Systems engineers may be housed within a functional unit of an organization and assigned, in matrix fashion, to projects and programs, or they may be permanently attached to a project or program for the duration of that endeavor. They may be organized based partially on their domain of expertise, such as finance or telecommunications. For additional information on organizational options see Determining Needed Systems Engineering Capabilities in Businesses and Enterprises.

In other cases, one or more systems engineers may provide consulting or advisory services, as requested, to projects and programs. These engineers may be dispatched from a central pool within an organization, or they may be hired

from an outside agency.

An SE team can be organized by job specialization, where each SE team member (or each SE sub-team) plays a different role; for example, requirements engineering, system architecture, integration, verification and validation, field test, and installation and training In this case the various job specializations are typically coordinated by a lead systems engineer.

Alternatively, an SE team can be organized by subsystem where each SE team member (or SE sub-team) performs the previously indicated functions for each of the subsystems with a top-level team to coordinate requirements allocation, interfaces, system integration, and system verification and validation.

Ideally, roles, responsibilities, and authority will be established for each project or program and used to determine the optimal way to organize the team. Sometimes, however, an *a priori* organizational, project, or program structure may determine the structure, roles, responsibilities, and authority of the SE team within a project or program; this may or may not be optimal.

Within a project, a systems engineer or SE team may occupy a staff position subordinate to the project manager, as indicated in Figure 1 or conversely, the SE team may provide the authoritative interface to the customer with the project manager or management team, serving in a staff capacity, as indicated in Figure 2. In both cases, SE and project management must work synergistically to achieve a balance among product attributes, schedule, and budget. Eisner (2008) lays out various approaches to organizing systems engineers. For additional information see Systems Engineering and Project Management.

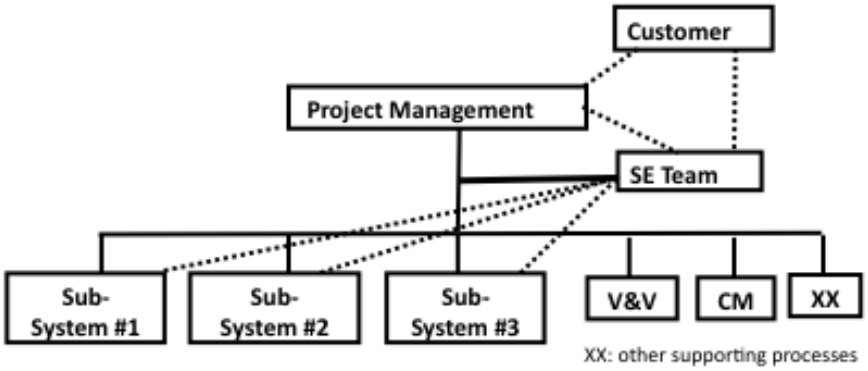

Figure 1. SE Team Subordinate to Project Management. (SEBoK Original)

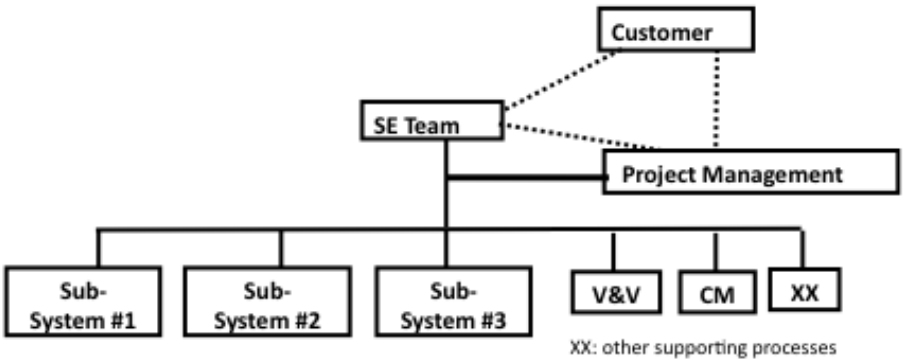

Figure 2. Project Management Subordinate to Systems Engineering. (SEBoK Original)

In scaling up to the program level, the considerations portrayed in Figures 1 and 2 can be generalized so that a top-level SE team provides coordination among the subordinate projects. In this case, each project has an SE team, and within each project the SE team members can be organized in either of the ways indicated in the figures. When scaling up to programs, each of the sub-systems in Figures 1 and 2 are separate, coordinated projects.

The models presented in Figures 1 and 2 can be scaled down to smaller projects, where an individual systems engineer performs the SE activities, either in the subordinate position of Figure 1 or the superior position of Figure 2. In this case, there is a single subsystem (i.e., the system) and the supporting functions may be provided by the systems engineer or by supporting elements of the larger organization.

The roles to be played by members of a SE team are influenced by the structures adopted as part of the organizational strategy of the business in which the team is operating (see Systems Engineering Organizational Strategy). In Product Centered Organizations, for example, an Integrated Product Team (IPT) is assigned to each element of the system breakdown structure (SBS). Each IPT consists of members of the technical disciplines necessary to perform systems engineering functions for that element of the system.

At the program level there is a top-level IPT commonly called a SE and integration team (SEIT), whose purpose is to oversee all of the lower level IPTs. Some specialists, such as reliability and safety engineers, may be assigned to a team to cover all elements within a given level of the SBS. These teams are sometimes called Analysis and Integration teams (AITs), and are created at various levels of the SBS as needed.

Organizing communication and coordination among a group of systems engineers should follow the well-known 7 ± 2 rule because the number of communication paths among N engineers is $N(N-1)/2$; i.e., the number of links in a fully connected graph (Brooks 1995). There are 10 communication paths among 5 engineers, 21 among 7 engineers, and 36 among 9 engineers. An SE team of more than 10 members (45 paths) should be organized hierarchically with a top-level team leader. Sub-teams can be partitioned by product subsystem or by process work activities (analysis, design, integration).

Staffing the Team

Once the organizational structure of the SE team is understood, the team can be staffed. As noted in Enabling Individuals, competency of an individual is manifest in the knowledge, skills, abilities, and attitudes needed for the individual to perform a specific task efficiently and effectively. Different levels of competency may be needed in different situations. Competencies include occupational competence, social competence, and communication competence. Competent systems engineers, for example, have SE knowledge, skills, and ability; engage in systems thinking; possess emotional intelligence; and have good communication and negotiation skills. In addition,

competent systems engineers are typically competent within specific domains (e.g. aerospace, medicine, information technology) and within specific process areas of systems engineering (e.g., requirements, design, verification and validation). (See Part 3, Systems Engineering and Management for more information on specific process areas.) The article on Roles and Competencies includes a summary of SE competency models. Based on the context, these competency models are tailored to match the needs of each project. The roles within the team are defined, and competencies are linked to the roles. The lists of competencies given in those models are most often distributed among the members of a SE team. It is not often that a single individual will possess the full list of competencies given in these models.

In addition to individual competencies to perform SE roles, the collective SE competencies needed by a team depend on additional factors including the domain, the stakeholders, the scope of the effort, criticality of outcome, new initiative versus enhancement, and the responsibilities and authority assigned to the team. For example, collective SE competencies needed to develop the IT enterprise architecture for a small company are quite different from those needed to develop the architecture of an aircraft which is engineered and manufactured in a distributed fashion around the world.

To determine the collective set of competencies an SE team needs to conduct a project or program, perform the following steps:

1. Identify the context, to include:
    1. domain
    2. stakeholders
    3. organizational culture
    4. scope of effort
    5. criticality of the product, enterprise endeavor, or service
    6. new initiative or sustainment project
2. Clarify the responsibilities, authority, and communication channels of the systems engineering team
3. Establish the roles to be played by systems engineers, and other project personnel as determined by context, responsibilities, and authority
4. Determine the required competencies and competency levels needed to fill each of the systems engineering roles
5. Determine the number of systems engineers needed to provide the competencies and competency levels for each role
6. Determine the availability of needed systems engineers
7. Adjust based on unavailability of needed systems engineers
8. Organize the systems engineering team in a manner that facilitates communication and coordination within the SE team and throughout the project or program
9. Consult stakeholders to ask “What are we missing?”

Competency models and skills inventories, such as INCOSE (2010) and Curtis et al. (2001), can be used as checklists to assist in determining the needed competencies and competency levels for a product, enterprise, or service. (See Roles and Competencies.)

When the needed competencies, competency levels, and capacities have been determined, one of two situations will arise: In the optimal situation, the number of systems engineers who have the needed competencies and competency levels to fill the identified roles will be available; or, they will be unavailable or cannot be provided because of insufficient funding. For example, a new initiative may need a lead engineer, a requirements engineer, a systems architect and a systems integrator-tester to accomplish systems engineering tasks. Budgetary constraints may indicate that only two of the four roles can be supported. Compromises must be made; perhaps the system architect will be the lead engineer and the requirements engineer will also be assigned the tasks of system integration and testing despite lacking the desired level of skill and experience (i.e., competency level) in integration and testing.

Developing the Team

Before a team that performs SE can be effective, it needs to establish its own identity, norms, and culture. The well-known four stages of *"forming, storming, norming, performing"* (Tuckman 1965, 384-399) indicate that a SE team needs time to form, for the members to get to know and understand each other as well as the tasks to be performed, and to work out how best to work together. It is also important that care is taken to ensure, to the greatest extent possible, assignment of roles and responsibilities that would allow SE team members to satisfy their individual goals (Fraser 2010).

The *cost and time to cohesion* can be minimized by good selection and management of the SE team, consistent training across the business so that team members have a common framework of understanding and language for their work, good "infostructure" to allow easy and useful sharing of information, and shared behavioral norms and values. Conversely, in cross-site, inter-company and international SE teams, more time must be allowed for team formation. SE teams are more effective if attention is given to ensuring that each member's work satisfies their individual goals as well as the team and organizational objectives (Fraser 2010).

According to Stephenson and Weil (1992), capable people are:

> *those who know how to learn; are creative; have a high degree of self-efficacy, can apply competencies in novel as well as familiar situations; and work well with others. In comparison to competency, which involves the acquisition of knowledge and skills, capability is a holistic attribute.*

The results of a survey by Steward Hase (2000) concluded that the following are significant contributors to the human elements of capability:

- Competent People
- Working in Teams
- Visible Vision and Values
- Ensuring Learning Takes Place
- Managing the Complexity of Change
- Demonstrating the Human Aspects of Leadership
- Performing as Change Agents
- Involving People in Change
- Developing Management Talent
- Committing to Organizational Development

These attributes of human capability apply to all members of an organization, including systems engineers, both as individuals and as members of project teams.

DeMarco and Lister (1999) discuss "teamicide" techniques by which management, perhaps unintentionally, practices *sure fire techniques to kill teams*. Teamicide techniques include

- physical separation of team members
- fragmentation of time
- unrealistic schedules
- excessive overtime

Methods for developing and improving SE capabilities within teams include building cohesive teams, conducting pilot projects, participating in and studying post-mortem analyses, and preparing and examining lessons learned. Members of a cohesive systems engineering team have a strong sense of commitment to the work and to the other team members. Commitment creates synergy, which results in performance greater than the sum of the performance of the individual team members.

Some key indicators of a cohesive systems engineering team (Fairley 2009, 411) are:

- clear understanding of systems engineering roles and responsibilities
- shared ownership of systems engineering work products

- willingness of systems engineers to help one another and to help other project members
- good communication channels among systems engineers and with other project elements
- enjoyment of working together

Negations of these indicators—the hallmarks of a dysfunctional team—are:

- confusion of systems engineering roles and responsibilities
- protective ownership of systems engineering work products
- unwillingness to help one another
- absence of good communications among systems engineers and with other project elements
- personal dislike of one or more other systems engineering team members

Techniques for building and maintaining cohesive systems engineering teams include:

- an appropriate number of systems engineering team members
- a correct mix of systems engineering competencies
- celebration of project milestones
- team participation in off-site events
- social events that include family members

Assessing the Team

Performance evaluation is most often conducted for individuals. Robbins (1998, 576) states the historic belief that individuals are the core building blocks around which organizations are built. However, it is also important to assess the team's capability and performance. To design a system that supports and improves the performance of teams, including SE teams, Robbins offers four suggestions:

1. Tie the SE team's performance and the overall project team's results to the organization's goals
2. Begin with the team's customer and the work process the team follows to satisfy customer's needs
3. Measure both team and individual performance and compare them to organizational norms and benchmarks
4. Train the team to create its own measures

Robbins' approach can be applied in the context of SE:

1. Tie the SE and overall project team's results to the project's and the organization's goals. Use measures that apply to goals the team must achieve. For SE in particular, the team effort should be tied to the product or service which the organization seeks to deliver. The end product for the SE team should not be only the SE work products but the delivered products and services provided by the project. For more information on general SE assessment, see Systems Engineering Project Assessment and Control.
2. Consider the SE team's customers and more broadly the key stakeholders and the work processes that the SE team follows to satisfy customer needs. SE customers and stakeholders can be internal or external; the internal customers of systems engineering are the other project elements that depend on systems engineering work products and services, which can be evaluated for on-time delivery of quantity and quality. The process steps can be evaluated for waste and cycle time; i.e., efficiency and effectiveness.
3. Assess both individual and team performance. Define the roles of each SE team member in terms of the tasks that must be accomplished to produce the team's work products. For more information on individual assessment, see Assessing Individuals.
4. Finally, have the team define its own measures of achievement of goals. This helps all members of the team to understand their roles, while also building team cohesion.

As an example, NASA's Academy of Program/Project and Engineering Leadership (APPEL) provides a service where team performance is assessed and interventions are provided to the team for specific gaps in performance (NASA 2011). This performance enhancement service increases a project's probability of success by delivering the right support to a project team at the right time. APPEL offers the following assessments:

- Project/Team Effectiveness — Measures effectiveness of a team's behavioral norms
- Individual Effectiveness — Measures effectiveness of an individual's behavioral norms
- Project/Team Process Utilization — Measures the extent of a team's utilization of key processes
- Project/Team Knowledge — Covers topics that NASA project personnel should know in order to perform in their jobs

The APPEL approach can be applied to assessing the performance of a SE team and individual systems engineers.

Further Techniques for Building Team Capability

Further techniques for developing SE capabilities within teams include conducting pilot projects, preparing post-mortem analyses, and participating in and studying lessons learned.

Pilot Projects

Pilot projects are an effective mechanism by which SE teams can build team cohesion, acquire new skills, and practice applying newly acquired skills to projects and programs. Pilot projects can be conducted for the sole purpose of skills acquisition, or they can be conducted to determine the feasibility of a proposed approach to solving a problem. Feasibility studies and acquisition of new team skills can be combined in proof-of-concept studies. Primary inhibitors to conducting SE pilot projects are the time required and diversion of personnel resources.

Post-Mortem Analysis

A post-mortem analysis identifies areas for improvement of SE performance in future projects and programs. Inputs to a post-mortem analysis include:

- personal reflections and recollections of project personnel and other stakeholders;
- email messages, memos, and other forms of communication collected during a project or program;
- successful and unsuccessful risk mitigation actions taken; and
- trends and issues in change requests and defect reports processed by the change control board.

Team participation in a post-mortem analysis allows SE team members to reflect on past efforts, which can lead to improved team capabilities for future projects or, if the present team is being disbanded, improved individual ability to participate in future systems engineering teams.

Inhibitors for effective post-mortem analysis include failure to allocate time to conduct the analysis, failure to effectively capture lessons-learned, failure to adequately document results, reluctance of personnel to be candid about the performance of other personnel, and negative social and political aspects of a project or program. Mechanisms to conduct effective post-mortem analyses of SE projects include using a third-party facilitator, brainstorming, Strength-Weakness-Opportunity-Threat (SWOT) analysis, fishbone (Ishikawa) diagrams, and mind mapping.

Lessons Learned

Lessons learned in SE can be both positive and negative. Experiences gained and documented from past projects and programs can be an effective mechanism for developing and improving the capabilities of a team that performs SE tasks. Studying past lessons learned can aid in team formation during the initiation phase of a new project. Lessons learned during the present project or program can result in improved capabilities for the remainder of the present project and for future projects. Inputs for developing and documenting SE lessons learned include results of past post-mortem analyses plus personal recollections of the team members, informal *war stories*, and analysis of email messages, status reports, and risk management outcomes. Inhibitors for developing and using SE lessons learned include failure to study lessons learned from past projects and programs during the initiation phase of a project, failure to allocate time and resources to developing and documenting lessons learned from the present project or

program, and reluctance to discuss problems and issues.

Team Dynamics

- Lead Author:
- Dick Fairley
- Contributing Authors:
- Alice Squires and Art Pyster

-

A systems engineering (SE) team is a group of individuals who cooperatively perform a collection of SE tasks based on a shared vision and a common set of engineering objectives. Applying the practical considerations of group dynamics is essential to enabling SE teams to successfully perform SE activities. The interplay of the behaviors of humans in groups is varied, changing, and inescapable. Nevertheless, study of these behaviors has yielded valuable insight and knowledge on the dynamics of individuals within groups. The awareness and application of group dynamics is crucial to facilitating systems engineers' performance of work and achievement of their goals.

The study of group dynamics was initially within the province of psychology and later within sociology. The importance of group dynamics to successful teams has led other disciplines such as business management to study and apply team dynamics.

History

The origins of the study of group dynamics began with Gustave Le Bon. Le Bon wrote *La psychologie des fouls* in 1895, which was translated into English as *The Crowd: A Study of the Popular Mind* a year later. Sigmund Freud wrote *Group Psychology and the Analysis of the Ego* in 1922 responding to Le Bon's work. Kurt Lewin is acknowledged as the "founder of social psychology", coining the term **group dynamics**. He founded the Research Center for Group Dynamics at the Massachusetts Institute of Technology in 1945, relocating in 1948 to the University of Michigan. Wilfred Bion studied group dynamics from a psychoanalytical perspective. He helped found the Tavistock Institute of Human Relations in 1947. In that same year, both the Research Center for Group

Dynamics and the Tavistock Institute of Human Relations founded the journal *Human Relations*. The study of group dynamics is now worldwide, active, and well established.

Nature of Groups

Groups are endemic to human existence and experience; humans are by nature social animals. Consequentially, an informed understanding of the nature of groups is very useful in enabling teams to perform SE. Research into group behavior reveals that the nature of a group can be described by interaction, goals, interdependence, structure, unity, and stage. (Forsyth 2010, 5-10)

Interaction

Communication (both verbal and non-verbal) among members within a group produces constantly changing and varied interactions. Group dynamics are more than the sum of the interactions between individual members; group interactions create synergistic behaviors and results. Interactions can be placed into two categories (1) socio-emotional interactions and (2) task interactions (Bales 1950, 1999).

Goals

All groups exist for the purpose of achieving one or more goals. The goals provide the basis for the group's tasks. The tasks accomplished by the group can be categorized into activities and characterized by a Circumplex Model (McGrath 1984, 61), which establishes four quadrants, where the X-axis is *choose* vs. *execute* and the Y-axis is *generate* vs. *negotiate*.

Interdependence

Interdependence is *the state of being dependent to some degree on other people, as when one's outcomes, actions, thoughts, feelings, and experiences are determined in whole or in part by others*. Interdependence can be categorized into five types (1) mutual, reciprocal; (2) unilateral; (3) reciprocal, unequal; (4) serial; and (5) multi-level. (Forsyth 2010, 8)

Structure

Structure includes the organization and patterned behaviors of a group. Structure can be deliberately devised and/or emergently observed. Most groups have both kinds of structures, which are evinced in the roles and norms of the group. *The roles of leader and follower are fundamental ones in many groups, but other roles — information seeker, information giver, elaborator, procedural technician, encourager, compromiser, harmonizer — may emerge in any group* (Benne and Sheats 1948; Forsyth 2010, 9). Norms are the rules that govern the actions of group members; norms can include both formal and informal rules.

Cohesion

The *interpersonal forces that bind the members together in a single unit with boundaries that mark who is in the group and who is outside of it* constitute a group's cohesion (Dion 2000). Cohesion is an essential quality of group; it can vary from weak to strong. A team cannot perform effectively without strong group cohesion.

Stage

Groups exhibit stages of development. Being comprised of people, it is not surprising that groups collectively demonstrate the dynamics and growth of the individuals that constitute the group members. The most well-known and wide-spread model of the stages of group development was developed by Bruce Tuckman. The initial model identified the sequence of group development as (1) Forming, (2) Storming, (3) Norming, and (4) Performing

(Tuckman 1965). He later added a final stage to the model: (5) Adjourning (Tuckman and Jensen 1977). While Tuckman's model is sequential, others have observed that groups may actually recursively and iteratively progress through the different stages (Forsyth 2010, 20).

Practical Considerations

The dynamics associated with creating, nurturing, and leading a team that will successfully achieve the team's goals is important and challenging. Although psychologists and sociologists have conducted and continue to conduct research to understand team dynamics, the profession of business management has additionally sought to develop practical guidance for utilizing and applying this knowledge to foster high-performance teams. Accordingly, business management has focused its contribution to the field of team dynamics by publishing practical guidebooks to analyze the problems and focus on developing solutions to the problems of team dynamics (see Additional References). There are many consultancy firms throughout the world that assist organizations with the application of practical knowledge on team dynamics. Successful systems engineering teams would do well to not ignore, but rather take advantage of this knowledge.

Diversity, Equity, and Inclusion

- Lead Authors:
- Alan Harding and Alice Squires

-

Diversity, Equity, and Inclusion (DEI) foster increased engagement, productivity, and innovation in an organization.

DEI in Systems Engineering

Systems engineers play a pivotal role in integrating concepts of diversity, equity, and inclusion within the teams they work on and in system design and development. In particular, systems engineers should:

1. Ensure that the systems engineering team and its leadership is inclusive and welcomes a diverse range of talent, and where necessary taking deliberate action to provide equity.
2. Ensures that the systems we realise are as accommodating as possible of the differences within the entire stakeholder community. This is known as “inclusive engineering”.

Failure to address either aspect can result in sub-optimal outcomes whether in terms of missed solutions, lower productivity, or delivering a system that does not fully meet the needs of the whole stakeholder community, i.e. failing to meet the ultimate goal of delivering a total optimal system solution.

Systems engineers are responsible for effectively communicating the importance and value of diversity, equity, and inclusion in enabling, promoting, and advancing systems engineering and systems approaches to address complex societal and technical global challenges.

Figure 1 shows how an inclusive development approach contributes to realizing inclusive solutions, within the context of the human system (whether within an organisation, country, or the world), itself set within the context of the natural world. The natural world is shown because of the strong linkage between the full lifecycle of engineered products (from concept to disposal) and sustainable development. For instance:

- Water pollution from industrial plants affecting those who live nearby
- Air pollution from cars affecting pedestrians and those who live near major roads
- Product end of life/disposal effects e.g. hazardous substances, contribution to land-fill

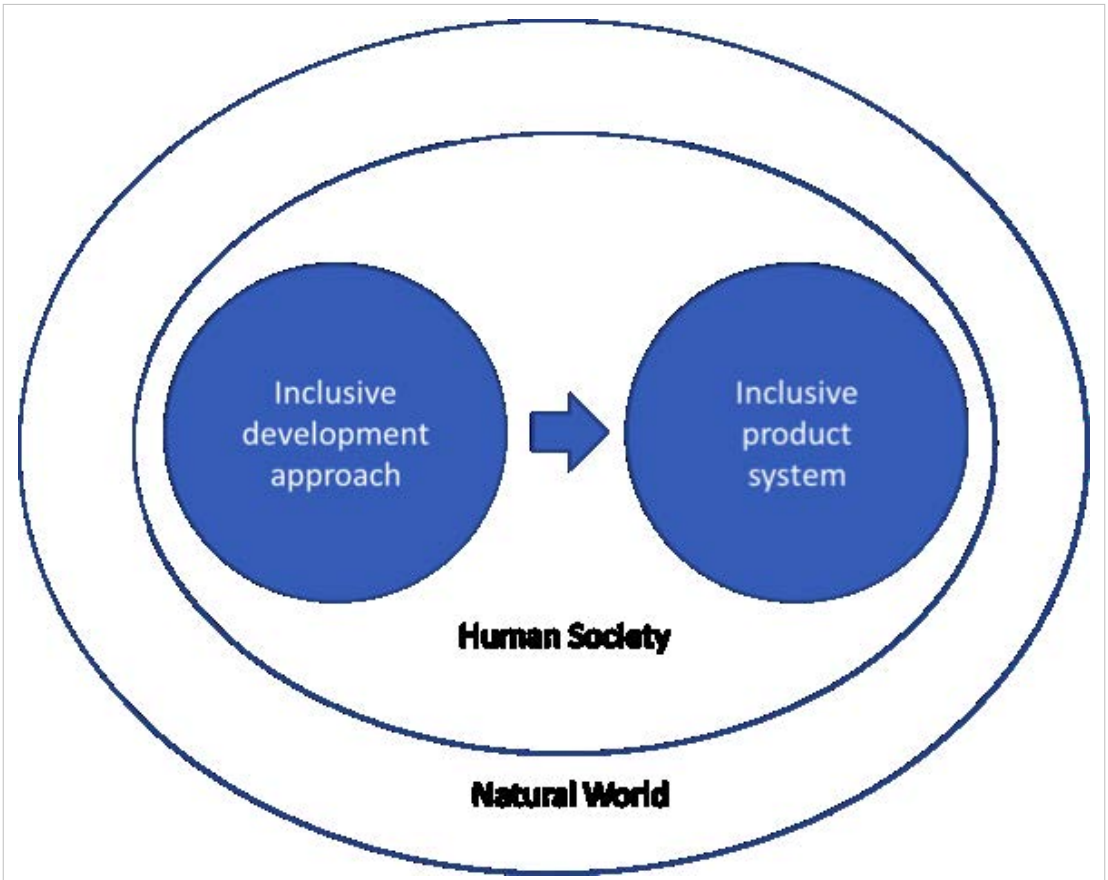

Figure 1. Relationship between Inclusive Approach and Inclusive Product. (SEBoK Original)

Definitions of Diversity, Equity, and Inclusion

The following definitions are taken from the Accreditation Board for Engineering and Technology (ABET 2020), where they provide a reference point for conversations and materials about diversity, equity and inclusion.

- Diversity is the range of human differences, encompassing the characteristics that make one individual or group different from another. Diversity includes, but is not limited to, the following characteristics: race, ethnicity, culture, gender identity and expression, age, national origin, religious beliefs, work sector, physical ability, sexual orientation, socioeconomic status, education, marital status, language, physical appearance, and cognitive differences.
- Equity is the fair treatment, access, opportunity and advancement for all people, achieved by intentional focus on their disparate needs, conditions and abilities. Achieving equity requires understanding of historical and systemic patterns of disparity to address and eliminate barriers, and remove participation gaps as part of a comprehensive strategy to achieve equitable outcomes and social justice.
- Inclusion is the intentional, proactive, and continuing efforts and practices in which all members respect, support, and value others. An inclusive environment provides equitable access to opportunities and resources, empowers everyone to participate equally, and offers respect in words and actions for all.

Commonly, the compound term "Diversity, Equity and Inclusion" (abbreviated to DEI) is used to refer to the broad subject area. The definition of diversity given encompasses a wide range of characteristics. As an example, Figure 2 shows 28 of these characteristics recognised by the International Council on Systems Engineering (INCOSE) (Harding and Pickard 2019) grouped into five areas: intrinsic, employment, environment, interaction, and family. The figure shows the relevance of these characteristics to the INCOSE Systems Engineering Certification Program.

Figure 2. Categorized Dimensions of Diversity. (SEBoK Original, adapted from (Harding and Pickard 2019))

Relevance of Diversity, Equity, and Inclusion to Engineering

Engineers apply ingenuity, innovation, and systematic approaches to solve challenging problems. Life experience and academic research shows us that bringing a wide range of skills, knowledge, and thinking styles to bear on a problem is the most effective way to accelerate and improve the intended outcomes. These outcomes include improved "…financial performance, greater innovation and creativity, increased employee productivity and retention, improved customer or client orientation, and increased customer or client satisfaction." (Royal Academy of Engineering 2015). Hunt et al. (2018) have found that companies at the forefront of gender and ethnic/cultural diversity in their leadership perform better financially.

By contrast, a team of people with the same cultural background, life experiences, education, and thinking style could be expected to be relatively less effective and more prone to identifying predictable solutions. The US National Academy of Engineering (2002) notes the opportunity cost of a lack of diversity in terms of "designs not thought of, in solutions not produced."

Inclusion, or ensuring a sense of inclusion in everyone, is necessary to ensure that all team members genuinely feel and believe that they belong and hence are able to use their talents and unique outlook to the maximum degree. By contrast, a lack of inclusion might make someone feel present but not involved or valued with the effect that the team as a whole does not deliver its best possible results.

Equity is not the same as equality, nor is it the same as inequality. It is simply giving more to those who need it, which is proportionate to their own circumstances, in order to ensure that everyone has the same opportunities. In an engineering context this might mean providing more support to a disadvantaged student so they can reach their full potential, or providing additional support or time to a team member with a condition such as dyslexia.

Relevance of Diversity, Equity, and Inclusion to Systems Engineering

DEI is vital to successful systems engineering because of the range of contexts in which it is applied and the consideration of multiple stakeholder viewpoints at the heart of the approach. Systems engineering is applied to a wide range of system types in a broad variety of contexts–engineered systems range from microelectronics to aircraft, from abstract systems to smart cities. Systems engineers may be working with a customer, a prime contractor or integrator, a supplier or product manufacturer, a research/technology organisation, or a government body. And these activities take place all over the globe, often as part of consortiums or complex partnered programmes involving multiple organisations, countries, and cultures.

Applying systems engineering requires consideration of multiple viewpoints (such as the user, maintenance, safety, security) to achieve the proper holistic view of problem and solution. This means that the systems engineering team must be able to understand and work with a wide range of stakeholders. The transdisciplinary and integrative nature of systems engineering across other disciplines and activities, again, means that the systems engineering team needs to understand and work well with all the disciplines and specialities involved in realising a system (INCOSE 2020).

Given this diversity of context and of types of systems engineered, and the wide range of stakeholders with whom they need to work, systems engineering workforce and culture should be at the forefront of DEI. In this way, we can represent as many aspects of the diverse community and their needs as possible within the team, and the diverse nature of the team also creates the innovation from which we can realise the best solutions.

Like most of engineering, systems engineering was historically not practiced by a diverse group of people. Therefore, it is necessary to apply the notions of equity (as defined) in order to ensure that the widest range of people are enabled and empowered to become and develop as systems engineers.

Inclusion (as defined) is about ensuring that the whole (diverse) team is engaged, supported and feels safe and able to give of their best to the team's activity. An inclusive team will produce increased productivity and better-quality outcomes than the alternative. It also provides increased potential for inclusive products because of the greater range of stakeholder views within the team.

Inclusive Engineering

Inclusive Engineering (Inclusive Engineering, n.d.) is the discipline of ensuring that engineering products and services are accessible to and inclusive of all users and are as free as possible from discrimination and bias. This should consider as far as possible all human differences (characteristics of diversity). It is a way of ensuring that engineering is appropriate, ethical, accessible, and as risk free as possible. The extent to which an engineered system is inclusive reduces the degree to which adaptation has to be applied to address the needs of people with differences e.g., differing vision, differing strength or motor functions.

In their enthusiasm for solutions engineers often do not stop to think about whether they have considered all of the things that impact on their design – and in particular all of the non-technical requirements that are not specified by the client or potential beneficiary. As a result, proposed solutions often lack the perspectives of people who have not been involved in their development – and in an industry which is notoriously lacking in diversity – this often means that they fail to include the perspectives of women, people with disabilities, the ageing population, and those with other under-represented characteristics.

Figure 3 shows an inclusive engineering framework (ref. 8) which has eight elements, all of which are important factors for systems engineers to address even if the stated requirements do not cover them.

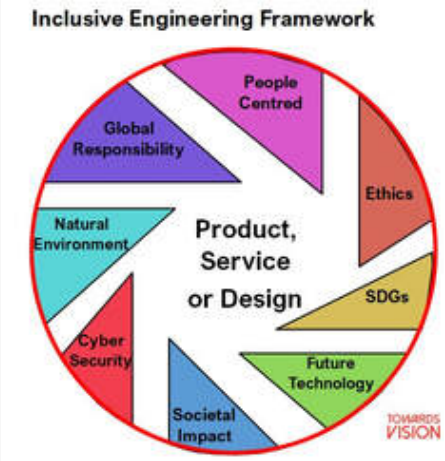

Figure 3. Inclusive Engineering Framework
(Used with Permission, (Bonfield 2021), http://www.inceng.org/inclusive-engineering-framework.html [1])

One way that systems engineers can maximise the potential for inclusive and sustainable solutions is to ensure that DEI considerations are through application of the ISO/IEC/IEEE 15288:2015 Technical Processes. Table 1 illustrates the application of Inclusive Engineering these processes.

Table 1. Mapping of the application of ISO/IEC/IEEE 15288:2015 Technical Processes to Inclusive Engineering considerations.

ISO/IEC/IEEE 15288:2015 Technical Process	Inclusive Engineering considerations
Business or Mission Analysis	• Ensure all stakeholders are identified, both the obvious (beneficial) stakeholders, and those potentially affected by the system and the associated project (referred to as “unwilling” stakeholders).
Stakeholder Needs and Requirements Definition	• Identify stated stakeholder needs and the unstated but necessary needs arising from inclusive design – e.g. access, language, disability. • Use understanding of Sustainable Development Goals, circular economies etc. to inform future-looking discussions about needs.
System Requirements Definition	• Ensure that inclusion considerations result in well-specified requirements drawing on standards and legislation as necessary. • Ensure that definition of the System Boundary is informed by its intended and unintended emergent effects on its wider context. • Facilitate careful trade-off and option analysis to optimise equitable outcomes.
Architecture Definition	• Ensure that all necessary Architecture viewpoints are considered to ensure that inclusion and sustainability factors can be given due consideration. • Ensure that Architectures are open to allow future technology adoption where beneficial during the system lifecycle.
Design Definition	• Ensure that technology choices and principles for design evolution are informed by Sustainable Development Goals, circular economies etc.
System Analysis	• Ensure that System Analysis includes the modelling and prediction of inclusive engineering and sustainable development factors, in particular modelling to understand key emergent outcomes.
Implementation	• Ensure that the design team is diverse, properly trained, and understands the principles of diversity, equity, inclusion, sustainability, circular economy, etc.
Integration	• Ensure that the integration process is safe, secure, and environmentally compliant.

Verification	• Ensure that planned verification activities fully address all aspects of diversity, equity, and inclusion for all relevant stakeholders and are safe, secure, and environmentally compliant.
Transition	• Ensure that transition plans fully cover all stakeholders and are safe, secure, and environmentally compliant, and that any temporary/transitional arrangements do not have accidental negative effects on unwilling stakeholders or the natural environment i.e., there is an equitable transition plan.
Validation	• Ensure that that planned validation activities fully address all aspects of diversity, equity, and inclusion for all relevant stakeholders including indirect/unwilling stakeholders and the natural environment and are safe, secure, and environmentally compliant.
Operations	• Ensure that selection and training for operations staff is sufficient that a diverse group of operators can correctly operate all aspects of the system such that the system remains safe, secure, and environmentally compliant.
Maintenance	• Ensure that selection and training for maintenance staff is sufficient that a diverse group of maintainers can correctly operate all aspects of the system such that the system remains safe, secure, and environmentally compliant. • Ensure that planned maintenance ensures that the system fully meets its initial specification throughout its service life e.g., energy use, emissions, pollution.
Disposal	• Ensure that selection and training for disposal staff is sufficient that a diverse group of staff can correctly dispose of hazardous materials such that the system remains safe, secure, and environmentally compliant. • Ensure that disposal of hazardous materials is carefully planned, and that recycling and reuse opportunities are maximised.

Technical Leadership in Systems Engineering

- Lead Author:
- Heidi Davidz

-

Leadership is an important but often overlooked component of technical projects and programs. It addresses the performance of people: their behaviors, their ability to think individually and collectively, and their motivation and energy. Technical leadership in systems engineering creates the environmental conditions conducive to good performance: support of shared understanding, innovation, problem solving, resilience and learning. Leadership is thus complementary to management, which directs specific activities to deliver outputs. A systems engineering leader may lead a team of systems engineers for a project or program, or may be the only systems engineer in a team of diverse members involved in project or program (e.g. other engineers, IT personnel, service providers). There are various models and styles of leadership and key to success is matching leadership to the needs of a situation. “‘Models’” of leadership describe the mechanisms by which leadership arises and operates (e.g. situationally-driven or caused by a charismatic individual). “’Styles’” of leadership describe the manner in which a leader (or a leadership team) leads (e.g. task-focused or people-focused; autocratic, democratic or “laissez-faire” (Lewin et al., 1939)).

There is a vast amount of literature addressing leadership issues from multiple points of view, including philosophical, psychological and emotional considerations (Yukl, 2012). This article highlights key aspects of leadership theory to help systems engineers understand how they may influence the success of their team and organization. Leadership theory provides the basic building blocks for adapting leadership behaviors at work. The pragmatic aspects of leading team members involved in systems engineering are summarized in section 1.11. This section highlights the need to use different approaches to leadership across the systems engineering context, and it is therefore important be able to understand and adopt the leadership behaviors discussed in the preceding sections, as judged appropriate. Related knowledge areas and articles are in the Part 5 Knowledge Area Part 5 Enabling Systems Engineering and the Part 6 Knowledge Area Systems Engineering and Project Management.

Attributes of Effective Leaders

Traditional Attitudes to Technical Leadership

The need for leadership in an engineering environment has not been widely emphasized or understood. Traditional academic engineering curricula do not cover the development of leadership skills, and industry professionals tend to be task-oriented, with project leaders perceived in terms of power and authority (Toor and Ofori, 2008). In many cases, technical organizations focus on management rather than leadership. “Managers are people who do things right while leaders are people who do the right thing” (Bennis and Nanus, 1985). Doing the right thing is not only about identifying the right approach in the first place; it is also about taking responsibility for understanding and

challenging the progression of a project or program in a continuous manner. It is now recognized that leadership is a critical component of successful projects and programs, and that technical leadership is likely to be a distributed responsibility.

Great Man Theories: Traits and Charisma Models of Leadership

Early concepts of leadership were driven by views of leaders as heroic figures, with particular qualities that made them different to other people. The notion of "charisma" was used to describe the ability to charm and influence followers. Numerous studies have been conducted to try and define the particular personality traits that made someone a born leader. The findings are not clear-cut, partly because there are many different models of personality which produce different results (Hippocrates first identified 4 personality dimensions in the 5th Century BC, and many different conceptualizations have been devised since then). Personality tests should be used with great caution because each test has been developed for specific purposes and contexts, and is only valid within those parameters. For tests to be valid they must undergo a strict set of tests with extensive data sets, and then they must be used exactly as specified by the validation process. The current best consensus of evidence is that there are 5 main dimensions of personality: '"Extraversion"' (talkative, sociable); '"Agreeableness"' (good natured, co-operative); '"Conscientiousness"' (responsible, tidy); '"Neuroticism"' (general level of anxiety or composure); and '"Openness"' (to new experiences). This 5-Factor model has good validity across literate populations, but even this model may not be universal (Gurven at al., 2013). There is some evidence that extraversion is associated with leadership roles, but this is not always a predictor of success, and may reflect a cultural stereotype which leads to people who behave like leaders being more likely to get leadership roles. Different contexts will change the value of extraversion (and other traits) in a leader. (See Judge et al. (2002) for a meta-analysis of the literature).

In business settings, the Myers-Briggs Type Indicator (MBTI) personality test is often used as part of guided discussions to assist with self-development (although it lacks the important personality dimension of 'neuroticism'). People can use their MBTI profiles to help them use their strengths more effectively. Occasionally, MBTI is misused as a basis for selection, especially for leadership roles. The evidence indicates this is not justified (National Research Council, 1991).

Transactional and Transformational Leadership Styles

Certain behaviors have been associated with successful leadership. These behaviors arise from the style of leadership and particularly the attention paid to the task compared to team relationships. Such differences are described as transactional and transformational styles (Burns, 1978). Transactional leadership is closely allied to management, focused on defined task outputs and incentivizing people to follow directions by rewarding and punishing.

Transformational leadership is concerned with achieving outcomes through the development of the people (team building), building trust, developing a shared vision, motivation, cultivating relationships and sharing knowledge. Both types of leadership have value, but transformational leadership is needed for developing the culture of an organization, and for ensuring qualities such as safety, adaptability, learning and improvement. It is usually considered the most valuable form of leadership.

Understanding that different styles have value for different situations provides the basis for leadership models that recognize the interactions between style and situation. Fiedler's Contingency Model, Hersey et al.'s Situational Model and House's Path-Goal Theory (all described below) provide useful variations on this approach.

Contingency Model of leadership

Fielder's Contingency Model (1964) states that there is no one best style of leadership. Effectiveness is about the match between leadership style (defined as task or relationship-oriented) and situation (defined by: the degree to which the leader is supported by the group; the degree to which the task is clearly structured; and the degree to which the leader can reward and punish team members). Fiedler devised a way of assessing leaders' styles by measuring their attitude to their 'least preferred co-worker' or LPC. In general terms, leaders who are more negative about their LPC are task-oriented and focus on organizing. Leaders who are more positive towards their LPCs are more able to avoid conflict, promote innovation and learning and are better at making complex decisions. In moderate situations (not extreme in any of the three situation dimensions), the more positive, relationship-oriented leaders appear to be more successful (Valle & Avella, 2003). This contingency model of leadership was found to predict leadership style in an information systems engineering environment, where leadership functions were distributed across technical experts and the end-user (Franz, 1985).

Situational Theory

Situational Theory offers a model of leadership in which any individual leader adapts his or her style according to the needs of the situation. For example, they can learn to change from being task-focused to being relationship focused. They may also adapt according to their own changing status. Hersey, Blanchard and Johnson (2001) describe four modes that leaders can adapt between, according to the nature of the members of the team or organization: delegating, supporting, coaching, and directing. In this situational model, leadership is a learned skill based on understanding context and self-awareness.

Path-Goal Model

The Path-Goal Theory describes the leader's role as helping followers to develop behaviors that allow them to achieve their goals (House and Mitchell, 1974). Leaders are facilitators for others' achievements, e.g. providing resources, associations, knowledge and support. Leaders are members of a community of practice united in a common enterprise and sharing a common culture: history, values, ways of doing things, and ways of talking (Drath and Palus, 1994). In technical leadership, this means helping technical followers to perform effectively in their tasks, and in systems engineering this means facilitating pathways of communication between different areas, encouraging attitudes and behaviors that promote integrated perspectives.

Authentic Leadership

Somewhat in contrast to the principle of leading by adapting style, and thus in effect "acting the part", research on leaders being "authentic" evaluates the effectiveness of staying true to one's own natural style. Successful authentic leaders are described as positive, leading from the heart, concerned with ethics, building on trust, motivating people to achieve challenging tasks. According to the authentic leadership literature (e.g., Gardner et al., 2011; Walumbwa et al., 2008), authentic leaders display four types of behaviors. These include balanced processing (taking evidence from all sides), internalized moral perspective (driven more by morality than external pressures), relational transparency (openly sharing thoughts and feelings), and self-awareness (understanding of self and how others view them) (Gardner et al., 2011). These behaviors are likely to lead to a team having trust in the leader, which will be important in a technical context where safely achieving the right outcome= in a complex situation is paramount.

Allied to authentic leadership in terms of behaviors is the concept of Servant Leadership, described as having seven key practices: self-awareness; listening; inverting the pyramid (leadership hierarchy); developing your colleagues; coaching, not controlling; unleashing the energy and intelligence of others; and foresight. Keith (2012), and Sipe and Frick (2009) have a similar list: servant leaders are individuals of character, put people first, are skilled communicators, are compassionate collaborators, use foresight, are systems thinkers, and exercise moral authority.

The servant leadership elements of Empowerment, Standing Back / Sharing Credit, Courage / Risk Taking, Humility, Authenticity, and Stewardship were shown to have a statistically significant correlation with innovation output from engineering teams when applied at a frontline team leadership level (McCleave and Capella, 2015).

Complexity Leadership and the Leadership Process

Authentic and servant leadership styles place a leader in the role of a facilitator, rather than a director; someone who can leverage the capabilities of the team and create synergistic benefits. This perspective is taken a step further in the model of leadership that comes from complexity theory.

Complexity Leadership describes leadership as promoting emergent adaptive outcomes from organizations (such as learning and innovation). Organizations are considered to be complex adaptive systems and leadership can take three forms: administrative, adaptive and enabling. Each form will vary itself according to its locus in an organizational hierarchy. The complex adaptive functions provide the adaptive capability while the bureaucratic functions provide the coordinating structures. Leadership should disentangle these two types of functions in a way that enhances the effectiveness of the organization (Marion & Uhl-Bien, 2001). In this model, leadership is mostly about developing interactions.

Complexity leadership is differentiated from leaders as individuals, because in some cases leadership is about a function rather than a person. In a technical situation such as a Systems Engineering team, this will be an important consideration, as different people will have technical expertise and will be required to provide leadership in areas such as understanding, challenging and communicating. Systems engineering teams consist of members from diverse disciplines with diverse interests. Silos of self-interest must be broken down (or at least effective communication among silos must be established and a balance between global system concerns and provincial disciplinary interests must be maintained.)

Manz and Sims (1989) also see leadership as a process, but they focus on self-leadership within each individual more than the behaviors and actions of a few select people designated as formal leaders in an organization. With this perspective, most people have some contribution to leadership.

Followership

Equally important is the concept of followership. A leader can only lead with effective followers. In technical situations, where a distributed process of leadership may be needed, this is especially important. The study of followership is much less developed than that of leadership, although they are two sides of the same coin. Uhl-Bien et al. (2014) have conducted a review of the literature to date and identify two theoretical frameworks for understanding followership: a role-based approach and a process approach. They warn against too much focus on a leader role and not enough on the leadership process, and suggest that understanding followership can help with:

- Recognizing the importance of follower roles, following behaviors, and the leadership process
- Understanding leadership processes and its outcomes as a function of leaders and followers
- Identifying effective followership behaviors
- Embedding context in the leadership process
- Recognizing that leadership can flow in all directions
- Understanding why and how managers are not always able to co-construct leadership with their subordinates
- Developing followership

This perspective is supportive of a distributed leadership function and is helpful for supporting people who have leadership roles as a consequence of their technical knowledge rather than their desire to lead or comfort with doing so.

Associated with followership development is the nature of motivation within the individuals that the leader wishes to influence. The term “motivation” has been used to describe a range of possible causes of behavior, and no single theory can explain all situations. A useful distinction, however, is the difference between “intrinsic” and “extrinsic”

motivation. The former relates to factors arising from emotions, ambitions, expectations and other internal states of an individual, and tends to be the focus of transformational leaders (see section 1.3). The latter relates to factors arising from external factors such as threats, rewards, and social pressure, and tends to be the focus of transactional leaders (also in section 1.3). It is important to recognize that there are cultural and professional differences in the strength of internal and external causes of motivation. One famous model of motivation by Maslow (1943), the "Hierarchy of Needs", is useful to assess a range of potential factors, but does not have scientific validity and is based on a rather narrow Western 20th Century perspective. For example, it does not explain why people are willing to undergo physical hardship to conquer higher level challenges; or why some cultures are collectivist while others are individualistic. (A useful review of these culture differences can be found in Triandis et al., 1988).

A more actionable approach to motivation emphasizes an individual's mental model of what is important (valence), what their own role is in achieving it (instrumentality), and how able they are to achieve it (expectancy). This was first described by Vroom (1964) and has led to the concept of 'empowering' individuals (e.g. Conger and Kanungo, 1988). The Path-Goal model of leadership (section 1.6) aims to facilitate performance by addressing these aspects of motivation. This approach to motivation, called Expectancy Theory, can help leaders understand how to motivate employees through challenge and self-belief (Isaac, Zerbe, and Pitt, (2001).

An attempt to understand motivation at the organizational level has led to the concept of "organizational energy" (Cole, Bruch and Vogel, 2005). According to the existing overall energy type in an organization, a leader should adopt a different motivational strategy to achieve the optimum "productive" energy, which is described as high intensity and positive. A resignative energy (low intensity, negative) requires the development of a vision, empowerment and challenge. A corrosive energy (high intensity, negative) requires better communication and the development of trust. A comfortable energy (low intensity, positive) requires the identification of an external threat.

Competencies

Leadership competencies are the knowledge and skills required by individuals and teams for making leadership effective. Sometimes traits and other individual differences are added to skills and knowledge to create a "Competency Framework" for the leadership characteristics needed for a role. Communication, managing staff by supporting and providing feedback, and emotional competence are often featured in these frameworks. It is important to distinguish between those characteristics that are learned and those that are based on traits. Learned competencies can be enhanced through personal development; innate individual differences could be acquired for a role through personnel selection (although selection based on personality is not recommended: see section 1.2). As indicated above, leadership depends on many behaviors, including matching style to situations, effective followership, and individual leadership.

A number of roles will be required in a team, and ideally these may be distributed to individuals with the apposite competencies. Emotional competence has been the focus of much recent research and some studies show a strong correlation with effective leadership (e.g. Cavallo and Brienza, 2006, who used the Emotional Competence Inventory©).

Daniel Goleman has extended and publicized the concept of emotional intelligence (an innate characteristic) and the competencies (skills that can be learned) that put it into practice. He describes how emotional aptitudes can preserve relationships, protect our health and improve our success at work (Goleman, 1998).

Goleman differentiates 5 main categories of competence. The first three are about self-management and the last two are about being effective in relationships.

1. Self-awareness: accurate self-assessment, emotional awareness and self-confidence
2. Self-regulation: innovation, adaptability, conscientiousness, trustworthiness and self-control
3. Motivation: optimism, commitment, initiative and achievement, drive
4. Empathy: developing others, service orientation, political awareness, diversity, active listening and understanding others

5. Social skills: communication, influence, conflict management, leadership, bond building, collaboration, cooperation and team capabilities

Emotional Intelligence is most associated with transformational and situational leadership.

Communication skills are also highlighted in most leader competency frameworks. These skills are about communicating to other people and listening and being communicated to by other people. Some skills are about engagement, others about sharing understanding. In particular, avoiding hidden assumptions and understanding others' perspectives are important. Communication can take place in many ways, especially with the help of IT and social media. Each mode of communication has advantages and disadvantages. Consideration should be given to how important it is to have face-to-face communication (usually better, but especially for complex matters and when emotions are involved). Although this takes more time and effort, it will often save time and effort in the long term by reducing misunderstandings and negative emotions. Nikoi (2014) presents a collection of studies that investigated the way in which communication works across media and teams.

Communication may be synchronous or asynchronous, broadcast or individual, dialogue or one-way. Bowman (2004) has a useful summary of the advantages and disadvantages of different communication channels.

Some competencies that are often associated in the literature with good leadership are listed in Table 1. The relevance of these will depend on the style and the situation/context.

Some commonly cited attributes of effective leaders are listed in Table 1 below.

Table 1. Attributes of Effective Leaders (Fairley 2009).
Reprinted with permission of the IEEE Computer Society. All other rights are reserved by the copyright owner.

Listening carefully	Maintaining enthusiasm
Delegating authority	Saying "thank you"
Facilitating teamwork	Praising team for achievements
Coordinating work activities	Accepting responsibility for shortcomings
Facilitating communication	Coaching and training
Making timely decisions	Indoctrinating newly assigned personnel
Involving appropriate stakeholders	Reconciling differences and resolving conflicts
Speaking with individual team members on a frequent basis	Helping team members develop career paths and achieve professional goals
Working effectively with the project/program manager and external stakeholders	Reassigning, transferring, and terminating personnel as necessary

Characteristics that result in effective leadership of systems engineering activities include behavioral attributes, leadership style, and communication style. In addition, a team leader for a systems engineering project or program has management responsibilities that include, but are not limited to: developing and maintaining the systems engineering plan, and establishing and overseeing the relationships between the project/program manager and project/program management personnel.

Implications for technical leadership in systems engineering

Leadership can have a significant impact on engineering performance (Kolb, 1995) and resilience (Flin, 2006). The models and styles of leadership described above emphasize the power of social skills: the ability to relate to and connect with other people. This appears to be particularly true for the sorts of situations that system engineering leaders are likely to find themselves in: working on complex problems with other professionals who are willing to follow but need to be confident in the leader's technical skill and trustworthiness. The technical leader should possess not only essential technical knowledge but should also have positive values, high levels of ethics, morality, leadership from the heart, personal capabilities, out-of-the-box thinking, interpersonal skills, etc. (Lloyd-Walker and Walker, 2011).

In a systems engineering context it is useful to recognize that different leadership functions may be distributed across a team. Some leadership functions will be knowledge focused, but it may be necessary to have a 'facilitator' (complexity) leader to ensure that the team follows the most appropriate leadership at any time. Each organization will have particular leadership requirements, which should be articulated in a behavioral framework in order to identify the most effective leadership styles and competencies, and where and how they should be applied.

Leadership capability for systems engineers should therefore be seen as a distributed capability to be developed across engineers. NASA takes a systems approach to developing leadership in their Systems Engineering Leadership Development Program (SELDP). They define technical leadership as the 'art' of systems engineering. Technical leadership includes broad technical domain knowledge, engineering instinct, problem solving, creativity, and the leadership and communication skills needed to develop new missions and systems. It focuses on systems design and technical integrity throughout the life cycle. A system's complexity and the severity of its constraints drive the need for systems engineering leadership (Williams and Reyes, 2012).

Selecting leaders by promoting the best technical performers or the most ambitious candidates is not an effective way of ensuring good leadership in an organization or program. For this reason, companies such as General Electric, Motorola, Toyota, Unilever, Raytheon, and Northrop Grumman use internal leadership academies to develop their leadership capability according to their needs (Daniels, 2009). A role model approach may be effective only if the appropriate role model is paired with a candidate, with good leadership characteristics that are valid for the situation (Yukl, 2012).

More effective approaches would involve developing competencies that can be learned through example, experience and reflection. The most effective methods will depend on the competencies needed, the type of organization, and the opportunities. They could include coaching, mentoring, shadowing, 'assistant-to' trial periods, and career management to provide experience (e.g. Fast-track).

There must also be an element of self-development: systems engineers should recognize the impact that people (or 'soft') issues have on the performance of a technical team and organization and learn how to adjust their own behavior and facilitate the behavior of others.

Behavioral Attributes

Behavioral attributes are habitual patterns of behavior, thought, and emotion that remain stable over time (Yukl 2013). Positive behavioral attributes enable a systems engineering leader to communicate effectively and to make sound decisions, while also taking into consideration the concerns of all stakeholders. Desirable behavioral attributes for a systems engineering leader include characteristics such as (Fairley 2009):

- Aptitude - This is exhibited by the ability to effectively lead a team. Leadership aptitude is not the same as knowledge or skill but rather is indicative of the ability (either intuitive or learned) to influence others. Leadership aptitude is sometimes referred to as charisma or as an engaging style.
- Initiative - This is exhibited by enthusiastically starting and following through on every leadership activity.

- Enthusiasm - This is exhibited by expressing and communicating a positive, yet realistic attitude concerning the project, product, and stakeholders.
- Communication Skills - These are exhibited by expressing concepts, thoughts, and ideas in a clear and concise manner, in oral and written forms, while interacting with colleagues, team members, managers, project stakeholders, and others.
- Team Participation - This is exhibited by working enthusiastically with team members and others when collaborating on shared work activities.
- Negotiation - This is the ability to reconcile differing points of view and achieve consensus decisions that are satisfactory to the involved stakeholders.
- Goal Orientation – This involves setting challenging but not impossible goals for oneself, team members, and teams.
- Trustworthiness - This is demonstrated over time by exhibiting ethical behavior, honesty, integrity, and dependability in taking actions and making decisions that affect others.

Weakness, on the other hand, is one example of a behavioral attribute that may limit the effectiveness of a systems engineering team leader.

Personality Traits

The concept of “personality traits” was initially introduced in the early 1900's by Carl Jung, who published a theory of personality based on three continuums: introversion-extroversion, sensing-intuiting, and thinking-feeling. According to Jung, each individual has a dominant style which includes an element from each of the three continuums. Jung also emphasized that individuals vary their personality traits in the context of different situations; however, an individual’s dominant style is the preferred one, as it is the least stressful for the individual to express and it is also the style that an individual will resort to when under stress (Jung 1971). The Myers-Briggs Type Indicator (MBTI), developed by Katherine Briggs and her daughter Isabel Myers, includes Jung’s three continuums, plus a fourth continuum of judging-perceiving. These four dimensions characterize 16 personality styles for individuals designated by letters, such as ISTP (Introverted, Sensing, Thinking, and Perceiving). An individual’s personality type indicator is determined through the answers the person has provided on a questionnaire (Myers 1995) combined with the individual’s self-assessment which is done one to one with a qualified practitioner or in a group setting. MBTI profiles are widely used by coaches and counselors to help individuals assess how their personality type will affect how they might react in a particular profession and make suggestions about which professions might suit their individual preferences. It should never be used to decide which profession would be "most comfortable and effective” as the MBTI measures preference not ability. The MBTI has also been applied to group dynamics and leadership styles. Most studies indicate that groups perform better when a mixture of personality styles work together to provide different perspectives. Some researchers claim that there is evidence that suggests that leadership styles are most closely related to an individual’s position on the judging-perceiving scale of the MBTI profile (Hammer 2001). Those on the judging side of the scale are more likely to be “by the book” managers, while those on the perceiving side of the scale are most likely to be “people-oriented” leaders. “Judging” in the MBTI model does not mean judgmental; rather, a judging preference indicates a quantitative orientation and a perceiving preference indicates a qualitative orientation. The MBTI has its detractors (Nowack 1996); however, MBTI personality styles can provide insight into effective and ineffective modes of interaction and communication among team members and team leaders. For example, an individual with a strongly Introverted, Thinking, Sensing, and Judging personality index (ITSJ) may have difficulty interacting with an individual who has a strongly Extroverted, Intuiting, Feeling, Perceiving personality index (ENFP).

Leadership Styles and Communication Styles

There is a vast amount of literature pertaining to leadership styles and there are many models of leadership. Most of these leadership models are based on some variant of Jung's psychological types. One of the models, the Wilson Social Styles, integrates leadership styles and communication styles (Wilson 2004). The Wilson model characterizes four kinds of leadership styles:

- Driver leadership style - This is exhibited when a leader focuses on the work to be accomplished and on specifying how others must do their jobs.
- Analytical-style leadership - This emphasizes collecting, analyzing, and sharing data and information. An analytical leader asks others for their opinions and recommendations to gather information.
- Amiable leadership style – This is characterized by emphasis on personal interactions and on asking others for their opinions and recommendations.
- Expressive leadership style – Like the amiable style, this also focuses on personal relationships, but an expressive leader tells others rather than asking for opinions and recommendations. When taken to extremes, each of these styles can result in weakness of leadership. By focusing too intently on the work, "drivers" can provide too much or too little guidance and direction. Too little guidance occurs when the individual is preoccupied with her or his personal work, while too much guidance results in micromanagement, which limits the personal discretion for team members. Drivers may also be insensitive to interpersonal relationships with team members and others. Analytical leaders may provide too much information or may fail to provide information that is obvious to them, but not their team members. They do not like to discuss things they already know or that are irrelevant to the task at hand. Like driver-style leaders, they may be insensitive to interpersonal relationships with other individuals. Amiable leaders focus on interpersonal relationships in order to get the job done. They may exhibit a dislike of those who fail to interact with them on a personal level and may show little concern for those who show little personal interest in them. Expressive leaders also focus on interpersonal relationships. In the extreme, an expressive leader may be more interested in stating their opinions than in listening to others. Additionally, they may play favorites and ignore those who are not favorites. While these characterizations are gross oversimplifications, they serve to illustrate leadership styles that may be exhibited by systems engineering team leaders. Effective team leaders are able to vary their leadership style to accommodate the particular context and the needs of their constituencies without going to extremes; but as emphasized by Jung, each individual has a preferred comfort zone that is least stressful and to which an individual will resort during times of added pressure.

Communication Styles

An additional characterization of the Wilson model is the preferred style of communication for different leadership styles, which is illustrated by the dimensions of assertiveness and responsiveness.

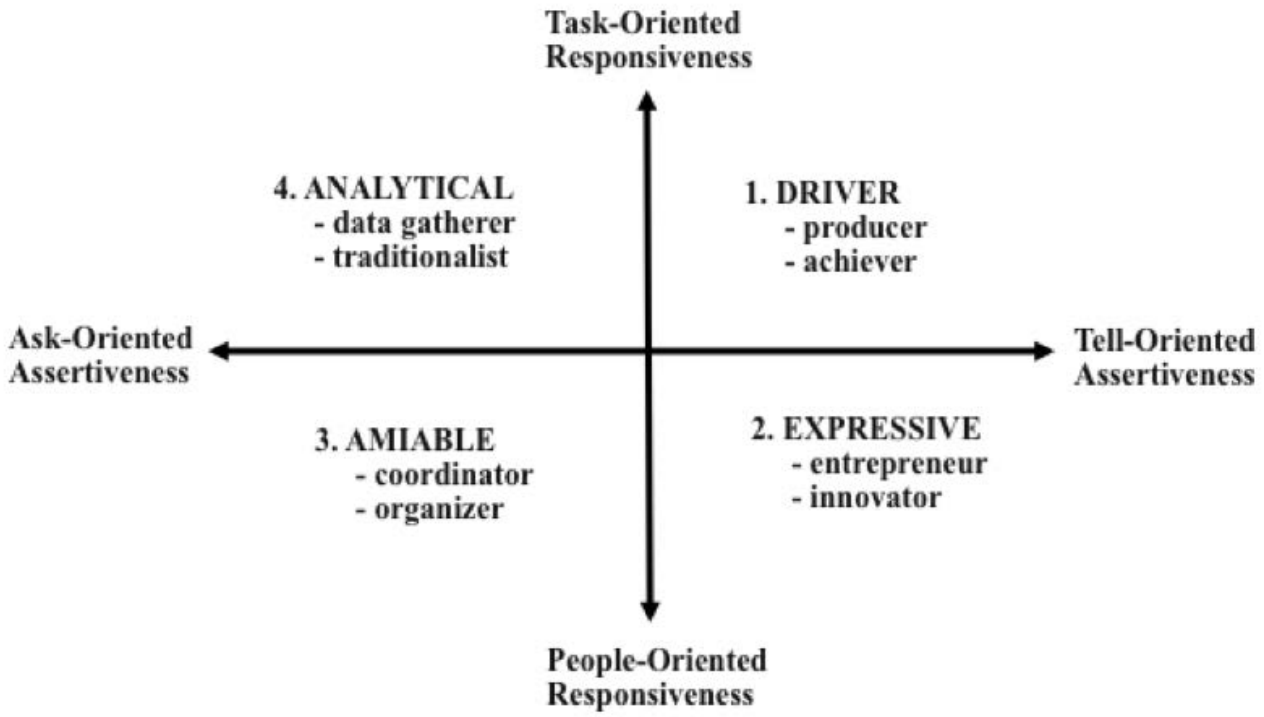

Figure 1. Dimensions of Communication Styles (Fairley 2009). Reprinted with permission of the IEEE Computer Society. All other rights are reserved by the copyright owner.

Task-oriented assertiveness is exhibited in a communication style that emphasizes the work to be done rather than the people who will do the work, while the people-oriented communication style addresses personnel issues first and tasks secondly. A tell-oriented communication style involves telling rather than asking, while an ask-oriented assertiveness emphasizes asking over telling. Movies, plays, and novels often include caricatures of extremes in the assertiveness and responsiveness dimensions of Wilson communication styles. An individual's communication style may fall anywhere within the continuums of assertiveness and responsiveness, from extremes to more moderate styles and may vary considering the situation. Examples include:

- Driver communication style exhibits task-oriented responsiveness and tell-oriented assertiveness.
- Expressive communication style shares tell-oriented assertiveness with the driver style but favors people-oriented responsiveness.
- Amiable communication style involves asking rather than telling (as does the analytical style) and emphasizes people relationships over task orientation (as does the expressive style).
- Analytical communication style exhibits task-oriented responsiveness and ask-oriented assertiveness.

The most comfortable communication occurs when individuals share the same communication styles or share adjacent quadrants in Figure 1. Difficult communication may occur when individuals are in diagonal quadrants; for example, communication between an extreme amiable style and an extreme driver style. Technical leaders and others can improve communications by being aware of different communication styles (both their own and others) and by modifying their communication style to accommodate the communication styles of others.

Management Responsibilities

Leading a systems engineering team involves communicating, coordinating, providing guidance, and maintaining progress and morale. Managing a project, according to the PMBOK® Guide (PMBOK 2013), involves application of the five process groups of project management: initiating, planning, executing, monitoring and controlling, and closing. Colloquially, systems engineering project/program management is concerned with making and updating plans and estimates, providing resources, collecting and analyzing product and process data, working with the technical leader to control work processes and work products, as well as managing the overall schedule and budget. Good engineering managers are not necessarily good technical leaders and good technical leaders are not necessarily good engineering managers; the expression of different personality traits and skill sets is required. Those who are effective as both managers and leaders have both analytical and interpersonal skills, although their comfort zone may be in one of managing or leading. Two management issues that are typically the responsibility of a systems engineering team leader are:

- Establishing and maintaining the division of responsibility among him or herself, the systems engineering team leader, and the project/program manager.
- Developing, implementing, and maintaining the systems engineering plan (SEP).

Relationships between systems engineering and project management are addressed in the Part 6 Knowledge Area (KA) of the SEBoK, Systems Engineering and Project Management. Also see the Part 5 Knowledge Area Enabling Teams for a discussion of the relationships between a project/program manager and a systems engineering technical leader.

The System Engineering Plan (SEP) is, or should be, the highest-level plan for managing the Systems Engineering effort and the technical aspects of a project or program. It defines how a project will be organized and conducted in terms of both performing and controlling the Systems Engineering activities needed to address a project's system requirements and technical content. It can have a number of secondary technical plans that provide details on specific technical areas and supporting processes, procedures, tools. Also, see the Project Planning article in Part 3, which includes a section on Systems Engineering Planning Process Overview.

In United States DoD acquisition programs, the System Engineering Plan (SEP) is a Government produced document which assists in the development, communication, and management of the overall systems engineering (SE) approach that guides all technical activities of the program. It provides direction to developers for program execution. The developer uses the SEP as guidance for producing the System Engineering Management Plan (SEMP), which is a separate document and usually a contract deliverable that aligns with the SEP. As the SEP is a Government produced and maintained document and the SEMP is a developer/contractor developed and maintained document, the SEMP is typically a standalone, coordinated document.

The following SEP outline from (ODASD 2011) serves as an example.

1. **Introduction – Purpose and Update Plan**
2. **Program Technical Requirements**
    1. Architectures and Interface Control
    2. Technical Certifications
3. **Engineering Resources and Management**
    1. Technical Schedule and Schedule Risk Assessment
    2. Engineering Resources and Cost/Schedule Reporting
    3. Engineering and Integration Risk Management
    4. Technical Organization
    5. Relationships with External Technical Organizations
    6. Technical Performance Measures and Metrics
4. **Technical Activities and Products**

1. Results of Previous Phase SE Activities
2. Planned SE Activities for the Next Phase
3. Requirements Development and Change Process
4. Technical Reviews
5. Configuration and Change Management Process
6. Design Considerations
7. Engineering Tools

5. **Annex A – Acronyms**

SEP templates are often tailored to meet the needs of individual projects or programs by adding needed elements and modifying or deleting other elements. A systems engineering team leader typically works with other team members, the project/program manager (or management team), and other stakeholders to develop the SEP and maintain currency of the plan as a project evolves. Some organizations provide one or more SEP templates and offer guidance for developing and maintaining an SEP. Some organizations have a functional group that can provide assistance in developing the SEP.

- Alice Squires and Art Pyster
-

This knowledge area focuses on enabling an individual to perform SE and addresses the roles of individuals in the SE profession, how individuals are developed for and assessed in these roles, and what ethical behavior is expected of them. Once an individual is enabled to perform SE using the techniques described here, the individual can apply the knowledge found in Part 3, Systems Engineering and Management, about how to perform SE.

Part 5, Enabling Systems Engineering, to which this knowledge area belongs, explores how systems engineering (SE) is enabled at three levels of organization: the business or enterprise, the team, and the individual. Ultimately, individuals perform SE tasks within a team or business.

For the sake of brevity, the term “business” is used to mean “business or enterprise” throughout most of this knowledge area. For a nuanced explanation of what distinguishes a business from an enterprise, see Enabling Systems Engineering.

Topics

Each part of the SEBoK is composed of knowledge areas (KAs]. Each KA groups topics together around a theme related to the overall subject of the part. This KA contains four topics:

- Roles and Competencies discusses allocation of SE roles, which sets of competencies correspond to particular roles, and what competency models are current in the SE world.
- Assessing Individuals discusses how to determine the level of individual proficiency and quality of performance.
- Developing Individuals explains how SE competency is acquired.
- Ethical Behavior describes the ethical standards that apply to individuals and organizations.

Context

The following brief review of terms and concepts provides context for the topics in this knowledge area.

Individuals, Teams, Businesses, and Enterprises

The ability to perform SE resides in individuals, teams, and businesses. An expert systems engineer possesses many competencies at a high level of proficiency, but no one can be highly proficient in all possible competencies. Collectively, a team and a business might possess all needed competencies at a high level of proficiency. A business performs the full range of SE roles, may have dedicated functions to perform specific SE roles, and may have a strategy for combining individual, team, and business abilities to execute SE on a complex activity. Individuals within the business may be responsible for performing one or more roles.

For descriptions of SE roles and competencies from the literature, see Roles and Competencies.

Competency, Capability, Capacity, and Performance

The final execution and performance of SE is a function of competency, capability, and capacity. There is some complexity here. For example:

- There is disagreement in the literature about whether the term competency applies to the individual level only, or can be correctly used at the team, project, and enterprise levels as well.
- Capability encompasses not just human capital, but processes, machines, tools, and equipment as well. Even if an individual has an outstanding level of competency, having to perform within a limited timeframe might degrade the results. Capacity accounts for this.

Systems Engineering Competency

Competency is built from knowledge, skills, abilities, and attitudes (KSAA). What is inherent in an individual may be subsequently developed through education, training, and experience. Traditionally, SE competencies have been developed primarily through experience, but recently, education and training have taken on a much greater role.

SE competency must be viewed through its relationships to the systems life cycle, the SE discipline, and the domain in which the engineer practices SE.

Competency Models

SE competency models can be used to explicitly state and actively manage the SE competencies within in an organization.

Competency models for SE typically include:

- technical KSAAs;
- “soft” KSAAs such as leadership and communications;
- KSAAs that focus on the domains within which SE is to be practiced;
- a set of applicable competencies; and
- a scale for assessing the level of individual proficiency in each competency (often subjective, since proficiency is not easily measured).

See Roles and Competencies for descriptions of publicly available SE competency models.

Roles and Competencies

- Lead Authors:
- Heidi Davidz, Dick Fairley, and Tom Hilburn
- Contributing Authors:
- Alice Squires and Art Pyster
-

Enabling individuals to perform systems engineering (SE) requires an understanding of SE competencies, roles, and tasks; plus knowledge, skills, abilities, and attitudes (KSAA). Within a business or enterprise, SE responsibilities are allocated to individuals through the definition of SE roles associated with a set of tasks. For an individual, a set of KSAAs enables the fulfillment of the competencies needed to perform the tasks associated with the assigned SE role. SE competencies reflect the individual's KSAAs, which are developed through education, training, and on-the-job experience. Traditionally, SE competencies build on innate personal qualities and have been developed primarily through experience. Recently, education and training have taken on a greater role in the development of SE competencies.

Relationship of SE Competencies and KSAAs

There are many ways to define competency. It can be thought of as a measure of the ability to use the appropriate KSAAs to successfully complete specific job-related tasks (Whitcomb, Khan, White 2014). Competencies align with the tasks that are expected to be accomplished for the job position (Holt and Perry 2011). KSAAs belong to the individual. In the process of filling a position, organizations have a specific set of competencies associated with tasks that are directly related to the job. A person possesses the KSAAs that enable them to perform the desired tasks at an acceptable level of competency.

The KSAAs are obtained and developed from a combination of several sources of learning including education, training, and on-the-job experience. By defining the KSAAs in terms of a standard taxonomy, they can be used as learning objectives for competency development (Whitcomb, Khan, White 2014). Bloom's Taxonomy for the cognitive and affective domains provides this structure (Bloom 1956, Krathwohl 2002). The cognitive domain includes knowledge, critical thinking, and the development of intellectual skills, while the affective domain describes growth in awareness, attitude, emotion, changes in interest, judgment, and the development of appreciation (Bloom 1956). The affective does not refer to additional topics which a person learns about, but rather to a transformation of the person in relation to the original set of topics learned. Cognitive and affective processes within Bloom's taxonomic classification schema refer to levels of observable actions, which indicate learning is occurring. Bloom's Taxonomy for the cognitive and affective domains define terms as categories of levels that can be used for consistently defining KSAA statements (Krathwohl 2002):

Cognitive Domain:

- Remember
- Understand
- Apply
- Analyze
- Evaluate
- Create

Affective Domain:

- Receive
- Respond
- Value
- Organize
- Characterize

Both cognitive and affective domains should be included in the development of systems engineering competency models, because the cognitive domain learning concerns the consciously developed knowledge about the various subjects and the ability to perform tasks, whilst the affective learning concerns the interest in or willingness to use particular parts of the knowledge learned and the extent to which the systems engineer is characterized by taking approaches which are inherently systemic. Using the affective domain in the specification of KSAAs, is also important as every piece of information we process in our brains goes through our affective (emotional) processors before it is integrated by our cognitive processors (Whitcomb and Whitcomb 2013).

SE Competency Models

Contexts in which individual competency models are typically used include:

- **Recruitment and Selection:** Competencies define categories for behavioral event interviewing (BEI), increasing the validity and reliability of selection and promotion decisions.
- **Human Resources Planning and Placements:** Competencies are used to identify individuals to fill specific positions and/or identify gaps in key competency areas.
- **Education, Training, and Development:** Explicit competency models let employees know which competencies are valued within their organization. Curriculum and interventions can be designed around desired competencies.

Commonality and Domain Expertise

No single individual is expected to be proficient in all the competencies found in any model. The organization, overall, must satisfy the required proficiency in sufficient quantity to support business needs. Organizational capability is not a direct summation of the competency of the individuals in the organization, since organizational dynamics play an important role that can either raise or lower overall proficiency and performance. The articles Enabling Teams and Enabling Businesses and Enterprises explore this further.

SE competency models generally agree that systems thinking, taking a holistic view of the system that includes the full life cycle, and specific knowledge of both technical and managerial SE methods are required to be a fully capable systems engineer. It is also generally accepted that an accomplished systems engineer will have expertise in at least one domain of practice. General models, while recognizing the need for domain knowledge, typically do not define the competencies or skills related to a specific domain. Most organizations tailor such models to include specific domain KSAAs and other peculiarities of their organization.

INCOSE Certification

Certification is a formal process whereby a community of knowledgeable, experienced, and skilled representatives of an organization, such as the International Council on Systems Engineering (INCOSE), provides formal recognition that a person has achieved competency in specific areas (demonstrated by education, experience, and knowledge). (INCOSE nd). The most popular credential in SE is offered by INCOSE, which requires an individual to pass a test to confirm knowledge of the field, requires experience in SE, and recommendations from those who have knowledge about the individual's capabilities and experience. Like all such credentials, the INCOSE certificate does not guarantee competence or suitability of an individual for a particular role, but is a positive indicator of an individual's ability to perform. Individual workforce needs often require additional KSAAs for any given systems engineer, but

certification provides an acknowledged common baseline.

Domain- and Industry-specific Models

No community consensus exists on a specific competency model or small set of related competency models. Many SE competency models have been developed for specific contexts or for specific organizations, and these models are useful within these contexts.

Among the domain- and industry-specific models is the Aerospace Industry Competency Model (ETA 2010), developed by the Employment and Training Administration (ETA) in collaboration with the Aerospace Industries Association (AIA) and the National Defense Industrial Association (NDIA), and available online. This model is designed to evolve along with changing skill requirements in the aerospace industry. The ETA makes numerous competency models for other industries available online (ETA 2010). The NASA Competency Management System (CMS) Dictionary is predominately a dictionary of domain-specific expertise required by the US National Aeronautics and Space Administration (NASA) to accomplish their space exploration mission (NASA 2009).

Users of models should be aware of the development method and context for the competency model they plan to use, since the primary competencies for one organization might differ from those for another organization. These models often are tailored to the specific business characteristics, including the specific product and service domain in which the organization operates. Each model typically includes a set of applicable competencies along with a scale for assessing the level of proficiency.

SE Competency Models — Examples

Though many organizations have proprietary SE competency models, published SE competency models can be used for reference. Table 1 lists information about several published SE competency models, and links to these sources are shown below in the references section. Each model was developed for a unique purpose within a specific context and validated in a particular way. It is important to understand the unique environment surrounding each competency model to determine its applicability in any new setting.

Table 1. Summary of Competency Models. (SEBoK Original)

Competency Model	Date	Author	Purpose	Development Method	Competency Model Source
INCOSE UK WG	2010	INCOSE	Identify the competencies required to conduct good systems engineering	INCOSE Working Group	(INCOSE 2010), (INCOSE UK 2010)
ENG Competency Model	2013	DAU	Identify competencies required for the DoD acquisition engineering professional	DoD and DAU internal development	(DAU 2013)
NASA APPEL Competency Model	2009	NASA	To improve project management and systems engineering at NASA	NASA internal development - UPDATE IN WORK	(NASA 2009)
MITRE Competency Model	2007	MITRE	To define new curricula for systems engineering and to assess personnel and organizational capabilities	Focus groups as described in (Trudeau 2005)	(Trudeau 2005), (MITRE 2007)
CMMI for Development	2007	SEI	Process improvement maturity model for the development of products and services	SEI Internal Development	(SEI 2007), (SEI 2004)

Other models and lists of traits include: Hall (1962), Frank (2000; 2002; 2006), Kasser et al. (2009), Squires et al. (2011), and Armstrong et al. (2011). Ferris (2010) provides a summary and evaluation of the existing frameworks for personnel evaluation and for defining SE education. Squires et al. (2010) provide a competency-based approach that can be used by universities or companies to compare their current state of SE capability development against a government-industry defined set of needs. SE competencies can also be inferred from standards such as ISO-15288

(ISO/IEC/IEEE 15288 2015) and from sources such as the INCOSE *Systems Engineering Handbook* (INCOSE 2012), the INCOSE Systems Engineering Certification Program, and CMMI criteria (SEI 2007). Whitcomb, Khan, and White describe the development of a systems engineering competency model for the United States Department of Defense based on a series of existing competency models (Whitcomb, Khan, and White 2013; 2014).

To provide specific examples for illustration, more details about three SE competency model examples follow. These include:

- The International Council on Systems Engineering (INCOSE) UK Advisory Board model (INCOSE 2010), (INCOSE UK 2009);
- The DAU ENG model (DAU 2013); and
- The NASA Academy of Program/Project & Engineering Leadership (APPEL) model (NASA 2009)

INCOSE SE Competency Model

The INCOSE model was developed by a working group in the United Kingdom (Cowper et al. 2005). As Table 2 shows, the INCOSE framework is divided into three theme areas - systems thinking, holistic life cycle view, and systems management - with a number of competencies in each. The INCOSE UK model was later adopted by the broader INCOSE organization (INCOSE 2010).

Table 2. INCOSE UK Working Group Competency (INCOSE UK 2010).

United States DoD Engineering Competency Model

The model for US Department of Defense (DoD) acquisition engineering professionals (ENG) includes 41 competency areas, as shown in Table 3 (DAU 2013). Each is grouped according to a "Unit of Competence" as listed in the left-hand column. For this model, the four top-level groupings are: analytical, technical management, professional, and business acumen. The life cycle view used in the INCOSE model is evident in the ENG analytical grouping but is not cited explicitly. Technical management is the equivalent of the INCOSE SE management, but additional competencies are added, including software engineering competencies and acquisition. Selected general professional skills have been added to meet the needs for strong leadership required of the acquisition engineering professionals. The business acumen competencies were added to meet the needs of these professionals to be able to support contract development and oversight activities and to engage with the defense industry.

	41. Negotiations

NASA SE Competency Model

The US National Aeronautics and Space Administration (NASA) APPEL website provides a competency model that covers both project engineering and systems engineering (APPEL 2009). There are three parts to the model: one that is unique to project engineering, one that is unique to systems engineering, and a third that is common to both disciplines. Table 4 below shows the SE aspects of the model. The project management items include project conceptualization, resource management, project implementation, project closeout, and program control and evaluation. The common competency areas are: NASA internal and external environments, human capital and management, security, safety and mission assurance, professional and leadership development, and knowledge management. This 2010 model is adapted from earlier versions. Squires et al. (2010, 246-260) offer a method that can be used to analyze the degree to which an organization's SE capabilities meet government-industry defined SE needs.

Table 4. SE Portion of the APPEL Competency Model (APPEL 2009). Released by NASA APPEL.

System Design	SE 1.1 - Stakeholder Expectation Definition & Management
	SE 1.2 - Technical Requirements Definition
	SE 1.3 - Logical Decomposition
	SE 1.4 - Design Solution Definition
Product Realization	SE 2.1 - Product Implementation
	SE 2.2 - Product Integration
	SE 2.3 - Product Verification
	SE 2.4 - Product Validation
	SE 2.5 - Product Transition
Technical Management	SE 3.1 - Technical Planning
	SE 3.2 - Requirements Management
	SE 3.3 - Interface Management
	SE 3.4 - Technical Risk Management
	SE 3.5 - Configuration Management
	SE 3.6 - Technical Data Management
	SE 3.7 - Technical Assessment
	SE 3.8 - Technical Decision Analysis

Relationship of SE Competencies to Other Competencies

SE is one of many engineering disciplines. A competent SE must possess KSAAs that are unique to SE, as well as many other KSAAs that are shared with other engineering and non-engineering disciplines.

One approach for a complete engineering competency model framework has multiple dimensions where each of the dimensions has unique KSAAs that are independent of the other dimensions (Wells 2008). The number of dimensions depends on the engineering organization and the range of work performed within the organization. The concept of creating independent axes for the competencies was presented in Jansma and Derro (2007), using technical knowledge (domain/discipline specific), personal behaviors, and process as the three axes. An approach that uses process as a dimension is presented in Widmann et al. (2000), where the competencies are mapped to process and process maturity models. For a large engineering organization that creates complex systems solutions, there are typically four dimensions:

1. **Discipline** (e.g., electrical, mechanical, chemical, systems, optical);
2. **Life Cycle** (e.g., requirements, design, testing);
3. **Domain** (e.g., aerospace, ships, health, transportation); and
4. **Mission** (e.g., air defense, naval warfare, rail transportation, border control, environmental protection).

These four dimensions are built on the concept defined in Jansma and Derro (2007) and Widmann et al. (2000) by separating discipline from domain and by adding mission and life cycle dimensions. Within many organizations, the mission may be consistent across the organization and this dimension would be unnecessary. A three-dimensional example is shown in Figure 1, where the organization works on only one mission area so the mission dimension has been eliminated from the framework.

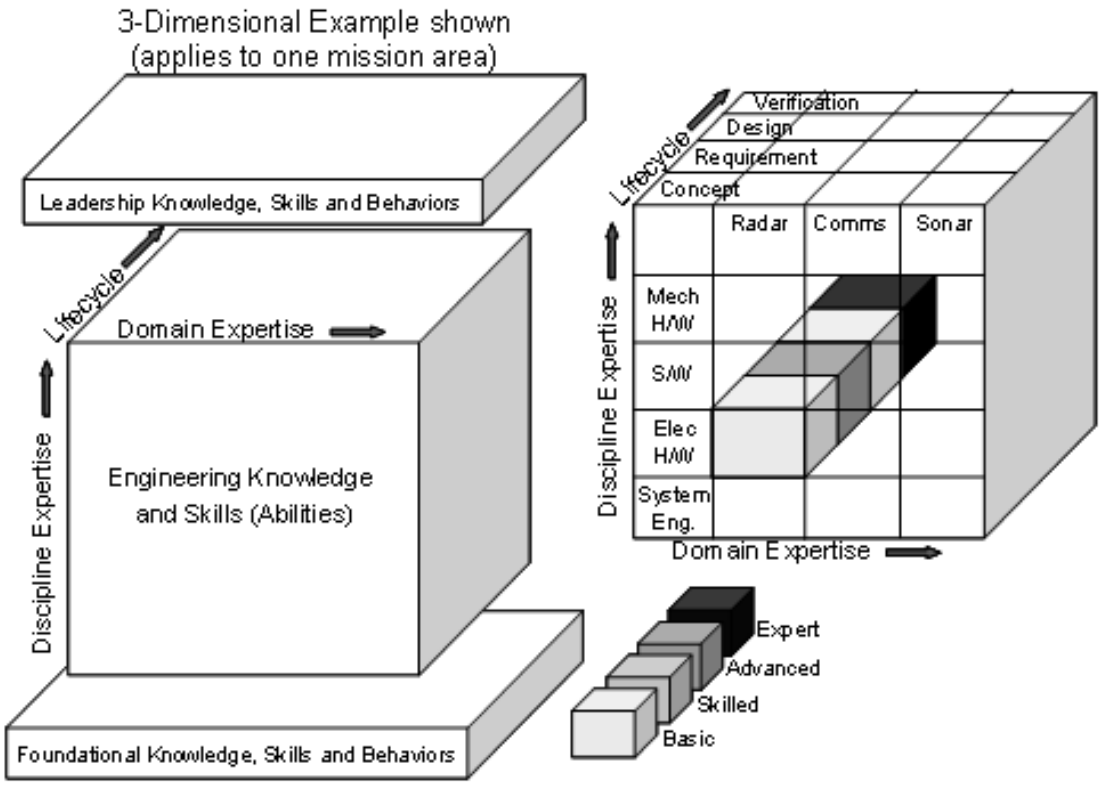

Figure 1. Layered and Multi-dimensional in the Engineering Layer (IEEE 2008). Reprinted with permission of © Copyright IEEE – All rights reserved. All other rights are reserved by the copyright owner.

The discipline, domain, and life cycle dimensions are included in this example, and some of the first-level areas in each of these dimensions are shown. At this level, an organization or an individual can indicate which areas are included in their existing or desired competencies. The sub-cubes are filled in by indicating the level of proficiency that exists or is required. For this example, blank indicates that the area is not applicable, and colors (shades of gray) are used to indicate the levels of expertise. The example shows a radar electrical designer that is an expert at hardware verification, is skilled at writing radar electrical requirements, and has some knowledge of electrical hardware concepts and detailed design. The radar electrical designer would also assess his or her proficiency in the other areas, the foundation layer, and the leadership layer to provide a complete assessment.

Assessing Individuals

- Lead Author:
- Heidi Davidz
- Contributing Authors:
- Alice Squires and Art Pyster

-

The ability to fairly assess individuals is a critical aspect of enabling individuals. This article describes how to assess the systems engineering (SE) competencies needed and possessed by an individual, as well as that individual's SE performance.

Assessing Competency Needs

If an organization wants to use its own customized competency model, an initial decision is *make vs. buy.* If there is an existing SE competency model that fits the organization's context and purpose, the organization might want to use the existing SE competency model directly. If existing models must be tailored or a new SE competency model developed, the organization should first understand its context.

Determining Context

Prior to understanding what SE competencies are needed, it is important for an organization to examine the situation in which it is embedded, including environment, history, and strategy. As Figure 1 shows, MITRE has developed a framework characterizing different levels of systems complexity. (MITRE 2007, 1-12) This framework may help an organization identify which competencies are needed. An organization working primarily in the *traditional program domain* may need to emphasize a different set of competencies than an organization working primarily in the *messy frontier.* If an organization seeks to improve existing capabilities in one area, extensive technical knowledge in that specific area might be very important. For example, if stakeholder involvement is characterized by multiple equities and distrust, rather than collaboration and concurrence, a higher level of competency in being able to balance stakeholder requirements might be needed. If the organization's desired outcome builds a fundamentally new capability, technical knowledge in a broader set of areas might be useful.

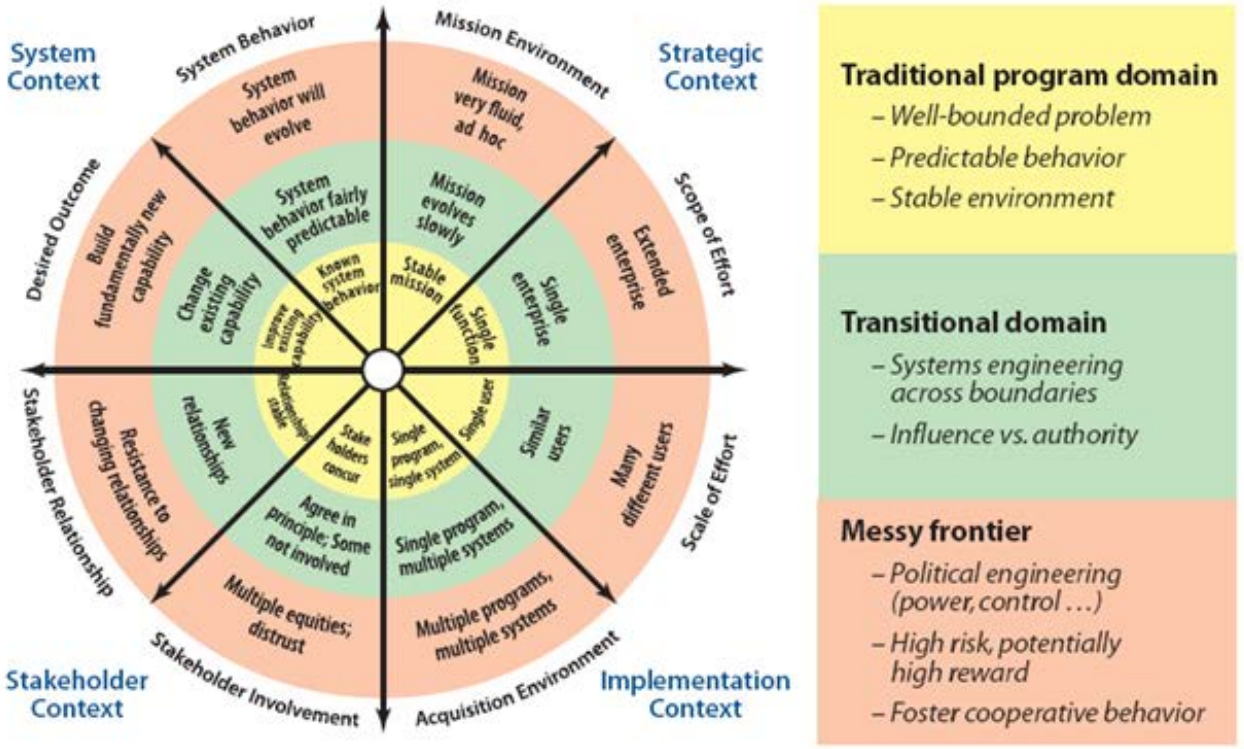

Figure 1. MITRE Enterprise Systems Engineering Framework (MITRE 2007). Reprinted with permission of © 2011. The MITRE Corporation. All Rights Reserved. All other rights are reserved by the copyright owner.

Additionally, an organization might consider both its current situation and its forward strategy. For example, if an organization has previously worked in a traditional systems engineering context (MITRE 2007) but has a strategy to transition into enterprise systems engineering (ESE) work in the future, that organization might want to develop a competency model both for what was important in the traditional SE context and for what will be required for ESE work. This would also hold true for an organization moving to a different contracting environment where competencies, such as the ability to properly tailor the SE approach to *right size* the SE effort and balance cost and risk, might be more important.

Determining Roles and Competencies

Once an organization has characterized its context, the next step is to understand exactly what SE roles are needed and how those roles will be allocated to teams and individuals. To assess the performance of an individual, it is essential to explicitly state the roles and competencies required for that individual. See the references in Roles and Competencies for guides to existing SE standards and SE competency models.

Assessing Individual SE Competency

In order to demonstrate competence, there must be some way to qualify and measure it, and this is where competency assessment is used (Holt and Perry 2011). This assessment informs the interventions needed to further develop individual SE KSAA upon which competency is based. Described below are possible methods which may be used for assessing an individual's current competency level; an organization should choose the correct model based on their context, as identified previously.

Proficiency Levels

In order to provide a context for individuals and organizations to develop competencies, a consistent system of defining KSAAs should be created. One popular method is based on Bloom's taxonomy (Bloom 1984), presented below for the cognitive domain in order from least complex to most complex cognitive ability.

- **Remember**: Recall or recognize terms, definitions, facts, ideas, materials, patterns, sequences, methods, principles, etc.
- **Understand**: Read and understand descriptions, communications, reports, tables, diagrams, directions, regulations, etc.
- **Apply**: Know when and how to use ideas, procedures, methods, formulas, principles, theories, etc.
- **Analyze**: Break down information into its constituent parts and recognize their relationships to one another and how they are organized; identify sublevel factors or salient data from a complex scenario.
- **Evaluate**: Make judgments about the value of proposed ideas, solutions, etc., by comparing the proposal to specific criteria or standards.
- **Create**: Put parts or elements together in such a way as to reveal a pattern or structure not clearly there before; identify which data or information from a complex set is appropriate to examine further or from which supported conclusions can be drawn.

One way to assess competency is to assign KSAAs to proficiency level categories within each competency. Examples of proficiency levels include the INCOSE competency model, with proficiency levels of: awareness, supervised practitioner, practitioner, and expert (INCOSE 2010). The Academy of Program/Project & Engineering Leadership (APPEL) competency model includes the levels: participate, apply, manage, and guide, respectively (Menrad and Lawson 2008). The U.S. National Aeronautics and Space Administration (NASA), as part of the APPEL (APPEL 2009), has also defined proficiency levels: technical engineer/project team member, subsystem lead/manager, project manager/project systems engineer, and program manager/program systems engineer. The Defense Civilian Personnel Advisory Service (DCPAS) defines a 5-tier framework to indicate the degree to which employees perform compentencies as awareness, basic, intermediate, advanced, and expert.

The KSAAs defined in the lower levels of the cognitive domain (remember, understand) are typically foundational, and involve demonstration of basic knowledge. The higher levels (apply, analyze, evaluate, and create) reflect higher cognitive ability. Cognitive and affective processes within Bloom's taxonomy refer to levels of observable actions that indicate learning is occuring (Whitcomb et al. 2015). The Bloom's domain levels should not be used exclusively to determine the proficiency levels required for attainment or assessment of a competency. Higher level cognitive capabilities belong across proficiency levels, and should be used as appropriate to the KSAA involved. These higher-level terms infer some observable action or outcome, so the context for assessing the attainment of the KSAA, or a group of KSAAs, related to a competency needs to be defined. For example, applying SE methods can be accomplished on simple subsystems or systems and so perhaps belong in a lower proficiency level such as supervised practitioner. Applying SE methods to complex enterprise or systems of systems, may belong in the practitioner or even the expert level. The determination of what proficiency level is desired for each KSAA is determined by the organization and may vary among different organizations.

Quality of Competency Assessment

When using application as a measure of competency, it is important to have a measure of *goodness*. If someone is applying a competency in an exceptionally complex situation, they may not necessarily be successful in this application. An individual may be *managing and guiding*, but this is only helpful to the organization if it is being done well. In addition, an individual might be fully proficient in a particular competency, but not be given an opportunity to use that competency; for this reason, it is important to understand the context in which these competencies are being assessed.

Individual SE Competency versus Performance

Even when an individual is highly proficient in an SE competency, context may preclude exemplary performance of that competency. For example, an individual with high competency in risk management may be embedded in a team or an organization which ignores that talent, whether because of flawed procedures or some other reason. Developing individual competencies is not enough to ensure exemplary SE performance.

When SE roles are clearly defined, performance assessment at least has a chance to be objective. However, since teams are most often tasked with accomplishing the SE tasks on a project, it is the team's performance which ends up being assessed. (See Team Capability). The final execution and performance of SE is a function of competency, capability, and capacity. (See Enabling Teams and Enabling Businesses and Enterprises.)

Developing Individuals

- Lead Author:
- Heidi Davidz

-

Developing each individual's systems engineering (SE) competencies is a key aspect of enabling individuals. The goal may be to develop competency in a broad range of SE competencies or a single aspect of SE, and it is important to know exactly which SE competencies are desired. This article describes strategies to develop SE competencies in individuals.

Closing Competency Gaps

Delivering excellent systems that fulfill customer needs is the primary goal of the organization. Developing the ''capability *to deliver such systems is a secondary goal, and while necessary, is not sufficient. To attain both of these goals, the organization must assess itself and effect a strategy to identify and close competency gaps.*

To identify competency gaps, an organization may take two basic steps:

1. Listing desired competencies, as discussed in Roles and Competencies; and
2. Assessing the competencies of individual systems engineers, as discussed in Assessing Individuals.

Models useful for listing competencies include the International Council on Systems Engineering (INCOSE) United Kingdom Advisory Board model (Cowper et al. 2005; INCOSE 2010), the ENG Competency Model (DAU 2013), and the Academy of Program/Project & Engineering Leadership (APPEL 2009) model (Menrad and Lawson 2008).

Once the organization knows the SE competencies it needs to develop to close the competency gaps it has identified, it may choose from the several methods (Davidz and Martin 2011) outlined in the table below.

Table 1. SE Competency Development Framework. (SEBoK Original)

Goal	Objective	Method
PRIMARY GOAL = Delivery of excellent systems to fulfill customer needs	Focus on successful performance outcome	Corporate intiatives
	Focus on performance of project team	Team coaching of project team for performance enhancement
SECONDARY GOAL = Competency to deliver excellent systems to fulfill customer needs	Develop individual competency	Training courses
		Job rotation
		Mentoring
		Hands-on experience
		Develop a few hand-picked individuals
		University educational degree program
		Customized educational program
		Combination program - education, training, job rotation, mentoring, hands-on experience
		Course certificate program

	Ensure individual competency through certification	Certification program
	Filter those working in systems roles	Use individual characteristics to select employees for systems roles
	Ensure organizational competency through certification	ISO 9000
	Develop organizational systems competency through processes	Process improvement using an established framework
		Concept maps to identify the thought processes of senior systems engineers
		Standarize systems policies and procedures for consistency
		Systems engineering web portal
		Systems knowledge management repository
		On-call organizational experts
		Rotating professor who works at company part-time and is at university part-time

System Delivery

Some organizations mount initiatives which focus directly on successful system delivery. Others focus on project team performance, in some cases by offering coaching, as a means to ensure successful system delivery.

One example of the latter approach is the performance enhancement service of the US National Aeronautics and Space Administration (NASA) Academy of Program/Project & Engineering Leadership (APPEL), which assesses team performance and then offers developmental interventions with coaching (NASA 2010).

Organizations pursue multiple paths towards developing the capability to deliver excellent systems, including:

- developing the competency of individuals;
- developing the competency of the organization through processes (Davidz and Maier 2007); and
- putting measures in place to verify the efficacy of the selected methods.

Individual Competency

An organization may choose a combination of methods to develop individual systems competency. General Electric's Edison Engineering Development Program (GE 2010) and Lockheed Martin's Leadership Development Programs (Lockheed Martin 2010) are examples among the many combination programs offered within companies.

Whether or not the program is specifically oriented to develop systems skills, the breadth of technical training and experience, coupled with business training, can produce a rich understanding of systems for the participant. Furthermore, new combination programs can be designed to develop specific systems-oriented skills for an organization.

Methods for developing individual competency include:

- **classroom or online training courses**, a traditional choice for knowledge transfer and skill acquisition. Here, an instructor directs a classroom of participants. The method of instruction may vary from a lecture format to case study work to hands-on exercises. The impact and effectiveness of this method varies considerably based on the skill of the instructor, the effort of the participants, the presentation of the material, the course content, the quality of the course design process, and the matching of the course material to organizational needs. These types of interventions may also be given online. Squires (2011) investigates the relationship between online pedagogy and

student perceived learning of SE competencies.

- **job rotation**, where a participant rotates through a series of work assignments that cut across different aspects of the organization to gain broad experience in a relatively short time.
- **mentoring**, where a more experienced individual is paired with a protégé in a developmental relationship. Many organizations use mentoring, whose impact and effectiveness vary considerably. Success factors are the tenable pairing of individuals, and the provision of adequate time for mentoring.
- **hands-on experience**, where organizations provide for their engineers to get hands-on experience that they would otherwise lack. A research study by Davidz on enablers and barriers to the development of systems thinking showed that systems thinking is developed primarily by experiential learning (Davidz 2006; Davidz and Nightingale 2008, 1-14). As an example, some individuals found that working in a job that dealt with the full system, such as working in an integration and test environment, enabled development of systems thinking.
- **selecting individuals** who appear to have high potential and focusing on their development. Hand-selection may or may not be accompanied by the other identified methods.
- **formal education**, such as a university degree program. A growing number of SE degree programs are offered worldwide (Lasfer and Pyster 2011). Companies have also worked with local universities to set up customized educational programs for their employees. The company benefits because it can tailor the educational program to the unique needs of its business. In a certificate program, individuals receive a certificate for taking a specific set of courses, either at a university or as provided by the company. There are a growing number of certificate programs for developing systems competency.

Individual Certification

Organizations may seek to boost individual systems competency through certification programs. These can combine work experience, educational background, and training classes. Certifications are offered by local, national, and international professional bodies.

SE organizations may encourage employees to seek certification from the International Council on Systems Engineering (INCOSE 2011) or may use this type of certification as a filter (see **Filters**, below). In addition, many companies have developed their own internal certification measures. For example, the Aerospace Corporation has an Aerospace Systems Architecting and Engineering Certificate Program (ASAECP). (Gardner 2007.)

Filters

Another approach to developing individual competency is to select employees for systems roles based on certain characteristics, or filters. Before using a list of characteristics for filtering, an organization should critically examine:

1. how the list of individual characteristics was determined, and
2. how the characteristics identified enable the performance of a systems job.

Characteristics used as filters should:

- enable one to perform a systems job,
- be viewed as important to perform a systems job, or
- be necessary to perform a systems job.

A necessary characteristic is much stronger than an enabling one, and before filtering for certain traits, it is important to understand whether the characteristic is an enabler or a necessity.

Finally, it is important to understand the extent to which findings are generally applicable, since a list of characteristics that determine success in one organization may not be generalizable to another organization.

Organizational Capability

Once an organization has determined which SE capabilities are mission critical (see Deciding on Desired Systems Engineering Capabilities within Businesses and Enterprises), there are many different ways in which an organization can seek to develop or improve these capabilities. Some approaches seen in the literature include the following:

- Organizations may choose to develop organizational systems capability through processes. One method organizations may choose is to pursue process improvement using an established framework. An example is the Capability Maturity Model® Integration (CMMI) process improvement approach (SEI 2010, 1).
- Concept maps - graphical representations of engineering thought processes - have been shown to be an effective method of transferring knowledge from senior engineering personnel to junior engineering personnel (Kramer 2007, 26-29; Kramer 2005). These maps may provide a mechanism for increasing knowledge of the systems engineering population of an organization.
- An organization may also choose to develop organizational systems competencies by standardizing systems policies and procedures. An example from NASA is their *NASA Systems Engineering Processes and Requirements* (NASA 2007).
- Some organizations use a web portal to store and organize applicable systems engineering knowledge and processes, which assists in developing organizational systems competency. An example is the Mission Assurance Portal for the Aerospace Corporation (Roberts et al. 2007, 10-13).
- Another approach being considered in the community is the development of a rotating professor role, where the person would work at the company and then at a university to strengthen the link between academia and industry.
- Another approach is to alter organizational design to foster and mature a desired competency. For example, an organization that identifies competency in the area of reliability as critical to its SE success may develop a reliability group, which will help foster growth and improvement in reliability competencies.

Organizational Certification

Certification at the organizational level also exists and can be a means for ensuring competency. ISO certification is one example (ISO 2010). Before taking this approach, the organization should verify that the capabilities required by the certification are indeed the systems capabilities it seeks. For more on determining appropriate organizational capabilities, see Deciding on Desired Systems Engineering Capabilities within Businesses and Enterprises.

Repositioning the Product Life Cycle

An organization may also choose to reposition its product life cycle philosophy to maintain system competency. For example, NASA has done this with its APPEL program (APPEL 2009).

Since the systems competencies of individuals are primarily developed through experiential learning, providing experiential learning opportunities is critical. Shortening the product life cycle is one way to ensure that individuals acquire the full range of desired competency sooner.

Maintaining Competency Plans

An organization that has developed an SE competency plan should consider how to maintain it. How, and how often, will the competency plan be re-examined and updated? The maintenance process should account for the ongoing evolution of global contexts, business strategies, and the SEBoK. The process for assessing competencies and taking action to improve them must be part of the normal operations of the organization and should occur periodically.

Ethical Behavior

- Lead Authors:
- Dick Fairley and Chuck Calvano
- Contributing Authors:
- Scott Jackson, Heidi Davidz, Alice Squires, and Art Pyster

-

If the competency of the systems engineer is a matter of KSAA—knowledge, skills, abilities, and attitudes—then the word “attitudes” must have an ethical dimension. The ethical framework that guides the SE's actions ensures that the SE ultimately does good and not harm. Ethical standards apply both to individuals and to organizations. This section discusses the moral foundations of ethics, and the elements of ethical conduct that are especially relevant to systems engineering.

Ethics and Morals in Systems Engineering

Like other people, systems engineers have morals: guiding personal thoughts and feelings about what is right and wrong. All of us also share, with other members of various communities to which we belong, ethics: standards that say what conduct is appropriate and what is not (Whitbeck 2007).

Morals are part of a person's character, the result of upbringing, culture, and other environmental influences. **Ethics** apply morals within the frame of a social system, which could be professional, business, academic, recreational, cultural, political, religious, or even familial. While a person’s moral code is usually considered immutable, one's ethics may need to account for new situations as one's profession or role in life changes. Tensions may exist between an engineer's responsibilities to society and those to the customer, the employer, or even the family, resulting in ethical dilemmas, and creating situations where morals come into play.

There is no shortage of discussion on ethics. Ethical codes are promulgated by professional and other organizations. **Professions** here refers to occupations that require learning and advanced knowledge and which safeguard or promote the well-being of others and of society as a whole.

Systems engineers have two ethical responsibilities over and above those of most other engineering professions:

- While engineers in general use their professional skills to address customer needs and desires, systems engineering (SE) helps *determine* those needs and desires in the course of defining and managing requirements. SEs have an obligation to ensure that problem or program definition is influenced solely by the interests of the customer or user, not by those of the systems engineer or the engineer’s firm.
- Systems engineers typically integrate and oversee the work of others whose expertise differs from their own. This makes the obligation to widen one’s understanding and to seek competent advice from other professionals more acute in SE than in other disciplines.

Caroline Whitbeck's *Ethics in Engineering Practice and Research* explains what ethical behavior means for engineering professionals. Like most books on ethics, this one starts by clarifying the differences between ethics and morals, which can seem somewhat obscure at times (Whitbeck 2007).

A sampling of areas where ethics figure in the engineering of modern systems are described below.

Data Confidentiality and Security, Surveillance, and Privacy

Privacy, confidentiality, and security in systems which touch Personally Identifiable Information (PII) have an ethical dimension for the systems engineers responsible for developing those systems.

Laws and Regulations

Systems are typically developed in societies, sometimes involving international communities, which have laws concerning contracts, intellectual property, freedom of information, and employment. The requirements and restraints of those laws govern the practice of the systems engineer, who must be aware of the laws and must consider their implications for the partnerships that system development entails.

Whether or not they are stated in the system requirements document or provided by the customer, laws and regulations do, in fact, impose system requirements. SEs are responsible for knowing and applying relevant laws and regulations. This means recognizing other people's proprietary interests by safeguarding their intellectual property (trade secrets, copyrights, trademarks, and patents), and giving them credit for performing work and making innovations.

Cultural Issues

Since systems engineers develop and maintain products used by humans globally, it is important that they understand the historical and cultural aspects of their profession and the related context in which their products will be used. System engineers need to be aware of societal diversity and act without prejudice or discrimination.

Ethical Considerations in the Systems Engineering Method

Naturally, SE approaches to meeting customer needs must integrate SE ethics.

Codes of Ethics and Professional Conduct

Codes of ethics are promulgated by the IEEE (IEEE 2009), the National Society of Professional Engineers (NSPE) (NSPE 2007), the International Council on Systems Engineering (INCOSE 2006) and other engineering organizations.

The INCOSE Code of Ethics enunciates fundamental ethical principles like honesty, impartiality, integrity, keeping abreast of knowledge, striving to increase competence, and supporting educational and professional organizations. Based on these principles, the code identifies the systems engineer's fundamental duties to society and the public, and the rules of practice that systems engineers should follow to fulfill those duties.

According to the INCOSE Code of Ethics, it is the systems engineer's duty to:

- guard the public interest and protect the environment, safety, and welfare of those affected by engineering activities and technological artifacts;
- accept responsibility for one's actions and engineering results, including being open to ethical scrutiny and assessment;
- proactively mitigate unsafe practice;
- manage risk using knowledge gained by applying a whole-system viewpoint and understanding of systemic interfaces; and
- promote the understanding, implementation, and acceptance of prudent SE measures.

Enforcing Ethics

Many organizations enforce ethics internally by means of ethics policies. These polices typically include rules such as the following:

- There shall be no exchange of favors between anyone in the organization and entities with which it does business, such as suppliers, customers, or regulatory agencies.
- Product information, for example, test data, shall be reported accurately and completely to the contracting agency.
- There shall be no conflict of interest between the organization and entities with which it does business.

Favors can consist of providing money, reimbursement of travel or entertainment expenses, other items of equivalent value, or inappropriate job offers. Conflict of interest can arise when the personal or professional financial interests or organizational ties of an engineer are potentially at odds with the best interests of the customer or the engineer's employer. Since conflict of interest and other ethical transgressions can be hard to define, care must be taken to design ethics policies that are observable and enforceable. Internal audit functions or external regulatory agencies may enforce ethical rules at the individual, team, organizational, or enterprise level. Punishment for violating ethics policies can include termination and other disciplinary actions.

Unlike self-employed physicians who may choose to not do something specific, many systems engineers are individuals employed by organizations. Depending on the organizational context, an issue in conflict with the company might result in giving up the job. This may result in additional ethical considerations.

Responsibility to Society

Engineers who create products and services for use in society have an obligation to serve the public good. Additionally, the IEEE Code of Ethics states that engineers have an obligation to foster the professional development and ethical integrity of colleagues (IEEE 2015). Because of the criticality and scope of many systems, systems engineers, operating in teams within projects and on behalf of the public in delivery of products, have special responsibility. Poorly designed systems or services can have calamitous effects on society. The INCOSE Code of Ethics asserts the responsibility of systems engineers to "guard the public interest and protect the environment, safety, and welfare of those affected by engineering activities and technological artifacts" (INCOSE 2006).

-

One of the most fundamental tenets of systems engineering (SE) is that of approaching systems from an integrated, holistic perspective (INCOSE 2023), with an eye towards how sets of interconnected components and their surrounding environments interface and interact with each other to shape the nature, characteristics, and dynamics of systems of interest (SoIs). In a similar fashion, it is possible to regard systems engineering itself as a system, which interacts and intersects with adjoining and related disciplines, communities of practice, and areas of study. These related fields form the systems context in which the field of systems engineering exists, and play a critical role in not only facilitating the effective use of systems engineering in various application areas, but also in shaping the current nature and future evolution of systems engineering as drivers of the overall operational environment in which systems engineering exists (Singam 2022a). Part 6 of the (SEBoK) provides the reader with an overview of many of these related disciplines, discussion on how these disciplines help enrich and enliven systems engineering, and vice versa.

Context

Systems engineering (SE) is a fundamentally transdisciplinary endeavor (INCOSE 2019): its principles and practices are sufficiently abstract and generic as to be readily applicable to any system, regardless of application area or associated discipline(s) relevant to the system of interest (Kossiakoff et al. 2011). The flexibility and versatility of the SE toolkit is part of what makes it such a valuable asset on projects, especially those involving large or complex systems which require the integration of various disparate elements and technical disciplines into a single, unified system (INCOSE 2023, Elm et. al. 2008). In order to realize that versatility, though, SE practitioners need to have a wide range of technical knowledge that extends beyond that of "pure" SE and across the various disciplines relative to the system(s) of interest. A systems engineer who has responsibility for overseeing the interface between a mechanical subsystem and an electrical subsystem in a biomedical device, for instance, would at minimum need knowledge of mechanical engineering and electrical engineering *topics* in order to perform a systems engineering task such as setting interface requirements. However, in the context of a biomedical device for human use,

familiarity with concepts in biology, safety engineering, electromagnetic interference, human-systems integration, and law/policy - just to name a few - are likely to also become relevant in order for the systems engineer to appropriately communicate and integrate information from across the project, as well as ensure that the interface is fit-for-purpose and within acceptable parameters. It thus behooves the well-prepared systems engineer to maintain familiarity with a broad selection of related disciplines.

Purpose and Scope

Part 6 of the SEBoK intends to aid systems practitioners and other individuals with an interest in SE in augmenting their technical knowledge of subjects relevant to systems engineering practice, and providing a foundation for independent exploration of associated topics via relevant resources.

Part 6's purview encompasses the many fields and topics which enrich the discipline of SE, inclusive of both commonly-discussed disciplines such as those classified under the science, technology, engineering, and mathematics (STEM) quartet, as well as oft-overlooked disciplines of relevance in the arts and humanities. Part 6 is therefore arguably the most expansive section of the SEBoK in terms of potential scope, as it extends beyond the boundaries of formal SE and SE application areas, and across the breadth of academic and practical knowledge. Even so, the disciplines discussed in this section are only a subset of the full expanse of those which relate to systems engineering: it is, after all, neigh impossible to find a topic or discipline which does not involve or reckon with system(s), and thus systems engineering, in some way (Singam 2022b). Consequently, rather than attempting a full census of the adjacent or related knowledge areas (KAs) that abut the edges of formal systems engineering, Part 6 instead seeks to proffer a curated smörgåsbord of the many related disciplines which bear relevance to systems engineering, with a focus on KAs that are most likely to be of relevance to a diverse, multi-disciplinary audience of systems-minded professionals, learners, and educators.

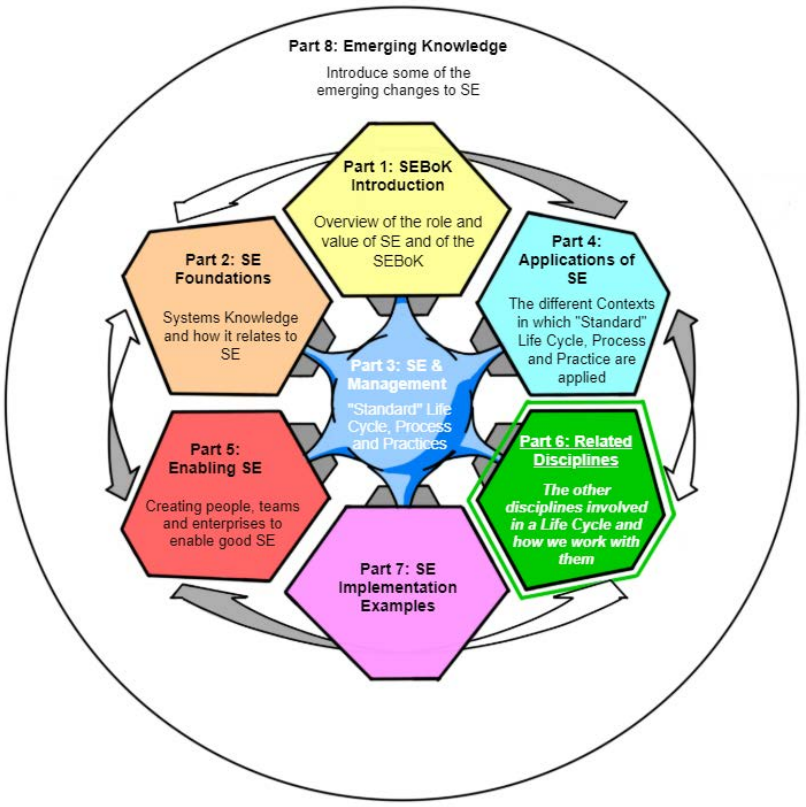

Figure 1. SEBoK Part 6 in context (SEBoK Original). For further details, see Structure of the SEBoK.

Knowledge Areas in Part 6

The KAs covered in Part 6 are all distinct areas of study or practice (i.e., disciplines which are commonly recognized as separate from systems engineering) that meet one or more of the following descriptors:

1. disciplines which are independent from, but overlap with, formal SE practice and/or the core SE body of knowledge (e.g., project management);
2. specialized disciplines focused on in-depth exploration of specific topics that abut or extend beyond the scope of the core/non-specialist SE body of knowledge (e.g., quality engineering);
3. specialist disciplines which are commonly used to describe or govern the characteristics, dynamics, or life cycle of the composite elements of interdisciplinary or multi-disciplinary systems (e.g., physics, biology, mechanical engineering, software engineering, etc.);
4. disciplines which are frequently relevant to the effective and/or ethical practice of SE in a commonly encountered system context (e.g., environmental engineering, information technology (IT) for enterprise systems, law);
5. specialized disciplines which frequently utilize systems engineering methodologies or have a substantial systems engineering/systems science community of practice (e.g., geospatial engineering), and which can provide new generalizable insights into the improvement and evolution of systems engineering as a field;
6. other specialized disciplines which are of substantial interest in non-specialist contexts.

Current Content

At present, Part 6 is organized into the following sub-sections, each representing a key KA:

- Systems Engineering and Environmental Engineering
- Systems Engineering and Geospatial/Geodetic Engineering
- Systems Engineering and Industrial Engineering
- Systems Engineering and Project Management
  - *Other sub-topics*: project structure and governance; procurement and acquisition; portfolio management
- Systems Engineering and Software Engineering
- Systems Engineering and Mechanical Engineering
- Systems Engineering and Enterprise IT
- Systems Engineering and Quality Attributes (This encompasses quality engineering, but is also the home of the disciplines focused on characteristics of systems, sometimes referred to as "-ilities".)
  - *Other subtopics*: human-systems integration (HSI); manufacturability and producibility; adaptability; affordability; hardware assurance; reliability/availability/maintainability; resilience; resistance to electromagnetic interference; safety; security

As reflected by the sub-section titles within Part 6 ("Systems Engineering and...."), each main KA is focused on the intersection between systems engineering and a given topic, and contains at least one article discussing aspects of that KA that would be of import to a systems engineer from outside that particular specialty. Some of the broader KAs, such as those on project management and quality attributes, also include articles on KA-relevant sub-topics alongside the KA overview articles, as per the categorization listed above.

Future Content

Astute readers may note that pre-existing content in Part 6 is almost exclusively focused on areas of specialist engineering; as Part 6's content continues to evolve, it is planned that the KAs covered in this section will be updated to better reflect the current range of SE-adjacent knowledge and practice across across various related disciplines, in accordance with broadened interest from both academia and industry (Han et. al. 2023) in exploring interdisciplinary and cross-disciplinary KAs. In particular, it is planned that future versions of Part 6 will include content on related disciplines that are often overlooked in overviews of SE-relevant subject matter, such as topics in the arts and humanities.

Knowledge Area: Systems Engineering and Environmental Engineering

Systems Engineering and Environmental Engineering

- Lead Authors:
- Paul Phister and David Olwell

-

Environmental engineering addresses four issues that arise in system design and operation. They are: (1) design for a given operating environment, (2) environmental impact, (3) green design, and (4) compliance with environmental regulations.

Overview

A system is designed for a particular operating environment. Product systems, in particular, routinely consider conditions of temperature and humidity. Depending on the product, other environmental conditions may need to be considered, including UV exposure, radiation, magnetic forces, vibration, and others. The allowable range of these conditions must be specified in the requirements for the system.

Requirements

The general principles for writing requirements also apply to specifying the operating environment for a system and its elements. Requirements are often written to require compliance with a set of standards.

Discipline Management

Many countries require assessment of environmental impact of large projects before regulatory approval is given. The assessment is documented in an environmental impact statement (EIS). In the United States, a complex project can require an EIS that greatly adds to the cost, schedule, and risk of the project.

Scope

In the U.S., the process in Figure 1 is followed. A proposal is prepared prior to a project being funded. The regulator examines the proposal. If it falls into an excluded category, no further action is taken. If not, an environmental assessment is made. If that assessment determines a finding of no significant impact (FONSI), no further action is taken. In all other cases, an environmental impact statement is required.

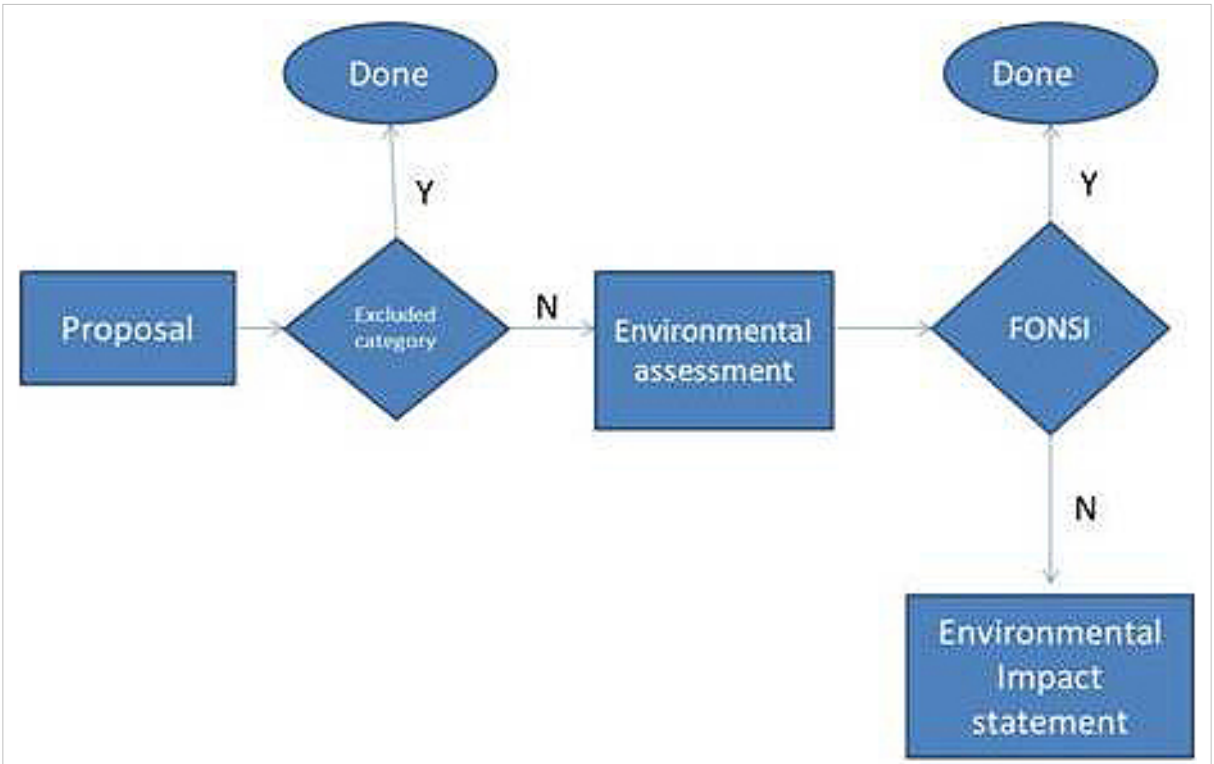

Figure 1. Flowchart to Decide if an EIS is Necessary. (SEBoK Original)

Preparation of an EIS is a resource significant task. Bregman (2000) and Kreske (1996) provide accessible overviews of the process. Lee and Lin (2000) provide a handbook of environmental engineering calculations to aid in the technical submission. Numerous firms offer consulting services.

Legal References

Basic references in the U.S. include the National Environmental Policy Act of 1969 and its implementing regulations (NEPA 1969) and the European Ccommission directive (EC 1985). State and local regulations can be extensive; Burby and Paterson (1993) discuss improving compliance.

Cost and Schedule Implications

Depending on the scale of the project, the preparation of an EIS can take years and cost millions. For example, the EIS for the Honolulu light rail project took four years and cost $156M (Hill 2011). While a project may proceed even if the EIS finds a negative impact, opponents to a project may use the EIS process to delay a project. A common tactic is to claim the EIS was not complete in that it omitted some environmental impacts. Eccleston (2000) provides a guide to planning for EIS.

Energy Efficiency

There is a large amount of literature that has been published about design for energy efficiency. Lovins (2010) offers ten design principles. He also provides case studies (Lovins et al. 2011). Intel (2021) provides guidance for improving the energy efficiency of its computer chips. A great deal of information is also available in regard to the efficient design of structures; DOE (2011) provides a good overview.

Increased energy efficiency can significantly reduce total life cycle cost for a system. For example, the Toyota Prius was found to have the lowest life cycle cost for 60,000 miles, three years despite having a higher initial purchase price (Brown 2011).

Carbon Footprint

Increased attention is being paid to the emission of carbon dioxide. BSI British Standards offers a specification for assessing life cycle greenhouse emissions for goods and services (BSI 2011).

Sustainability

Graedel and Allenby (2009), Maydl (2004), Stasinopoulos (2009), Meryman (2004), and Lockton and Harrison (2008) discuss design for sustainability. Sustainability is often discussed in the context of the UN report on Our Common Future (WCED 1987) and the Rio Declaration (UN 1992).

Discipline Relationships

An enterprise must attend to compliance with the various environmental regulations. Dechant et al. (1994) provide the example of a company in which 17% of every sales dollar goes toward compliance activities. They discuss gaining a competitive advantage through better compliance. Gupta (1995) studies how compliance can improve the operations function. Berry (1998) and Nash (2001) discuss methods for environmental management by the enterprise.

Dependencies

ISO14001 sets the standards for organization to comply with environmental regulations. Kwon and Seo (2002) discuss this in a Korean context, and Whitelaw (2004) presents a handbook on implementing ISO14001.

Discipline Standards

Depending on the product being developed, standards may exist for operating conditions. For example, ISO 9241-6 specifies the office environment for a video display terminal. Military equipment may be required to meet MILSTD 810G standard (DoD 2014) in the US, or DEF STAN 00-35 in the UK (MoD 2017).

The U.S. Federal Aviation Administration publishes a list of EIS best practices (FAA 2002).

The U.S. Environmental Protection Agency (EPA) defines green engineering as: the design, commercialization, and use of processes and products, which are feasible and economical, while minimizing (1) generation of pollution at the source and (2) risk to human health and the environment (EPA 2011). Green engineering embraces the concept that decisions to protect human health and the environment can have the greatest impact and cost effectiveness when applied early to the design and development phase of a process or product.

The EPA (2011) offers the following principles of green engineering:

- Engineer processes and products holistically, use systems analysis, and integrate environmental impact assessment tools.
- Conserve and improve natural ecosystems while protecting human health and well-being.
- Use life-cycle thinking in all engineering activities.

- Ensure that all material and energy inputs and outputs are as inherently safe and benign as possible.
- Minimize depletion of natural resources.
- Strive to prevent waste.
- Develop and apply engineering solutions, while being cognizant of local geography, aspirations, and cultures.
- Create engineering solutions beyond current or dominant technologies; additionally, improve, innovate, and invent (technologies) to achieve sustainability.
- Actively engage communities and stakeholders in development of engineering solutions.

Geographic Information Systems (GIS) and geospatial applications and infrastructures are widely used and widely integrated into other systems. Among the most well-known such systems are those based on the Global Positioning System (GPS) and other Global Navigation Satellite Systems (GNSS). They have enabled such diverse applications as automobile navigation systems, smartphones that location-stamp photographs, and military weapon systems that target enemy locations. Where it is often claimed that 80% of all data may be geospatially referenced, research by Hahmann and Burghardt (2013) indicates that about 60% of all data have a spatial reference; i.e. the data can be related to a physical coordinate in a spatial reference system, or identified by a geographic identifier. Systems and their constituents reside in or operate in space and often need to know where they or their parts, constituents, etc. are; where their mobile components go; or where objects observed by the system are. In other words (Longley et al. 2015): “Almost everything that happens, happens somewhere. Knowing where something happens can be critically important.” Extending this observation, potentially the system(s) and their associated constituents require synchronization of their activities and actions which is often achieved by triggering actions via time stamps; for this purpose, systems need to be time-wise synchronized to a certain extent or accuracy. The Geospatial/Geodetic Engineering (GGE) Knowledge Area provides a broad introduction into this overall topic in order to make the reader aware where relevant technologies are actually used in systems. It reflects the abundant uses and applications and even critical dependencies of geodetic and geospatial technologies in systems, such as GNSS & GPS (satellite positioning systems); GIS; spatial reference systems; processing, analysis and visualization (portrayal) of geographic data. It briefly analyzes to what extent the Systems Engineering Specialty Activities listed in the INCOSE Systems Engineering Handbook (2015) and modeling and simulation may be supported by related subject matter expertise. As a consequence it concludes that GGE activities could be considered as dedicated Specialty Engineering activities themselves within Systems Engineering.

Topics

This Knowledge Area includes three topic articles:

- Overview of Geospatial/Geodetic Engineering
- Relationship between Systems Engineering and Geospatial/Geodetic Engineering
- Further Insights into Geospatial/Geodetic Engineering

Overview of Geospatial/Geodetic Engineering

- Lead Author:
- Ulrich Lenk

-

This article is part of the Systems Engineering and Geospatial/Geodetic Engineering (GGE) Knowledge Area. It provides a broad introduction into the overall topic including related applications in order to make the reader aware where GGE is used in systems.

GIS and Geospatial Applications

Perhaps the most comprehensive recent standard textbooks on Geographical Information Systems (GIS) are Longley et al. (2015) and Kresse and Danko (2012). Beyond these two books, there are many others on GIS and respective spatial data capture procedures (surveying, photogrammetry, and remote sensing) and management applications. Tomlinson (2019) and Peters (2012) as well as the online successor to this text book, System Design Strategies [1], provide valuable insights into aspects of how to set up a GIS system. While Tomlinson (2019) looks more at the management perspective and processes of implementing a GIS, Peters (2012) focuses more on technical aspects.

Domain-specific GIS applications are also documented in numerous textbooks. Domain areas include agriculture and forestry, insurance economics and risk analysis, simulation and environmental impact analysis, hydrology, archaeology, ecology, crime investigation and forensics, disaster management and first responders, marketing, municipalities and cadaster, land administration and urban planning, utility sectors, telecommunications, smart cities and military applications. The latter include Command and Control (C2) systems, or are even extended in Command,

Control, Communications, Computers Intelligence, Surveillance and Reconnaissance (C4ISR) systems. Generally speaking, wherever data about events is displayed or portrayed, processed and/or analyzed in a geospatial context, GIS technology is involved. The particular type of user interface doesn't matter. It could be a web interface, a desktop client, or a mobile device such as a smartphone or tablet computer. To provide visualization of this data there must be spatial context for orientation, geographic data such as digital topographic maps, or geographic imagery, Digital Terrain Models (DTM), etc. Beyond such classical geographical data, other types of data are also often used, such as meteorological and other environmental data.

Interoperability is of major concern in geospatial technology. The Open Geospatial Consortium [2] (OGC) is probably the most relevant organization that deals with GIS and sensor systems interoperability. The OGC has published a dedicated set of interface specification standards [3] on their topics.

Positioning, Navigation and Timing

The previous description of geospatial technology focused mostly on stationary objects, i.e. on non-moving geospatial data. This section is mainly concerned with objects in motion, i.e. objects moving in space and with derived applications such as navigation, monitoring, and tracking such objects. The basic operations needed are (geo-)positioning and navigation. Certainly, the majority of people using smartphones are also using various location based services (LBS) that are provided in conjunction with GIS databases and services, such as Google Maps, a well-known online GIS application. As a consequence, positioning and navigation, which are mainly achieved with satellite positioning systems such as Global Navigation Satellite Systems (GNSS), have became ubiquitous and transparent technologies in the last decade. Clearly the most relevant system in common use in the past has been the US Global Positioning System (GPS) since it was the first of its kind. However, it is not the only one of its kind. Russia developed a GNSS called GLONASS; Europe developed the Galileo system which is close to achieving full operating capability; China is working on its Beidhou GNSS. GNSS are used for more than positioning and navigation. Since range measurements conducted by GNSS are based on extremely accurate one-way travel times of signals, these satellites have extremely accurate clocks. GNSS transmit this time for use by other systems, enabling time synchronization of systems and also applications that require frequency normals that can be derived from these time signals. Together, these three GNSS services are called Positioning, Navigation and Timing (PNT). For more on satellite positioning systems and satellite navigation, two excellent sources are Teunissen and Montenbruck (2017) and Hofmann-Wellenhof et al. (2008).

The public does not generally appreciate how many systems used in various domains rely on the availability of GPS/GNSS signals. The majority of national critical infrastructures is now dependent on GNSS (Royal Academy of Engineering 2013; Wallischeck 2016). Thus the availability of open access to GNSS signals is itself considered critical infrastructures. Example infrastructures and applications that depend on GNSS include transport (rail, road, aviation, marine, cycling, walking), agriculture, fisheries, law enforcement, highways management, services for vulnerable people, energy production and management, surveying, dredging, health services, financial services, information services, cartography, safety monitoring, scientific and environmental studies, search and rescue (e.g. as given with the Global Maritime Distress and Safety System, GMDSS), telecommunications, tracking vehicles and valuable or hazardous cargoes, and quantum cryptography (Royal Academy of Engineering 2013).

Geodesy and Geodetic Engineering for Providing the Frameworks for All Spatial Applications

The above sections are application-oriented. However, at a more basic level, all numerical (coordinate-wise) descriptions of natural and man-made stationary and mobile objects, including satellites, need to be referenced to a spatial reference system. It may be a local stationary engineering coordinate reference system, a (moving) internal coordinate reference system that is fixed to an object (in motion), a national spatial reference system, a regional spatial reference system, or even a global spatial reference system, e.g. that given by the World Geodetic System

1984 (WGS84, cf. National Imagery and Mapping Agency 2004), which is the spatial reference system in which GPS works. 2-dimensional ("horizontal") coordinates such as the combination of latitude and longitude in a geodetic coordinate system are fairly straightforward because they are based mainly on mathematical assumptions. The shape of the Earth is approximated by an ellipsoid on whose surface the coordinates are defined, and the ellipsoid is fixed to the Earth via a geodetic datum/geodetic reference frame. Actually also the definition of the ellipsoid itself is part of the geodetic reference frame. Only little input from geophysics is needed (the localization of the rotation axis of the Earth). The third dimension, however, is mostly treated differently. Heights in general are referenced to a reference surface. For ellipsoidal heights this is the ellipsoid, but since ellipsoidal heights can cause confusion as they do not consider the mass characteristics of the Earth with their distribution, it is more common to use heights that are related to a mean sea level (MSL) surface. The latter is mainly dependent on the (irregular!) distribution of masses on Earth and thus on their physical properties. The typical surface used for referencing these gravity-related heights is the so-called geoid which may be approximated by MSL. Beyond these Earth related aspects, however, there are also celestial spatial reference systems and spatial reference systems on other celestial bodies. Torge and Müller (2012) offers more information on these systems. Thus, geodetic engineering with its sub-disciplines of physical and mathematical geodesy together with related engineering disciplines provide fundamental frameworks for various applications in science and technology including systems of systems.

Portrayal of Geographic Data with Map Projections and Cartography

Because people often rely on visual depictions more so than on verbal descriptions, the complicated surface of the Earth typically needs to be “pressed” onto a flat screen, or a map or chart like in traditional cartography, even when it is a 3-dimensional perspective view on a 2D screen. Depending on the display scale, reducing from 3D to 2D cannot be achieved without somewhat or even significantly distorting the shape of the objects. Mathematical geodesy and map projections based on differential geometry provide the basics to achieve these goals (Grafararend et al. 2014). By carefully selecting an appropriate map projection, different characteristics of land masses and applications can be emphasized. One example may be the difference between the classical Mercator projection that is used for nautical charts from the equator up to medium latitudes, and the Stereographic projection that is often used in aeronautics since the shortest distance between two locations there is a straight line. For the Mercator projection, a straight line is a rhumb line, i.e. the line of constant bearing which eases the use of a magnetic compass for steering a vessel (neglecting variations of magnetic declination on Earth). Here, the shortest distance between two points on the Earth’s surface (the geodesic) is a curved line on the chart whose curve is bent towards the pole of the respective hemisphere.

As portrayal of geographic data is a fundamental functionality of GIS, respective map projection modules are generally included in GIS software packages. Beyond these purely projection-related aspects of visualizing geographic data, cartography offers rules and procedures for what to display and how to visualize geographic data. Kraak and Ormeling (2020) show such data may be abstracted by symbols, lines, and areas, including what color and styles to apply to the graphical elements in a map, how to relate these to each other on a screen or paper map, how to generalize them, i.e. how to simplify their shape and depiction or even discard on display, when the scale of display is changed, etc.

Relationship between Systems Engineering and Geospatial/Geodetic Engineering

- Lead Author:
- Ulrich Lenk

-

This article discusses the relationship between Systems Engineering (SE) and Geospatial/Geodetic Engineering (GGE) as reflected through relationships between several Specialty Engineering disciplines listed in INCOSE (2015) and GGE. For most of these disciplines, there are also SEBoK articles in the Knowledge Area SE and Quality Attributes.

Geospatial Aspects in the INCOSE Specialty Engineering Activities

Systems that directly include geospatial components and system elements, or that perform navigation operations or deal with referenceable objects in their broadest interpretations require dedicated contributions from the geodetic/geospatial domain. Those contributions should be achieved by integrating appropriate subject matter experts into SE teams.

The following sections briefly describe possible geospatial solutions or contributions which may directly support some of the Specialty Engineering activities in INCOSE (2015).

Environmental Engineering/Impact Analysis

Analyzing a spatial distribution or dispersal of pollutants typically depends on specific modules that have been integrated into Geographic Information Systems (GIS); e.g. a plume modeler will estimate how chemicals dissolve in the atmosphere under certain meteorological conditions. Other applications determine run-off for flooding simulations, or reveal dependencies between different types of environmental parameters during geospatial analysis. The list of such applications is long. The Knowledge Area (KA) Systems Engineering and Environmental Engineering provides more information.

Interoperability Analysis

Interoperability has been a major issue in geospatial infrastructures for decades. The Open Geospatial Consortium [1] (OGC), founded in 1994, published its first standard (OpenGIS Simple Features Specification) in 1997. Other organizations also publish standards including the International Organization for Standards [2] (ISO) with its Technical Committee 211 Geographic information/Geomatics [3] (see also here [4]), the International Hydrographic Organization [5] (IHO) and the North Atlantic Treaty Organization [6] (NATO). For meteorological data, the World Meteorological Organization [7] (WMO) standardizes respective services and data formats. Typically, these bodies closely cooperate.

Using these standards can lead to significant cost savings in the development and operation of systems and thus contributes to another INCOSE Specialty Engineering activity: Affordability/Cost-Effectiveness/Life Cycle Cost Analysis. NASA funded a study that was conducted by Booz Allen Hamilton (2005). The study found that the project that adopted and implemented geospatial interoperability standards:

- had a risk-adjusted Return on Investment (ROI) of 119.0%. This ROI is a “Savings to Investment” ratio over the 5-year project life cycle.
- had a risk-adjusted Return on Investment (ROI) of 163.0% over a 10-year period.
- saved 26.2% compared to the project that relied upon proprietary standards.

Another finding was that standards-based projects have lower maintenance and operations costs than those relying exclusively on proprietary products for data exchange.

As a general conclusion from the above, there are substantial contributions from the geospatial domain that support interoperability analyses.

Logistics Engineering

According to INCOSE (2015), “Logistics engineering … is the engineering discipline concerned with the identification, acquisition, procurement, and provisioning of all support resources required to sustain operation and maintenance of a system.” Amongst others, the following elements supporting logistics engineering are identified in INCOSE (2015) that have a direct relation to geospatial, GIS and PNT/Global Navigation Satellite Systems (GNSS) technologies:

- Sustaining engineering;
- Training and training support;
- Supply support;
- Facilities and infrastructures; and
- Packaging, handling, storage, and transportation (PHS&T).

Typical keywords associated with related activities are:

- “Technical surveillance” where, e.g., fielded systems are monitored with means of geodetic engineering techniques, such as deformation analysis of structures and sites,
- “Simulation” that requires virtual 3D environments and GIS,
- “Facilities” that are nowadays managed with Building Information Modeling (BIM) techniques which have a close connection to GIS, based on cadastre data from local authorities,
- “Transfer” and “transportation” where objects, material and goods are moved in space involving amongst others GIS with navigable map used for planning routes and navigation during transport.

Sometimes, GNSS and real-time GIS technologies are also used for tracking cargo of interest for safety reasons.

Reliability, Availability, and Maintainability

How reliable is a map, or, in the digitized world, a geographic data set displayed on screen or a mobile device? That depends firstly on the source of data, i.e. how reliable the source is, and on the other hand even for trusted data sources on the need to update that data set according to operational requirements and the changes that take place in the landscape of the area of interest. Updating and otherwise maintaining geospatial databases is a costly and sometimes time-consuming operation (again tied to the Specialty Engineering activity "Affordability/Cost-Effectiveness/Life Cycle Cost Analysis"). Efficiently updating geospatial databases is discussed from a technical perspective in Peters (2012) and, at least to a certain extent, must be reflected as well in the design of a geospatial data infrastructure. Using central services to provision geographic data is one possibility to address this issue since then, only one data set needs to be updated according to the single source of information principle. Others will access this data set via services to always receive the latest version of available data. The required availability constraints clearly must be addressed in the design of the IT infrastructure that hosts such a geospatial database, and also IT security aspects need to be considered.

Resilience Engineering

In recent years there has been an increasing awareness of the vulnerabilities of systems depending on GPS/GNSS. Resilient PNT is heavily discussed and alternatives like eLoran and Satelles are often mentioned in this context. According to the Royal Academy of Engineering (2013), "all critical infrastructure and safety critical systems that require accurate GNSS derived time and or timing should be specified to operate with holdover technology for up to three days." This source also lists other recommendations to be considered for system design.

A source that provides example cases on a regular basis is the Resilient Navigation and Timing Foundation [8] (RNT Foundation). Examples of official reports in the US and the UK are also Wallischeck (2016) and Royal Academy of Engineering (2011). Jamming and GPS disruptions actually occur and sometimes official warnings are issued, e.g. by the US Coast Guard (DHS 2016). According to an RNT Foundation notice [9], there was an official warning from flight authorities during the 2017 G20 event in Hamburg, Germany. It cautioned to consider the possibility of GPS disruptions caused by intentionally initiated activities and actions to protect the G20 conference.

Prudent systems engineers will consider such dependencies and ensure to the degree practical that the systems at hand are resilient and fault tolerant, i.e. those systems do not terminate safe and reliable operation in the absence of GNSS signals, or cause major problems when they need to continue to communicate with other systems.

System Safety Engineering

Although it may not be straightforward, even in System Safety Engineering there are aspects that may be supported by geodetic and surveying engineering. One example may be the monitoring of dams, bridges and buildings etc., i.e. to what extent constructions move under differing environmental conditions, especially when subject to wind or water pressure or heat. Another example is the monitoring of natural objects such as volcanoes or slopes to detect early the possibility of future volcanic eruptions or potential landslides, or the monitoring of fracture zones or areas prone to earthquakes.

Usability Analysis/Human Systems Integration

Geographical displays sometimes form a central part of user interfaces. In such cases, proper usability analysis and other aspects of Human Systems Integration (all of these activities are part of Human Factors Engineering, HFE), geospatial expertise may be required. But beyond this, in HFE several other aspects are considered covering the general interaction of users with systems (Stanton et al. 2013). Nevertheless, in displaying virtual environments, HFE is related to the science and application of cartography (Kraak and Ormeling 2020) because the latter deals not only with portrayal of geographic data but also heavily with the different ways of human perception and abstraction of spatial phenomena, especially in dependence of the different scales the data is displayed.

Geospatial Aspects in Modeling and Simulation

Modeling and simulation is a broad field and heavily used in various disciplines and as such also in different SE life cycle processes. Geospatial technologies contribute to these activities amongst others by providing geographic data to create realistic environments, either for 2- or 3-dimensional applications. According to INCOSE (2015), such a model is then termed a "formal geometric model". When considering temporal aspects and phenomena as well, 4-dimensional models are used. The modeler has to discern what types of geographic information must being modeled, and whether they are discrete objects which can be delimited with boundaries or whether they are continuous fields representing "the real world as a finite number of variables, each one defined at every possible position" (Longley et al. 2015), like temperature. For a comprehensive introduction to the general theory of geographic representation in GIS with continuous fields and discrete objects and how these concepts may be integrated see Longley et al. (2015), Goodchild et al. (2007) and Worboys and Duckham (2004).

In traditional cartography a map model was described by the well-known map legend that explained the portrayal of depicted features or phenomena. Today, fairly straightforward models for perspective visualization of landscapes are created using so-called Digital Terrain Models (DTM) and rendering them with geographic imagery. With these types of models no further descriptive information may be extracted besides geometric information and visual interpretation of the imagery to decide what is actually there. A well-known application for this is Google Earth. Vector models can provide more information. Discrete objects in a vector model may be further described by attributes, e.g. the width of a street. Vector models are created using so-called "feature catalogues" that define which real world objects and domain values are to be represented. A typical military feature catalogue was created by the Defence Geospatial Information Working Group (DGIWG) for worldwide military mapping projects and is called the DGIWG Feature Data Dictionary [10] (DFDD). Feature catalogues vary with different levels of modeling scales, i.e. large-scale models provide a higher granularity than small-scale models that provide more of an overview.

INCOSE (2015) lists the following purposes for models throughout the system life cycle:

- Characterizing an existing system,
- Mission and system concept formulation and evaluation,
- System architecture design and requirements flow-down,
- Support for systems integration and verification,
- Support for training, and
- Knowledge Knowledge capture and system design evolution.

The second and fifth purposes may be supported by geospatial technologies; i.e. data and software components that create, store, simulate and visualize/portray real world or virtual models of environments where a system is going to be deployed, or where operations are going to take place (Tolk 2012). "Mission and system concept formulation and evaluation" tie to the definition of the Concept of Operation (ConOPS). By analyzing different variants of system deployment and categorizing them based on defined cost functions, it is possible to optimize a system design to provide a solid basis for decision making.

Conclusions

Geodetic and geospatial technologies and services play a fundamental role in many systems of systems and stand-alone systems. The general public is often not aware how strongly their lives and activities depend on these assets to provide and maintain critical infrastructure such as electric power and communications services. Against this background, systems engineers often need mastery of GGE knowledge and access to GGE subject matter experts and as a consequence, Geospatial and Geodetic Engineering may be considered as well a Specialty Engineering Discipline for Systems and Systems of Systems Engineering endeavors.

Further Insights into Geospatial/Geodetic Engineering

- Lead Author:
- Ulrich Lenk

-

This article is part of the Systems Engineering and Geospatial/Geodetic Engineering (GGE) Knowledge Area. It discusses in more detail a selected set of topics that a beginner in Geographic Information Systems (GIS) and science or a systems engineer adopting respective techniques might be interested in or should be aware of. Topics discussed include bodies of knowledge on geospatial technologies, various aspects associated with geographic data, and standardization in the geospatial domain.

GIS related Bodies of Knowledge

The emphasis of the article Overview of Geospatial/Geodetic Engineering was to focus on to what extent systems and systems of systems are dependent on GIS related technologies and where potential interfaces or contributions are. In order to provide now an improved but still brief overview of which topics are related in general to geospatial and geodetic engineering and how broad the geospatial domain actually is, a high-level introduction into existing bodies of knowledge in the geospatial domain is provided here.

The work on a body of knowledge (BOK) for the geospatial domain actually goes back into the 1980s (cf. Kemp & Goochild 1991, cited in Stelmaszczuk-Górska et al. 2020), and since then at least two major workstreams have evolved. One in the United States that culminated first in 2006 with the publication of Edition 1 of the Geographic Information Science and Technology Body of Knowledge (GISTBoK) by the University Consortium for Geographic Information Science (UCGIS) [1] (DiBiase et al. 2006). For the Geospatial Intelligence (GEOINT) discipline, a refinement was elaborated by the United States Geospatial Intelligence Foundation (USGIF) [2]. The UCGIS GISTBoK also formed the nucleus for the other workstream in Europe which started with the GI-N2K: Geographic Information – Need to Know [3] project (Vandenbroucke and Vancauwenberghe 2016) that aimed to better reflect European aspects in a BOK and to provide an ontological structure of concepts and relationships (Hofer et al. 2020). The European workstream was then further pursued as part of the Earth Observation for Geoinformation project (EO4GEO) [4] that refined and extended the work from GI-N2K (Stelmaszczuk-Górska et al. 2020; Hofer et al. 2020).

UCGIS: Geographic Information Science and Technology Body of Knowledge (GISTBoK)

For the 2006 GISTBoK a hierarchical decomposition of the geospatial domain was conducted into 10 Knowledge Areas which were again divided into 73 Units and then into 329 Topics. There were over 1600 Learning Objectives listed in these topics. With the update that began in 2013 (Wilson 2014), there are also 10 Knowledge Areas in the current GISTBoK but they have changed partly versus the 2006 version. As of the beginning of 2022, there are 54 Units and 363 Topics. The current Knowledge Areas are:

- Foundational Concepts, with 7 Units and 35 Topics;
- Knowledge Economy, with 4 Units and 20 Topics;
- Computing Platforms, with 5 Units and 28 Topics;
- Programming and Development, with 5 Units and 23 Topics;

- Data Capture, with 8 Units and 35 Topics;
- Data Management, with 7 Units and 53 Topics;
- Analytics and Modeling, with 9 Units and 70 Topics;
- Cartography and Visualization, with 6 Units and 36 Topics;
- Domain Applications, with 44 Topics (with no categorization into Units); and
- GIS&T and Society, with 3 Units and 19 Topics.

It should be noted however that the GISTBoK is constantly evolving and for the latest version the respective GISTBoK online resource [5] has to be checked. Additionally, a feature of this BOK is that many Topics are linked with respective citable articles providing insights into the subjects at hand. The UCGIS also provides at its web site (UCGIS BOK [6]) information on open educational resources on GIS and GIScience.

USGIF: GEOINT Essential Body of Knowledge

Aside from the activities hosted by the UCGIS that were mainly driven by academia, the USGIF published in 2014 the first version of its GEOINT Essential Body of Knowledge that targeted the GEOINT discipline. Among other sources, it was based on the 2006 GISTBoK (DiBiase et al. 2006) but extending it where necessary to better reflect the broader needs of GEOINT and related industries. The second version (Brooks et al. 2019) was published in 2019 after an 18 months period of preparation with a survey in the GEOINT community involving various subject matter experts that interpreted the results of the survey. It serves as a guide to what skills are required in the GEOINT discipline and acts as a blueprint for respective Certified GEOINT Professional exams (Brooks et al. 2019; Baber 2018). The GEOINT Essential Body of Knowledge version 2.0 is divided into three parts. The first one is related to “Technical Competencies” with the following areas:

- GIS & Analysis Tools;
- Remote Sensing & Imagery Analysis;
- Geospatial Data Management; and
- Data Visualization.

The second part is related to “Cross Functional Competencies” which cover general skills like soft skills or common GEOINT knowledge and practices suitable for the GEOINT practitioner, whereas the third part looks at “Emerging Competencies”, like data science, machine learning techniques, virtual reality. artificial intelligence, and unmanned aerial platforms.

It is worth mentioning that, since 2015, USGIF also publishes the “State and Future of GEOINT Reports” on a yearly basis. These may also serve as a general reference on future trends in geospatial technologies.

Europe: The "GI-N2K: Geographic Information - Need to Know" and the "EO4GEO: Earth Observation for Geoinformation" BOKs

The GI-N2K project funded by the European Union's (EU) Erasmus Lifelong Learning Program and its BOK started as well with the 2006 GISTBoK (DiBiase et al. 2006) and had 10 Knowledge Areas. For these Knowledge Areas 63 sub-concepts were identified and further divided into 301 on level 3. However, in some instances level 3 was even further de-composed into level 4 and partly into level 5 concepts. At the end, 411 concepts were defined on these levels. Additional features that were provided with this BOK were curriculum design tools and a GeoWiki to enable discussion between experts.

The most recent development in European GIS-related BOKs is the EO4GEO BOK that continues and further develops as part of the Erasmus+ Sector Skills Alliance project EO4GEO the work conducted in the GI-N2K project. As Earth Observation (EO) and Geoinformation (GI) data sources, especially from the space sector, are gaining nowadays much more importance for data capture and updates of derivative data, the respective skills for data capture, information processing, standalone and combined analysis and associated applications need to be defined and matched or merged with the previous BOKs to reflect this change in academia, business and applications

(Stelmaszczuk-Górska et al. 2020). An analysis revealed that "neither the American nor the European GIS&T (comment: Geographic Information Science and Technology) and GI-N2K BOKs include comprehensive information on EO" (Stelmaszczuk-Górska et al. 2020). Additionally, since there was a criticism that the previous BOKs were too much oriented along education driven by academia and too theoretical with a lack of practical aspects, an emphasis was made to “better align” the academically oriented EO4GEO BOK “with the business, professional, and industrial perspective” (Hofer et al. 2020) by analyzing a set of relevant business processes with regard to applicable concepts.

The EO4GEO BOK [7] has at its highest level 14 subconcepts as follows:

- Analytical Methods, with 14 subconcepts;
- Conceptual Foundations, with 8 subconcepts;
- Cartography and Visualization, with 6 subconcepts;
- Design and Setup of Geographic Information Systems, with 4 subconcepts;
- Data Modeling, Storage and Exploitation, with 5 subconcepts;
- Geocomputation, with 4 subconcepts;
- Geospatial Data, with 4 subconcepts;
- GI and Society, with 6 subconcepts;
- Image processing and analysis, with 6 subconcepts;
- Organizational and Institutional Aspects, with 5 subconcepts;
- Physical principles, with 2 subconcepts;
- Platforms, sensors and digital imagery, with 4 subconcepts;
- Thematic and application domains, with 5 subconcepts; and
- Web-based GI, with 7 subconcepts.

Similar as with the GIN-2K BOK, there are partly also further levels below the subconcepts. In addition to the BOK, it provides an occupational profile tool, a job offer tool, a curriculum design tool, a BOK annotation tool, a BOK matching tool and other educational features. For the concepts, their names are given along with descriptions and references. A set of 5 relationships between the concepts is maintained, and skills explaining the practical use of the EO*GEO knowledge are associated with the concepts (Hofer et al. 2020). The BOK exploration is supported by a graphical tool.

Geographic Data and Metadata

Geographic Data

Geospatial data is actually the fuel needed for any type of geographic application, whether it might be only for visualization purpose, e.g. as background information for real-time situational awareness applications, or for advanced spatial analytics involving different data sources and specific analysis methods. A first categorization into the two fundamental concepts of geographic data has already been given in the SEBoK article Relationship between Systems Engineering and Geospatial/Geodetic Engineering. They are:

- Continuous fields, i.e. spatially distributed phenomena with no clear limits or boundaries and representing “the real world as a finite number of variables, each one defined at every possible position” (Longley et al. 2015). For the case that repeated pattern of positions is used, the term raster data is commonly used, especially for the case that an equidistant matrix pattern is used. However, a matrix could potentially have different resolutions in columns and rows, or theoretically also other regular patterns could be involved, such as hexagonal patterns, but these applications are very rare.
- Discrete objects or features, which are delimited by boundaries and potentially associated with a set of attribute data to describe them further beyond their spatial properties. This type of data is also termed vector data in a GIS context.

Beyond these two fundamental concepts, the different aspects that need to be considered for geographic data when designing a system using this data are very diverse and cannot be treated in full detail here. A selection of important key words coming from practical experiences to be considered when implementing GIS databases include:

- What data is actually needed (examples see below)?
  - At what scales shall the data be visualized, i.e. the level of detail needed.
  - Dimensionality: typical dimensionalities used in GIS technologies are:
    - 2D, describing the earth surface in a flat plane, like a paper map;
    - 2.5D, with a unique z-value to a position in the horizontal plane;
    - 3D, where all three dimensions are considered; and
    - Time dimension: for the case of 3D data then 4D, but as also the former 2 cases may have variations in time this is treated here as time dimension.
  - What are the critical infrastructures that need to be shown, such as transport networks?
- What standards need to be considered, such as feature catalogues, interface and data format standards, data acquisition standards etc.?
- What is the positional accuracy required for the geographic data? This is typically associated with data acquisition method to be selected and obviously with the costs involved.
- What is the level of semantic detail needed, e.g. how many feature attributes shall be captured for features / vector data and how big is the set of domain values from which they shall be selected?
- Are there complex topological relations to be captured and maintained, i.e. to establish connectivity for the vector data, for example, for routing applications or utility networks?
- Questions on updates:
  - How often does the data need to be updated? This is directly related to maintenance costs for the database, i.e. recurring costs to be considered, but also to availability of resources for the updates.
  - How shall the data be updated? Is it possible to use a central service for the data which is updated, i.e. can the responsibility for the updates be delegated?
  - What communication lines are used when data and updates are distributed in a system? Or is a service model the better choice as it realizes a single source of information principle? A systems engineers has to keep in mind that geographic data can reach considerable data volumes (depending on type of data terabytes and petabytes) that cannot be easily distributed over the air for example.
- What are the data sources that may or have to be used? How are bounding conditions on the use of the data?
  - Authoritative data from a spatial data infrastructure, from international or national governmental agencies (or even intergovernmental agencies), such as national surveys like the USGS or the British Ordnance Survey, or on an international level the United Nations.
  - Commercial data sources, such as satellite imagery service providers, or mapping service providers.
  - Open sources, from activities like the Open Street Map [8] or Open Seamap [9] initiatives.
  - Copyrights and Intellectual Property Rights associated with the data sources.
  - Classification of data.
  - Bounding legal conditions (e.g. export control laws and regulations for export of data, as for example some satellite image resolutions may have export restrictions).
  - Liability aspects for the data, especially for the cases of legal boundaries, i.e. national borders. This is of particular relevance when borders are under dispute between neighboring countries!

For implementation aspects again Tomlinson (2019) and Peters (2012) are referred to as well as the online successor to the latter text book, System Design Strategies [1].

Metadata for Geographic Data

Whereas the section above discusses aspects of geographic data itself, it is also of fundamental importance to make this data available to or detectable by potential users. This is done by describing the data by metadata and having the metadata available, for example in a catalog where users can search for it. Whereas the Dublin Core data set (ISO 2017; ISO 2019b) defined by the Dublin Core Metadata Initiative is now used to describe general items, for the special case of geographic data, a set of dedicated ISO standards has been developed (ISO 2014, with its amendments ISO 2018 & ISO 2022; ISO 2020d). As such, ISO 19115 "provides information about the identification, the extent, the quality, the spatial and temporal aspects, the content, the spatial reference, the portrayal, distribution, and other properties of digital geographic data and services" (ISO 2014).

Geocoding Systems, Localization and Geographic Search

One further particular aspect looked at here is how a spatial reference for a feature may be expressed. Certainly the most well-known way to describe a location technically or mathematically is by coordinates, either in 2 dimensions for the simple case of a plane, or in 3 dimensions or even adding a time dimension. Standardized ways to express geographic coordinates are covered by ISO 6709 (ISO 2009) but also Cartesian coordinate systems are in use. However, a spatial reference may also be given by other types of geographic identifiers where a location is expressed by a specific (sometimes non-numeric) code or name. A gazetteer is used to manage geographic identifiers, such as geographic names, e.g. names of states, provinces, or other geographically identifiable features such as lakes etc. Other codes in use are for example addresses (where it should be remembered that there are also different postal address types in use), country codes (ISO 3166-1, ISO 2020a) and codes of country principal subdivisions such as states and provinces (ISO 3166-2; ISO 2020b), but there are many other, sometimes application or domain specific or even commercially developed geocodes.

An example of a commercially developed and thus proprietary geococde is the What3words [10] system that is even in use as a postal addressing system in some countries. By dividing the Earth's surface into squares of about 3 meters by 3 meters and assigning unique 3 ordered words to each of them, the codes for each location are established. There are, however, several other systems available, like Geohash [11] or Mapcode [12], which have no license restrictions.

In general, geocodes may be categorized into non-hierarchical and hierarchical geocodes, while for the latter the accuracy of location position increases in a refinement/subdivision process, similar to adding more significant digits to a coordinate. A well-known dataset of geographic names often used in GIS applications is provided by geonames.org [13].

These codes can then also be used to navigate in a geographic display, i.e. by inserting a geocode one can jump directly in the display to the respective position or features (described by positions) associated with the code. In case the code is ambiguous (as it is sometimes the case for geographic names like city names) a disambiguation could be given, in order to clarify the selection. While this approach is mainly used to navigate in a display or to find a location, it should not be confused with the topic of efficiently searching in multidimensional spatial databases. This is not treated here as it relates to database management system design and implementation, including spatial indexing, for example with space filling curves.

Example: The United Nations 14 Global Fundamental Geospatial Data Themes

The set of geographic data to be used in a system will always be dependent on the purpose and goals of the system at hand, and therefore no general purpose structure can be provided here. Some examples of geographic data have already been given in the SEBoK article Relationship between Systems Engineering and Geospatial/Geodetic Engineering in the frame of Geospatial Aspects in Modeling and Simulation. In order to extend this for a better and broader overview of what may considered as relevant in general, the following list of geospatial data themes may serve as a first indicator. It has been elaborated as "The 14 Global Fundamental Geospatial Data Themes" by the United Nations Committee of Experts on Global Geospatial Information Management (UN-GGIM 2019).

- Global Geodetic Reference Frame;
- Addresses, such as postal addresses, see above;
- Buildings and Settlements;
- Elevation and Depth, e.g. provided by Digital Elevation Models and Digital Terrain Models (DTM);
- Functional Areas, such as administrative or legislative areas;
- Geographical Names, e.g. geographic identifiers managed and provided by a gazetteer, see above;
- Geology and Soils;
- Land Cover and Land Use;
- Land Parcels, e.g. a cadastre or a land register;
- Physical Infrastructure, including industrial and utility facilities;
- Population Distribution;
- Orthoimagery, which is a special case of geographic imagery in orthogonal projection;
- Transport Networks, e.g. rails, roads, waterways and air transport routes associated potentially with connectivity relations; and
- Water, including rivers, lakes and marine features.

The UN-GGIM (2019) provides more insights and information into the themes, e.g. what standards are available and possible sources for data. In GIS where often multiple geographic data sets from different sources are processed in a combined way, these data sets are organized into a stacked set of layers which may be for example switched on and off individually for visualization purpose.

Standardization Organizations active in the Geospatial Domain

In the following selected international civil organizations are briefly introduced that publish standards related to the geospatial domain.

The Open Geospatial Consortium (OGC)

The Open Geospatial Consortium (OGC) was founded in 1994 and publishes open standards and specifications in the geospatial domain. The documents are created in a member-driven consensus process. The most successful standards are the Web Map Service (WMS; OGC 2006) and the Web Feature Service (WFS; OGC 2010), but OGC has published about 70 implementation standards and about 20 abstract specifications.

OGC works closely with ISO TC211 (see next section), and some documents are jointly elaborated and published. For example, the above mentioned WMS is also an ISO standard (namely ISO 2005), as is the WFS (ISO 2010). Another example is the specification of the Geography Markup language (OGC, 2012; and ISO, 2015 & 2020a) that is published by both OGC and ISO. Special care has to be taken which version is published in which document since they are not necessarily published in the same versions at the same time. Besides the cooperation with ISO TC211, OGC has in addition other alliance partners, such as the Object Management Group (OMG), the Organization for Advancement of Structured Information Standards (OASIS), the Web3D Consortium, the World Wide Web Consortium (W3C), the International Hydrographic Organization (IHO) and the World Meteorological Organization (WMO) (both see below), and also with other ISO TCs.

Several companies well-known to the general public such as Amazon Web Services, Apple, Google, Microsoft, Oracle and SAP, and universities, governmental, inter-governmental and non-governmental organizations as well as individuals are members of the OGC at different levels of membership, summing up to more than 500 members.

ISO TC 211 "Geographic information/Geomatics"

The International Organization for Standardization (ISO) is certainly the best known international standardization organization in the world and is organized into technical committees which develop the standards. The Technical Committee (TC) 211 is related to "Geographic information/Geomatics". TC211 has published more than 80 standards, most of them as part of the 191xx family of standards, including abstract specifications and interface standards together with the OGC. Several ISO TC211 standards are referenced in the list of references below. TC211 also maintains the Online Multi-Lingual Glossary of Terms (MLGT) [14] at Geolexica that was used to define terms used in this Knowledge Area. Typically ISO standards are also promulgated as national standards, or as European standards from the respective European standardization organizations.

International Hydrographic Organization (IHO)

Founded in 1921 as the International Hydrographic Bureau and renamed in 1970 to the International Hydrographic Organization (IHO), IHO is an intergovernmental organization that standardizes and coordinates activities in the area of hydrography, nautical cartography and thus nautical charts to ensure initially and still primarily the safety of navigation. With the increasing interest in the marine environment, e.g. for the installation of offshore wind farms, the importance of the activities of IHO has even more increased as it publishes standards for the creation and exchange of digital hydrographic data (IHO 2020; IHO 2017a; IHO 2000, with its appendices) that may serve as a GIS base map layer, and also for the portrayal of data (IHO 2014). The way how hydrographic offices can support the creation of spatial data infrastructures by providing data for the marine environment is discussed in IHO (2017b). With the revision of its standards to adhere to ISO TC211 standards, IHO is now transitioning to the S-100 family of standards (IHO 2018).

World Meteorological Organization (WMO)

Originally founded in 1873 as the International Meteorological Organization and renamed in 1950 into the World Meteorological Organization (WMO), WMO is an intergovernmental organization and specialized agency of the United Nations. According to its mandate as described on its website [15], it provides the framework for international cooperation "in the areas of meteorology (weather and climate), operational hydrology and related geophysical sciences" and facilitates "free and unrestricted exchange of data and information, products and services in real- or near-real time on matters relating to safety and security of society, economic welfare and the protection of the environment." WMO defines several data formats for the exchange of weather information (WMO 2019 & 2021a/b).

Clearly the scientific background needed to create meteorological information goes far beyond of what is needed in standard GIS applications. From a GIS perspective, weather information may be treated as one or several information layer(s), and due to the typically required real- or near-real time information respective online interfaces have to be established with weather data providers, whether they are national weather services or commercial companies.

Knowledge Area: Systems Engineering and Industrial Engineering

Systems Engineering and Industrial Engineering

- Lead Author:
- Gregory S. Parnell
- Contributing Authors:
- C. Robert Kenley and Eric Specking, Ed Pohl

-

Systems Engineering (SE) overlaps with many fields, such as Industrial Engineering (IE), Engineering Management, Operations Research, Project Management, and Design Engineering. In fact, the main Industrial Engineering body of knowledge, called the Industrial and Systems Engineering Body of Knowledge (ISEBoK) (IISE 2021), includes the word "systems" in its title and includes a section on systems design and engineering, which references the SEBoK. This article describes the similarities and differences between SE and IE based upon their respective standards, handbooks, and bodies of knowledge. Based on this assessment, this article describes potential roles that systems engineers and industrial engineers perform during a system's life cycle.

Introduction

When systems engineers and industrial engineers are in the same organization, they have different roles and responsibilities. While job titles vary by organization, many organizations have individuals that perform both SE and IE activities. This article tries to help systems engineers and industrial engineers better understand the different perspectives of the fields and the knowledge needed to meet the needs of their organizations and customers. The article compares the use of international standards and the contents of the bodies of knowledge for SE and IE.

Systems Engineering

The International Council on Systems Engineering (INCOSE) is a "not-for-profit membership organization founded to develop and disseminate the interdisciplinary principles and practices that enable the realization of successful systems." INCOSE defines systems engineering as

> *a transdisciplinary and integrative approach to enable the successful realization, use, and retirement of engineered systems, using systems principles and concepts, and scientific, technological, and management methods. (INCOSE 2021)*

Here, the terms "engineering" and "engineered" are used in their widest sense: "the action of working artfully to bring something about." "Engineered systems" may be composed of any or all of people, products, services, information, processes, and natural elements.

INCOSE aligns its SE Handbook with ISO/IEC/IEEE 15288, System Life Cycle Processes, which focuses on processes. SEBoK Part 3 Systems Engineering and Management, which addresses the major SE technical and management processes, is also organized around 15288 process areas. In this view, SE is process oriented. Each edition of the SE Handbook aligns to an ISO/IEC/IEEE 15288 edition. Figure 1 shows the 15288 processes and how they align with the SE Handbook and SEBoK topic areas. Later in this article, these SEBoK topics and knowledge

areas are compared with the knowledge areas of IE. The knowledge areas in Figure 1 align with the system life cycle if started at the top of the first column and traversed to the bottom, continued at the bottom of the second column and traversed to the top, and then continued at the bottom of the third column and traversed to the top.

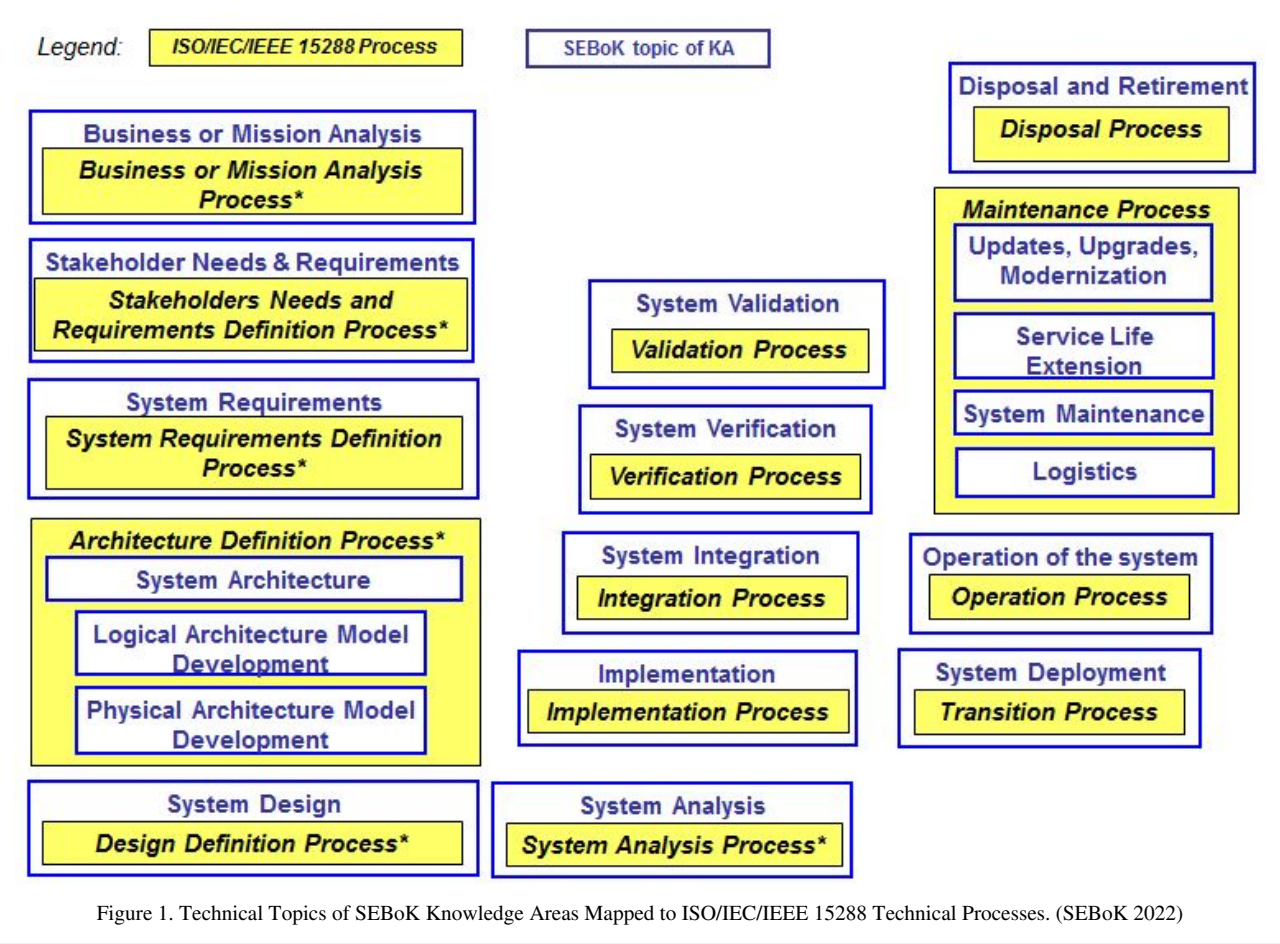

Figure 1. Technical Topics of SEBoK Knowledge Areas Mapped to ISO/IEC/IEEE 15288 Technical Processes. (SEBoK 2022)

Industrial Engineering

The Institute of Industrial and Systems Engineers (IISE) states that it is “the only international, non-profit, professional society dedicated to advancing the technical and managerial excellence of industrial engineers.” (IISE 2021). IISE started in 1948 as the American Institute of Industrial Engineers. In 1981, the organization was renamed the Institute of Industrial Engineers to reflect its growing international membership. In 2016, the membership voted to change the name to the Institute of Industrial and Systems Engineers. This addition reflects a vote by its membership and aligns with the “changing scope of the profession that, while keeping its industrial base, has seen more industrial and systems engineers working with large scale integrated systems in a variety of sectors”.

At the turn of this century, industrial engineering was well reflected in two prominent publications: *Handbook of Industrial Engineering* (Salvendy 2001) and the fifth edition of *Maynard's Industrial Engineering Handbook* (Zandin 2001). Salvendy (2001) stated that industrial engineers are trained to design and analyze the components of which man-machine systems are composed. They bring together individual elements that are designed via other engineering disciplines and properly synergize these subsystems together with the people components for a completely integrated man-machine system. Industrial engineers are focused on the improvement of any system that is being designed or evaluated. They make individual human tasks more productive and efficient by optimizing flow, eliminating unnecessary motions, utilizing alternate materials to improve manufacturing, improving the flow of product through processes, and optimizing the configuration of workspaces. Fundamentally, the industrial engineer is charged with reducing costs and increasing profitability through ensuring the efficient use of human, material,

physical, and/or financial resources.

The view of IE has evolved over the last two decades. IISE developed the IISE Body of Knowledge in 2021 (IISE 2021). The sixth edition of *Maynard's Industrial Engineering Handbook* (Zandin 2022) is expected to be published in 2022. The IISEBoK has 14 knowledge areas, as shown in Figure 2. The first 13 knowledge areas identify the Industrial Engineering knowledge. The fourteenth is Systems Design and Engineering, which references the SEBoK. The IISEBoK provides a short description of each knowledge area, a detailed outline of knowledge area topics, and a list of references. The IISEBoK does not use standards as its foundation. In fact, the Standard Practice for Systems Safety (MIL-STD-0-882D) is the only standard cited in the reference section. IISE does not currently have a handbook developed by or for the Institute, although Zandin (2022) is expected to align with the IISEBoK.

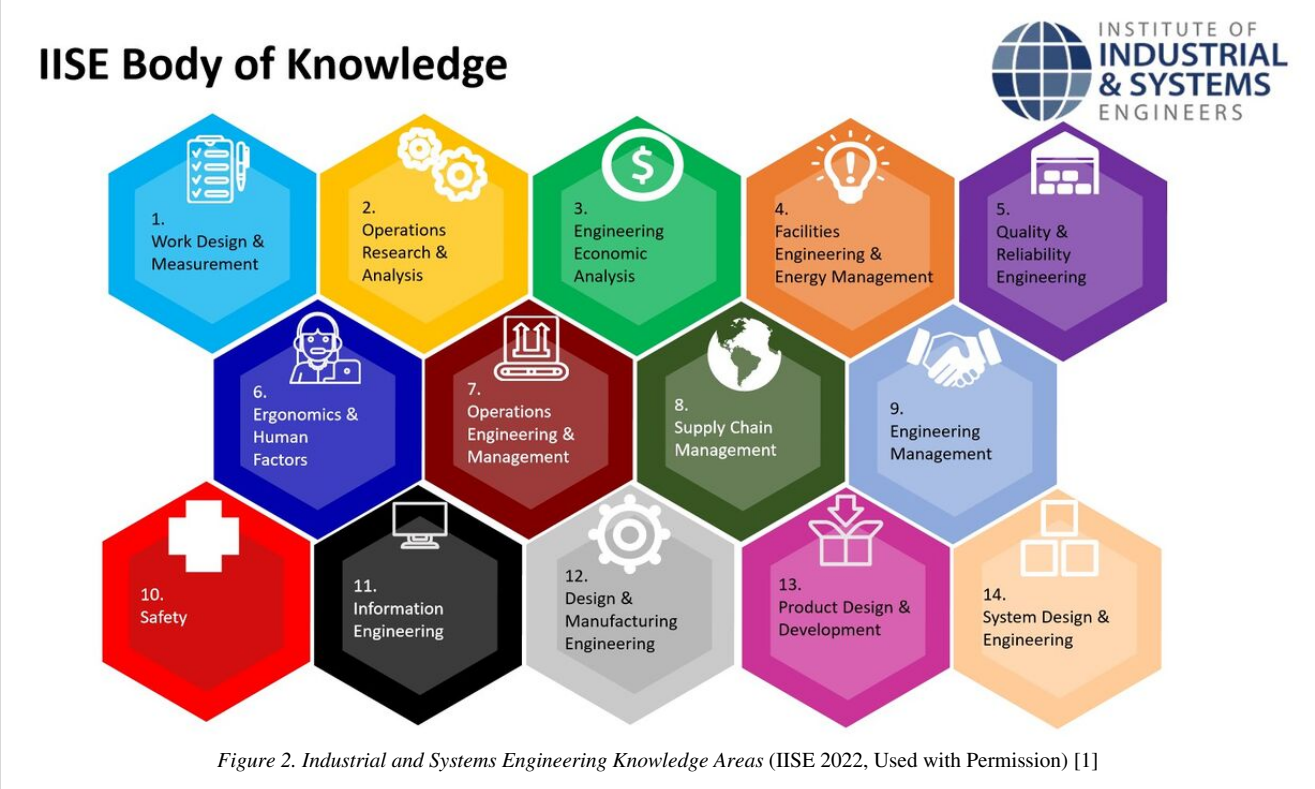

Figure 2. Industrial and Systems Engineering Knowledge Areas (IISE 2022, Used with Permission) [1]

The 14 topic areas included in the IISEBoK could be tied to many international standards even though the IISEBoK does not use standards as its foundation or provide references to standards in most of its topic areas.

Venn Diagram Comparison

This section compares the two bodies of knowledge. Figure 3 is a Venn Diagram that identifies knowledge areas that are usually performed by systems engineers, ones usually performed by industrial engineers, and ones that are used by both disciplines.

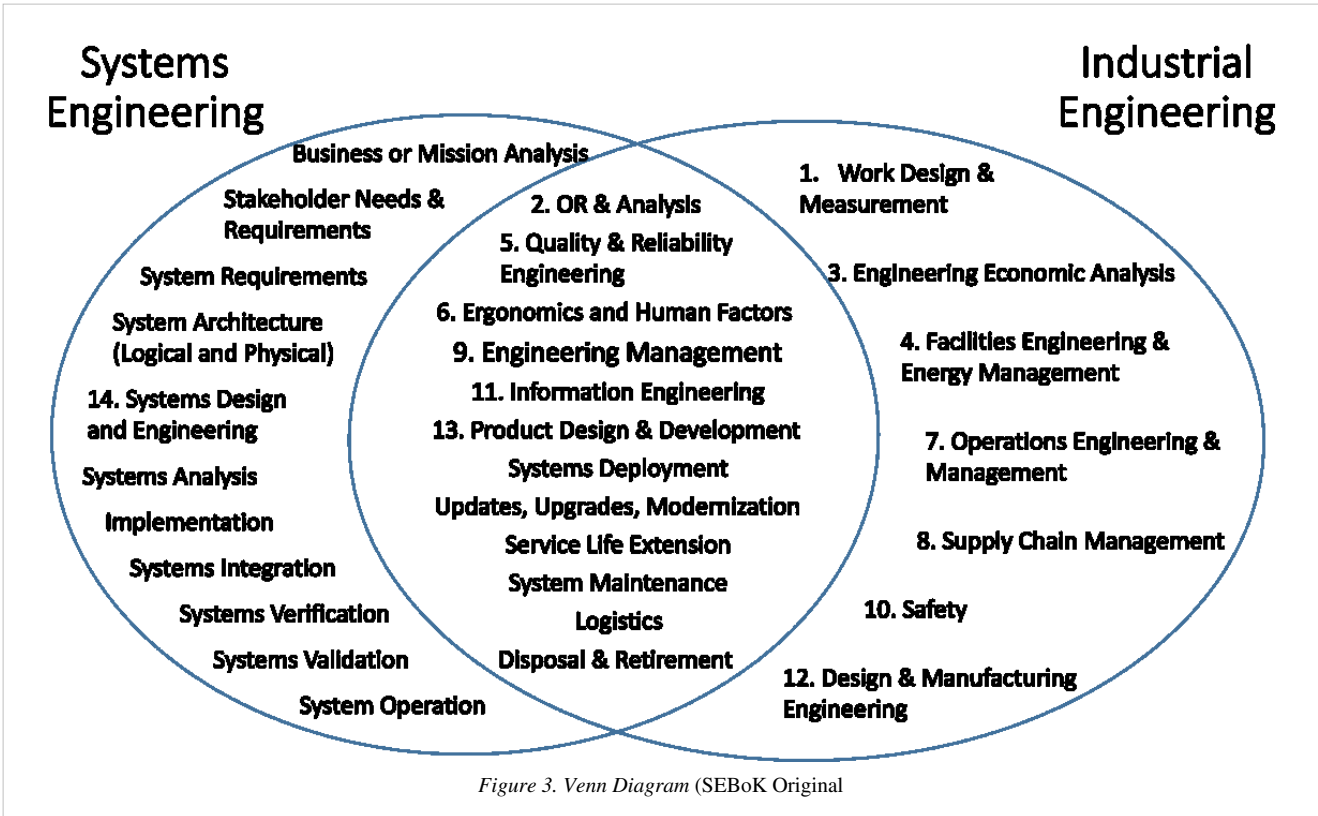

Figure 3. Venn Diagram (SEBoK Original

There are 11 primarily SE knowledge areas, 7 primarily IE knowledge areas, and 12 overlapping knowledge areas. Table 1 provides some illustrative examples of the differences in SE and IE focus in the overlapping knowledge areas.

Table 1. Illustrative Examples of Differences in SE and IE Focus

Knowledge Area	Systems Engineering Focus	Industrial Engineering Focus
2. Operations Research (OR) and Analysis	OR and analysis is used in systems analysis to assess system performance and to evaluate system designs (Levis and Wagenhals 2000; Wagenhals, Shin, Kim, and Levis 2000; Wagenhals, Haider, and Levis 2003; Raz, Kenley, and DeLaurentis 2018)	OR and analysis is used to optimize operations, maintenance, and logistics. OR is also used to evaluate and optimize manufacturing systems.
5. Quality & Reliability Engineering	Quality and reliability requirements are treated as system-wide performance requirements (Buede and Miller 2016: 157-159; Wymore 1993: 401) that are assessed at the systems level. One example is availability, A_0, which measures the degree to which a system is either operating or can operate at any time when used in its typical operational and support environment. (DA PAM 70-3 2008: 87)	Quality and reliability are used to evaluate and improve the manufacturing process of goods and services. Reliability is also used to evaluate and improve system operations.

6. Ergonomics and Human Factors	Ergonomics and human factors are considerations in assessing the potential usability of a system for end-users in an operational environment. According to Buede and Miller (2016: 180), "Performance elements of usability are ease of learning (learnability), ease of use (efficiency), ease of remembering (memorability), error rate, and subjectively pleasing (satisfaction)."	Ergonomics and human factors are used to assess and improve manufacturing and operational processes. They are also used to assess and improve the actual usability of products and services.
9. Engineering Management	Engineering managers and SEs work with program managers to develop and improve new products and services.	Engineering managers and IEs support operations managers responsible for manufacturing processes and the operation of systems providing products and services.
11. Information Engineering	Information Engineering is critical to the development of new products and services that are increasingly software intensive. Information engineering is relevant for model-based systems engineering software tools and databases, requirements management software tools and databases, and overall configuration management of the systems design and requirements baseline.	The Information Engineering knowledge area focuses on using data in information systems to facilitate decision-making and business communication.
13. Product Design and Development	SE focuses on the design of systems that provide products and services and the system life cycle. SE includes the technical processes for system design and verification and the technical management processes for project planning, assessment, and control; risk management; and decision management in the *Systems Engineering Handbook* (2015: 47-83, 104-121).	The knowledge area of the ISEBoK (2021: 53-46) focuses on the design of products and the product life cycle. It closely parallels the technical processes for system design and development of SEBoK.
Systems Deployment	Systems engineers participate in defining requirements, defining the architecture, and verification and validation of deployment systems needed to the deploy the system of interest, e.g., special transport equipment such as the Shuttle Carrier Aircraft (SCA) that NASA used to transport Space Shuttle orbiters. (Jenkins 2000)	Industrial engineers are more focused on air, ground, water, and intermodal logistics to include transportation and distribution of systems and products.
Updates, Upgrades, Modernization	Systems engineers are involved defining requirements, defining the architecture, and verification and validation of updates, upgrades, and modernization of systems. One way that this has been explained is that a second iteration of the systems engineering V-model is completed as the systems remains in service while a system change project is implemented (Ven, Talik, and Hulse 2012).	Industrial engineers are involved in manufacturing processes and supporting operations of systems to provide goods and services. Industrial engineers can help identify the need for updates, upgrades, and modernization of manufacturing and service processes and work with engineering managers, systems engineers, and design engineers to provide improved capabilities.
Service Life Extension	Systems engineers are involved in service life extension efforts in the same way that they are involved in updates, upgrades, and modernization of systems.	Industrial engineers are involved in service life extension efforts in the same way that they are involved in updates, upgrades, and modernization of systems.
System Maintenance	Systems engineers participate in defining requirements for maintenance across the life cycle of the system, determine the impact of maintenance constraints on the system requirements and the system architecture (Walden, et al. 2015: 97-98).	Industrial engineers provide engineering support to production processes maintenance and system maintenance to sustain operation of production and service processes and systems.
Logistics	Systems engineers participate in defining requirements for logistics across the life cycle of the system, determine the impact of maintenance constraints on the system requirements and the system architecture (Walden, et al. 2015: 97-98).	Industrial engineers are very involved in logistics planning and operations including supply chain management, transportation, and distribution.
Disposal and Retirement	Systems engineers identify requirements, define the architecture, and verification and validation of disposal and retirement needed to the disposition or retire the system of interest, e.g., nuclear material stabilization processes and equipment needed to disposition fissile nuclear materials to enable shutdown of the nuclear production facilities (Kenley, et al. 1999).	Industrial engineers plan for disposal and retirement as part of their product design process. Increasingly, industrial engineers must consider environmental impact and sustainability issues.

Roles in a System Life Cycle

Systems engineers and industrial engineers play important roles in a system life cycle. Figure 4 modifies a format from Buede and Miller (2016). It shows the system life cycle stages and, based on analysis in the previous section, identifies and summarizes the major roles of systems engineers, industrial engineers, and design engineers. Some processes have been aggregated to simplify the figure.

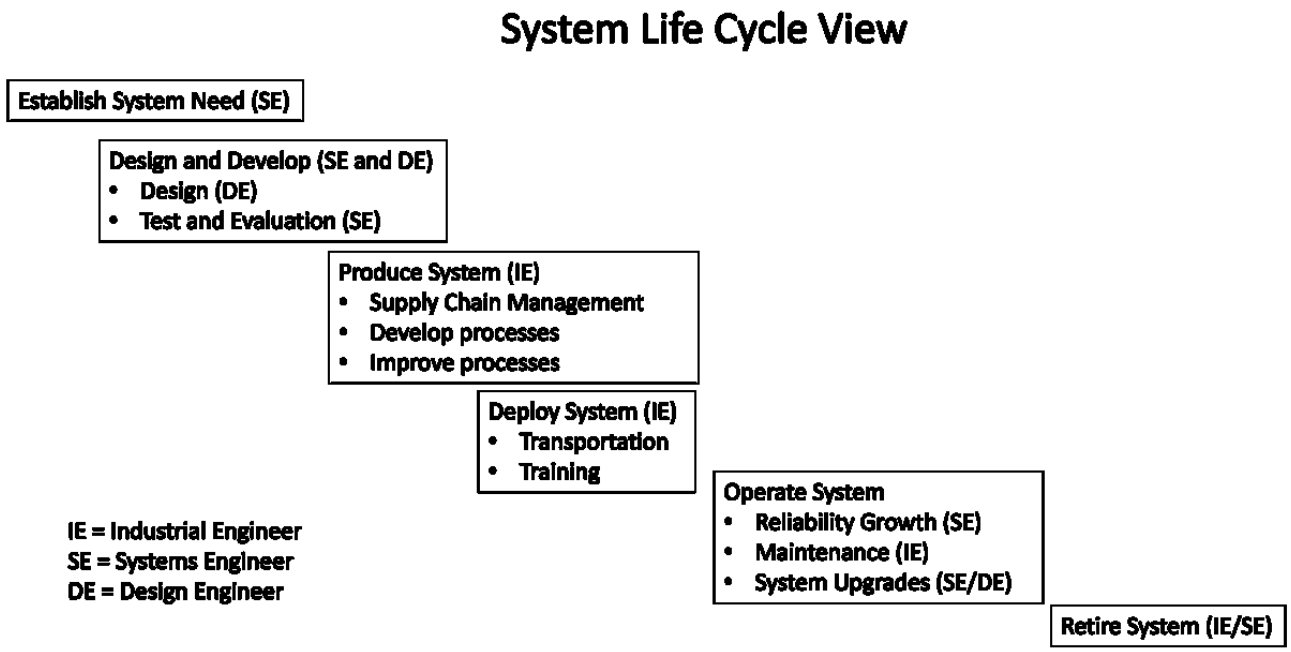

Figure 4. Roles in a System Life Cycle. (SEBoK Original, adapted from Driscoll 2011)

Summary

In summary:

- The SEBoK *SE and Management* Part is based on an ISO standard. IE has several related ISO standards. IISE does not link its body of knowledge to standards.
- The SEBoK is more process focused, while IISEBoK focuses more on concepts and techniques.
- SE and IE have overlapping bodies of knowledge.
- The SEBoK and INCOSE's SE Handbook align with the system life cycle. The IISEBoK does not have an analogous organizing structure.
- Systems engineers and industrial engineers both play important roles in the system life cycle with some overlapping responsibilities.

Systems Engineering and Project Management

Contents of this Knowledge Area

- The Nature of Project Management (Heidi Davidz) (Richard Turner and Alice Squires)
- An Overview of the PMBOK® Guide (Richard Turner) (Alice Squires)
- Relationships between Systems Engineering and Project Management (Richard Turner) (Alice Squires)
- The Influence of Project Structure and Governance on Systems Engineering and Project Management Relationships (Alice Squires)
- Cost Estimating and Analysis in Systems Engineering (Gan Wang)
- Procurement and Acquisition (Dick Fairley) (Alice Squires)
- Portfolio Management (Eric Specking, Gregory S. Parnell, and Ed Pohl)
- Lead Author:
- Dick Fairley
- Contributing Authors:
- Richard Turner and Alice Squires
-

The goal of project management is to plan and coordinate the work activities needed to deliver a satisfactory product, service, or enterprise endeavor within the constraints of schedule, budget, resources, infrastructure, and available staffing and technology. The purpose of this knowledge area (KA) is to acquaint systems engineers with the elements of project management and to explain the relationships between systems engineering (SE) and project management (PM).

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs, in turn, are divided into topics. This KA contains the following topics:

- The Nature of Project Management
- An Overview of the PMBOK® Guide
- Relationships between Systems Engineering and Project Management
- The Influence of Project Structure and Governance on Systems Engineering and Project Management Relationships
- Cost Estimating and Analysis in Systems Engineering
- Procurement and Acquisition
- Portfolio Management

The Nature of Project Management

- Lead Author:
- Heidi Davidz
- Contributing Authors:
- Richard Turner and Alice Squires

-

While *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)* provides an overview of project management for those seeking PMI certification, Fairley (2009) and Forsberg (2005) suggest another way to characterize the important aspects of project management:

- Planning and Estimating
- Measuring and Controlling
- Leading and Directing
- Managing Risk

Introduction

Project managers and systems engineers are both concerned with management issues such as planning, measuring and controlling, leading, directing, and managing risk. In the case of project managers, the project attributes to be managed include project plans; estimates; schedule; budget; project structure; staffing; resources; infrastructure; and risk factors. Product attributes managed by systems engineers include items such as requirements allocation and flow-down; system architecture; structure of and interactions among technical teams; specialty engineering; integration; verification; and validation.

The exact allocation of the SE and PM duties depend on many factors, such as customer and stakeholder interactions, organizational structure of the parent organization, and relationships with affiliate contractors and subcontractors. (See the article on The Influence of Project Structure and Governance on Systems Engineering and Project Management Relationships in this KA.)

Planning and Estimating

Planning

Project Planning a project involves providing answers to the who, what, where, when, and why of every project:

- **Who:** Addresses staffing issues (competencies, numbers of staff, communication and coordination)
- **What:** Addresses the scope of activities
- **Where:** Addresses issues of locale (local, geographically distributed)
- **When:** Addresses scheduling issues
- **Why:** Addresses rationale for conducting a project

Guidance for developing project plans can be found in INCOSE (2012), NASA (2007), and ISO/IEC/IEEE Standard 16326:2009. It is often observed that communication and coordination among stakeholders during project planning are equally as important as (and sometimes more important than) the documented plan that is produced.

In defense work, event-driven integrated master plans and time-driven integrated master schedules are planning products. Chapter 11 of the Defense Acquisition Guidebook provides details (DAU 2010).

Estimating

Estimation is an important element of planning. An estimate is a projection from past to future, adjusted to account for differences between past and future. Estimation techniques include analogy, rule of thumb, expert judgment, and use of parametric models such as the PRICE model for hardware, COCOMO for software projects and COSYSMO for systems projects (Stewart 1990; Boehm et al. 2000; Valerdi 2008).

Entities estimated include (but are not limited to) schedule, cost, performance, and risk.

Systems engineering contributes to project estimation efforts by ensuring that:

- the overall system life cycle is understood;
- dependencies on other systems and organizations are identified;
- the logical dependencies during development are identified; and
- resources and key skills are identified and planned.

Additionally, high-level system architecture and risk assessment provide the basis for both the work breakdown structure and the organizational breakdown structure.

Measuring and Controlling

Measuring and controlling are the key elements of executing a project. Measurement includes collecting measures for work products and work processes. For example, determining the level of coverage of requirements in a design specification can be assessed through review, analysis, prototyping, and traceability. Effort and schedule expended on the work processes can be measured and compared to estimates; earned value tracking can be used for this purpose. Controlling is concerned with analyzing measurement data and implementing corrective actions when actual status does not align with planned status.

Systems engineers may be responsible for managing all technical aspects of project execution, or they may serve as staff support for the project manager or project management office. Organizational relationships between systems engineers and project managers are presented in Team Capability. Other organizational considerations for the relationships between systems engineering and project management are covered in the Enabling Systems Engineering knowledge area.

Additional information on measurement and control of technical factors can be found in the Measurement and Project Assessment and Control articles in Part 3: Systems Engineering and Management.

Leading and Directing

Leading and directing requires communication and coordination among all project stakeholders, both internal and external. Systems engineers may be responsible for managing all technical aspects of project execution, or they may serve as staff support for the project manager or project management office. Organizational relationships between systems engineers and project managers are presented in the article Team Capability in Part 5. Other organizational considerations for the relationships between systems engineering and project management are discussed in Part 5: Enabling Systems Engineering.

Managing Risk

Risk management is concerned with identifying and mitigating potential problems before they become real problems. Systems engineering projects are, by nature, high-risk endeavors because of the many unknowns and uncertainties that are inherent in projects. Because new risk factors typically emerge during a project, ongoing continuous risk management is an important activity for both systems engineers and project managers.

Potential and actual problems may exist within every aspect of a project. Systems engineers are typically concerned with technical risk and project managers with programmatic risk. Sometimes, technical risk factors are identified and confronted by systems engineers and programmatic risk factors are identified and confronted by project managers without adequate communication between them. In these cases, appropriate tradeoffs among requirements, schedule, budget, infrastructure, and technology may not be made, which creates additional risk for the successful outcome of a project.

In the last ten years, there has been an increasing interest in opportunity management as the converse of risk management. Hillson (2003), Olsson (2007), and Chapman and Ward (2003) provide highly cited introductions.

Additional information on risk management for systems engineering projects can be found in the Risk Management article in Part 3: Systems Engineering and Management.

An Overview of the PMBOK® Guide

- Lead Author:
- Richard Turner
- Contributing Author:
- Alice Squires

-

The *Guide to the Project Management Book of Knowledge (PMBOK® Guide)* is published and maintained by the Project Management Institute (PMI). It is acknowledged as the authoritative documentation of good practices in project management. It is also the basis for certification exams to qualify Project Management Professionals (PMPs). Many organizations require PMP certification as a basic qualification for the role of project manager.

The PMBOK 6th edition and prior editions were organized in a process focus. The PMBOK 7th edition is radically different from the 6th edition, shifting away from a process focus to a principles focus. The 7th edition emphasizes the mindsets, behaviors, and actions of the project manager. The 7th edition is also about a third the length of the 6th edition. This current SEBoK article references the 5th edition. An update is planned to reflect the 6th and 7th editions in a future release of the SEBoK.

Overview

According to Section 1.3 of the *PMBOK® Guide*, project management is *accomplished through the appropriate application and integration of the 47 logically grouped project management processes, which are categorized into five Process Groups* (PMI 2013). The five Process Groups are:

1. Initiating Process Group
2. Planning Process Group
3. Executing Process Group
4. Monitoring and Controlling Process Group
5. Closing Process Group

Each of the 47 processes is specified by Inputs, Tools & Techniques, and Outputs. Data flow diagrams are used in the PMBOK to illustrate the relationships between each process and the other processes in which each process interacts. The processes are also grouped into ten Knowledge Areas. These Knowledge Areas are:

1. Project Integration Management
2. Project Scope Management
3. Project Time Management
4. Project Cost Management
5. Project Quality Management
6. Project Human Resources Management
7. Project Communications Management
8. Project Risk Management
9. Project Procurement Management
10. Project Stakeholder Management

The five process groups are discussed in more detail in the following section.

Initiating Process Group

Activities performed in the **Initiating** process group include: obtaining authorization to start a project; defining the high-level scope of the project; developing and obtaining approval for the project charter; performing key stakeholder analysis; and identifying and documenting high-level risks, assumptions, and constraints. The **Initiating** process group contains two processes: develop the project charter and identify stakeholders.

Planning Process Group

The **Planning** process group consists of 24 processes, including: assessing detailed project requirements, constraints, and assumptions with stakeholders; developing the project management plan; creating the work breakdown structure; developing a project schedule; determining a project budget; and planning for quality management, human resource management, communication management, change and risk management, procurement management, and stakeholder management. The integrated project management plan is presented to key stakeholders.

Executing Process Group

The **Executing** process group includes eight processes that involve performing the work necessary to achieve the stated objectives of the project. Activities include: obtaining and managing project resources; executing the tasks defined in the project plan; implementing approved changes according to the change management plan; performing quality assurance; acquiring, developing, and managing the project team; managing communications; conducting procurements; and managing stakeholder engagement.

Monitoring and Controlling Process Group

The **Monitoring and Controlling** process group is comprised of 11 processes that include: validate and control scope; control schedule; control cost; control quality; control communications; control risks; control procurements; and control stakeholder engagement. Activities include: measuring project performance and using appropriate tools and techniques; managing changes to the project scope, schedule, and costs; ensuring that project deliverables conform to quality standards; updating the risk register and risk response plan; assessing corrective actions on the issues register; and communicating project status to stakeholders.

Closing Process Group

The **Closing** process group involves two processes: closing project or phase and closing procurements. Closing the project or phase involves finalizing all project activities, archiving documents, obtaining acceptance for deliverables, and communicating project closure. Other activities include: transferring ownership of deliverables; obtaining financial, legal, and administrative closure; distributing the final project report; collating lessons learned; archiving project documents and materials; and measuring customer satisfaction.

The scope of project management, as specified in the PMBOK Guide, encompasses the total set of management concerns that contribute to successful project outcomes.

Relationships between Systems Engineering and Project Management

- Lead Author:
- Richard Turner
- Contributing Author:
- Alice Squires

-

This topic discusses the relationship between systems engineering (SE) and project management (PM). As with software engineering, there is a great deal of overlap. Depending on the environment and organization, the two disciplines can be disjoint, partially intersecting, or one can be seen as a subset of the other. While there is no standard relationship, the project manager and the systems engineer encompass the technical and managerial leadership of a project between them, which requires the enterprise of each project manager and system engineer to work out the particular details for their own context.

Overlap

There is a great deal of significant overlap between the scope of systems engineering, as described here (in the SEBoK), CMMI (2011), and other resources and the scope of project management, as described in the *PMBOK® Guide* (PMI 2013), CMMI (2011), and other resources as illustrated in Figure 1.

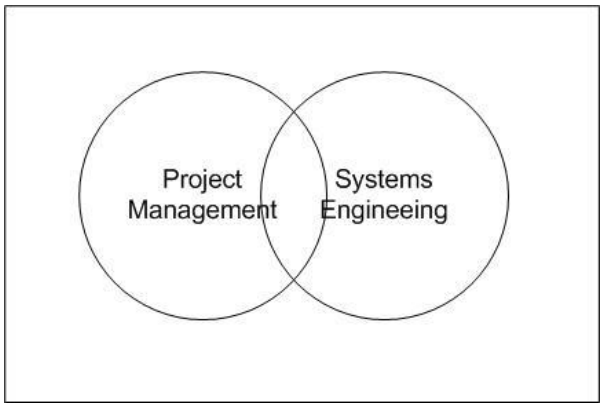

Figure 1. Overlap of PM and SE. (SEBoK Original)

These sources describe the importance of understanding the scope of the work at hand, how to plan for critical activities, how to manage efforts while reducing risk, and how to successfully deliver value to a customer. The systems engineer working on a project will plan, monitor, confront risk, and deliver the technical aspects of the project, while the project manager is concerned with the same kinds of activities for the overall project. Because of these shared concerns, at times there may be confusion and tension between the roles of the project manager and the systems engineer on a given project. As shown in Figure 2, on some projects there is no overlap in responsibility. On other projects, there may be shared responsibilities for planning and managing activities. In some cases, particularly for smaller projects, the project manager may also be the lead technical member of the team performing both roles of project manager and systems engineer.

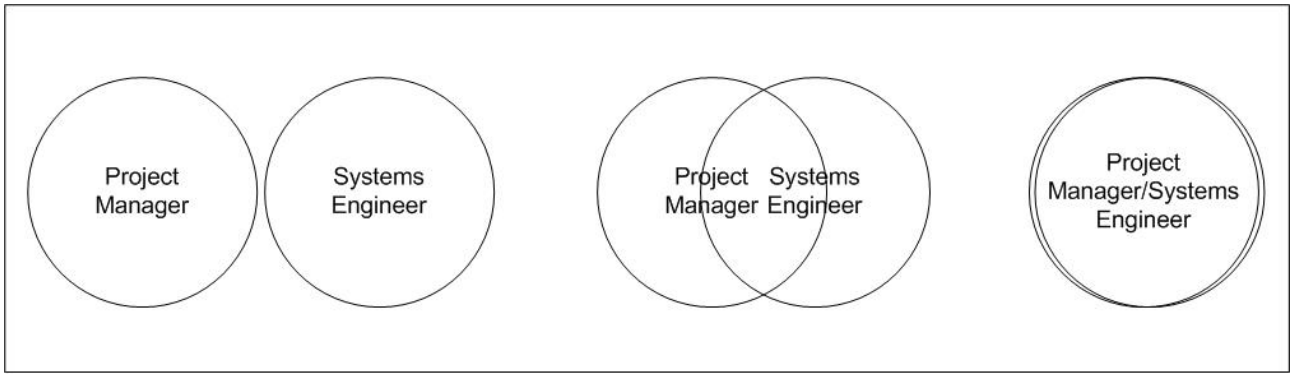

Figure 2. Overlap of Project Roles. (SEBoK Original)

Defining Roles and Responsibilities

Regardless of how the roles are divided up on a given project, the best way to reduce confusion is to explicitly describe the roles and responsibilities of the project manager and the systems engineer, as well as other key team members. The Project Management Plan (PMP) and the Systems Engineering Management Plan (SEMP) are key documents used to define the processes and methodologies the project will employ to build and deliver a product or service.

The PMP is the master planning document for the project. It describes all activities, including technical activities, to be integrated and controlled during the life of the program. The SEMP is the master planning document for the systems engineering technical elements. It defines SE processes and methodologies used on the project and the relationship of SE activities to other project activities. The SEMP must be consistent with and evolve in concert with the PMP. In addition, some customers have technical management plans and expectations that the project's SEMP integrate with customer plans and activities. In the U.S. Department of Defense, most government project teams have a systems engineering plan (SEP) with an expectation that the contractor's SEMP will integrate and remain consistent with customer technical activities. In cases where the project is developing a component of a larger system, the component project's SEMP will need to integrate with the overall project's SEMP.

Given the importance of planning and managing the technical aspects of the project, an effective systems engineer will need to have a strong foundation in management skills and prior experience, as well as possess strong technical depth. From developing and defending basis of estimates, planning and monitoring technical activities, identifying and mitigating technical risk, and identifying and including relevant stakeholders during the life of the project, the systems engineer becomes a key member of the project's management and leadership team. Additional information on Technical Management Processes and Stakeholder Needs Definition can be found in Part 3: Systems Engineering and Management.

Practical Considerations

Effective communication between the project manager and the system engineer is essential for mission accomplishment. This communication needs to be established early and occur frequently.

Resource reallocation, schedule changes, product/system changes and impacts, risk changes: all these and more need to be quickly and clearly discussed between the PM and SE.

The Influence of Project Structure and Governance on Systems Engineering and Project Management Relationships

- Lead Author:
- Alice Squires

-

This article reviews various project structures that impact or provide governance to the project and that require key involvement from the program manager and the systems engineer. These structures include: the structure of the organization itself (functional, project, matrix, and specialized teams, such as Integrated Product Teams (IPTs), Change Control Boards (CCBs), and Engineering Review Boards (ERBs). This article also addresses the influence of schedule-driven versus requirements-driven projects on these structures.

Relationships between Systems Engineering and Project Management are covered in a related article.

An Overview of Project Structures

Project management and systems engineering governance are dependent on the organization's structure. For some projects, systems engineering is subordinated to project management and in other cases, project management provides support to systems engineering. These alternatives are illustrated in Figures 1 and 2 of the Organizing the Team section in Team Capability.

A project exists within the structural model of an organization. Projects are one-time, transient events that are initiated to accomplish a specific purpose and are terminated when the project objectives are achieved. Sometimes, on small projects, the same person accomplishes the work activities of both project management and systems engineering. Because the natures of the work activities are significantly different, it is sometimes more effective to have two persons performing project management and systems engineering, each on a part-time basis. On larger projects there are typically too many tasks to be accomplished for one person to accomplish all of the necessary work. Very large projects may have project management and systems engineering offices with a designated project manager and a designated lead systems engineer.

Projects are typically organized in one of three ways: (1) by functional structure, (2) by project structure, and (3) by a matrix structure (see Systems Engineering Organizational Strategy for a fourth structure and related discussion). In a function-structured organization, workers are grouped by the functions they perform. The systems engineering functions can be: (1) distributed among some of the functional organizations, (2) centralized within one organization or (3) a hybrid, with some of the functions being distributed to the projects, some centralized and some distributed to functional organization. The following figure provides an organizational structure continuum and illustrates levels of governance among the functional organizations and the project.

- In a functional-structured organization, the project manager is a coordinator and typically has only limited control over the systems engineering functions. In this type of organization, the functional manager typically controls the project budget and has authority over the project resources. However, the organization may or may not have a functional unit for systems engineering. In the case where there is a functional unit for systems engineering, systems engineers are assigned across existing projects. Trades can be made among their projects to move the priority of a specific systems engineering project ahead of other projects; thus reducing the nominal schedule for that selected project. However, in the case where there is not a functional unit for systems engineering, the project manager may have to find alternate sources of staffing for systems engineering – for example, hiring systems engineering talent or consultants, promoting or expanding the responsibilities of a current team member, etc.

- In a project-structured organization, the project manager has full authority and responsibility for managing the budget and resources to meet the schedule requirements. The systems engineer is subject to the direction of the project manager. The project manager may work with human resources or a personnel manager or may go outside the organization to staff the project.
- Matrix-structured organization can have the advantages of both the functional and project structures. For a schedule driven project, function specialists are assigned to projects as needed to work for the project manager to apply their expertise on the project. Once they are no longer needed, they are returned to their functional groups (e.g. home office). In a weak matrix, the functional managers have authority to assign workers to projects and project managers must accept the workers assigned to them. In a strong matrix, the project manager controls the project budget and can reject workers from functional groups and hire outside workers if functional groups do not have sufficient available and trained workers.

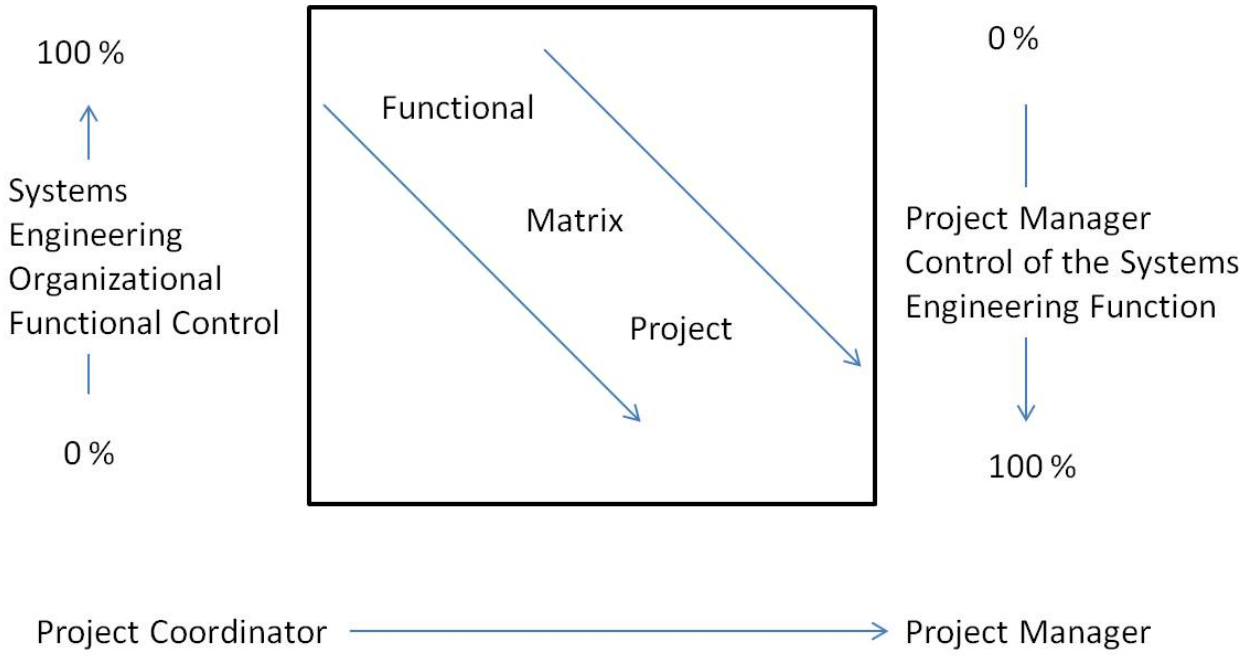

Figure 1. The Organizational Continuum (2). (SEBoK Original and Adapted from Fairley 2009). Reprinted with permission of the IEEE Computer Society. All other rights are reserved by the copyright owner.

In all cases, it is essential that the organizational and governance relationships be clarified and communicated to all project stakeholders and that the project manager and systems engineer work together in a collegial manner.

The Project Management Office (PMO) provides centralized control for a set of projects. The PMO is focused on meeting the business objectives leveraging a set of projects, while the project managers are focused on meeting the objectives of those projects that fall under their purview. PMOs typically manage shared resources and coordinate communication across the projects, provide oversight and manage interdependencies, and drive project-related policies, standards, and processes. The PMO may also provide training and monitor compliance (PMI 2013).

Schedule-Driven versus Requirements-Driven Influences on Structure and Governance

This article addresses the influences on governance relationships between the project manager and the systems engineer. One factor that establishes this relationship is whether a project is schedule-driven or requirements-driven.

In general, a project manager is responsible for delivering an acceptable product/service on the specified delivery date and within the constraints of the specified schedule, budget, resources, and technology.

The systems engineer is responsible for collecting and defining the operational requirements, specifying the systems requirements, developing the system design, coordinating component development teams, integrating the system components as they become available, verifying that the system to be delivered is correct, complete and consistent to its technical specification, and validating the operation of the system in its intended environment.

From a governance perspective, the project manager is often thought of as being a movie producer who is responsible for balancing the schedule, budget, and resource constraints to meet customer satisfaction. The systems engineer is responsible for product content; ergo, the systems engineer is analogous to a movie director.

Organizational structures, discussed previously, provide the project manager and systems engineer with different levels of governance authority. In addition, schedule and requirements constraints can influence governance relationships. A schedule-driven project is one for which meeting the project schedule is more important than satisfying all of the project requirements; in these cases lower priority requirements may not be implemented in order to meet the schedule.

Classic examples of these types of projects are:

- a project that has an external customer with a contractual delivery date and an escalating late delivery penalty, and
- a project for which delivery of the system must meet a major milestone (e.g. a project for an announced product release of a cell phone that is driven by market considerations).

For schedule-driven projects, the project manager is responsible for planning and coordinating the work activities and resources for the project so that the team can accomplish the work in a coordinated manner to meet the schedule. The systems engineer works with the project manager to determine the technical approach that will meet the schedule. An Integrated Master Schedule (IMS) is often used to coordinate the project.

A requirements-driven project is one for which satisfaction of the requirements is more important than the schedule constraint. Classic examples of these types of projects are:

1. exploratory development of a new system that is needed to mitigate a potential threat (e.g. military research project) and
2. projects that must conform to government regulations in order for the delivered system to be safely operated (e.g., aviation and medical device regulations).

An Integrated Master Plan is often used to coordinate event-driven projects.

To satisfy the product requirements, the systems engineer is responsible for making technical decisions and making the appropriate technical trades. When the trade space includes cost, schedule, or resources, the systems engineer interacts with the project manager who is responsible for providing the resources and facilities needed to implement a system that satisfies the technical requirements.

Schedule-driven projects are more likely to have a management structure in which the project manager plays the central role, as depicted in Figure 1 of the Organizing the Team section in Team Capability. Requirement-driven projects are more likely to have a management structure in which the systems engineer plays the central role, as depicted in Figure 2 of the Organizing the Team section in Team Capability.

Along with the Project Management Plan and the Systems Engineering Management Plan, IMP/IMS are critical to this process.

Related Structures

Integrated Product Teams (IPTs), Change Control Boards (CCBs), and Engineering Review Boards (ERBs) are primary examples of project structures that play a significant role in project governance and require coordination between the project manager, systems engineer and other members of the team.

Integrated Product Team

The Integrated Product Team (IPT) ensures open communication flow between the government and industry representatives as well as between the various product groups (see Good Practices in Project Planning). There is typically a top level IPT, sometimes referred to as the Systems Engineering and Integration Team (SEIT) (see Systems Engineering Organizational Strategy), that oversees the lower level IPTs. The SEIT can be led by either the project manager for a specific project or by the systems engineering functional manager or functional lead across many projects. Each IPT consists of representatives from the appropriate management and technical teams that need to collaborate on systems engineering, project management, and other activities to create a high-quality product. These representatives meet regularly to ensure that the technical requirements are understood and properly implemented in the design. Also see Team Capability for more information.

Change Control Board

An effective systems engineering approach includes a disciplined process for change control as part of the larger goal of configuration management. The primary objective of configuration management is to track changes to project artifacts that include software, hardware, plans, requirements, designs, tests, and documentation. Alternatively, a Change Control Board (CCB) with representatives from appropriate areas of the project is set up to effectively analyze, control and manage changes being proposed to the project. The CCB typically receives an Engineering Change Proposal (ECP) from design/development, production, or operations/support and initially reviews the change for feasibility. The ECP may also be an output of the Engineering Review Board (ERB) (see next section). If determined feasible, the CCB ensures there is an acceptable change implementation plan and proper modification and installation procedures to support production and operations.

There may be multiple CCBs in a large project. CCBs may be comprised of members from both the customer and the supplier. As with the IPTs, there can be multiple levels of CCB starting with a top level CCB with CCBs also existing at the subsystem levels. A technical lead typically chairs the CCB; however, the board includes representation from project management since the CCB decisions will have an impact on schedule, budget, and resources.

See Figure 2 under Configuration Management for a flow of the change control process adapted from Blanchard and Fabrycky (2011). See also Capability Updates, Upgrades, and Modernization, and topics included under Enabling Teams. See also the UK West Coast Modernization Project which provides an example where change control was an important success factor.

Engineering Review Board

Another example of a board that requires collaboration between technical and management is the Engineering Review Board (ERB). Examples of ERBs include the Management Safety Review Board (MSRB) (see Safety Engineering). Responsibilities of the ERB may include technical impact analysis of pending change requests (like the CCB), adjudication of results of engineering trade studies, and review of changes to the project baseline. In some cases, the ERB may be the management review board and the CCB may be the technical review board. Alternatively, in a requirement driven organization the ERB may have more influence while in a schedule driven organization the CCB may have more impact.

Cost Estimating and Analysis in Systems Engineering

- Lead Author:
- Gan Wang

-

Cost estimating is a multidisciplinary practice that combines analytical rigor, quantitative analysis, experience, and expert judgment to develop realistic forecasts of future costs. As highlighted in ISO/IEC/IEEE-15288:2023, cost estimating serves diverse purposes across the system life cycle, and is an essential tool for providing stakeholders with insights into resource requirements for system development, acquisition, operations and sustainment. Cost estimating is thus integral to all technical and management processes in systems engineering and project management, and is central to project planning, budgeting, and control, where it is frequently utilized in evaluating trade-offs for analyzing alternative products or services. Cost estimating also plays a pivotal role in the decision-making process for investments and contracting, especially when governmental and/or commercial organizations are involved.

The practice of cost estimating is often considered as a blend of art and science and requires a diverse set of skills and domain expertise, particularly in mathematics, to create a realistic cost forecast for proposed products or services. Historically, cost estimating has been the responsibility of a specialized group of professionals known as cost analysts. However, in recent times, it has increasingly required the involvements and participation of systems engineers to meet the growing demands for deeper product knowledge and system design expertise.

There are established industry best practices and de facto standards. Leading professional associations, including the International Cost Estimating and Analysis Association (ICEAA), with its predecessor, the Society of Cost Estimating and Analysis (SCEA), along with the International Society of Parametric Analysts (ISPA), offer a rich set of references (ICEAA 2024; ISPA 2008; PMI 2021), as well as training courses (ICEAA n.d.; DAU n.d.). Furthermore, different government agencies provide policies and guidelines to communicate requirements and promote best practices (GAO 2020; DoD 2020, 2022; NASA 2015).

This article covers fundamental concepts and key methodologies and processes used in cost estimating and analysis. The goal is to provide a foundational understanding of best practices and to support the seamless integration of these methodologies into systems engineering processes.

Relationship to Systems Engineering and Project Management

Systems engineering is defined as "a transdisciplinary and integrative approach to enable the successful realization, use, and retirement of engineered systems using systems principles and concepts, and scientific, technological, and management methods," according to INCOSE (2021). Integration is the core to systems engineering. It materializes at two different levels.

Firstly, systems engineering integrates the system of interest (SoI) or the prime mission product (PMP) throughout its life cycle, serving as the system design authority from concept definition and design, through development, production, operations, and support. Secondly, systems engineering integrates the project that builds the product, serving as the engineering authority for the project from planning to execution, monitoring, assessment, and control.

Project management involves planning, executing, monitoring and controlling, and closing projects. It encompasses scheduling, resource allocation, risk management, and performance tracking to ensure that the project is completed on time, within budget, and to the specified quality standards.

Cost estimating and analysis is generally considered a practice within the scope of project management, which is a distinctive discipline from systems engineering. However, project management and systems engineering share considerable overlap in scope, especially in the areas of project scope and cost management (INCOSE 2023). The two practices are interdependent and synergistic, particularly in large-scale, complex engineering projects such as those in infrastructure, transportation and mobility, and aerospace and defense systems. In this context, cost estimating plays a crucial role within the project cost management process, underpinning the successful execution and delivery of complex projects.

Furthermore, in practice, engineering cost estimates are generally developed based on the technical scope defined by systems engineers. Cost estimates are heavily influenced by the technical requirements, design complexity, and tasks specified by systems engineering. In other words, systems engineering defines it, cost estimating quantifies it, and project management manages it.

In this context, systems engineers collaborate closely with program or project managers, drawing upon multidisciplinary skills from various fields such as configuration management, information management, risk management, and decision support. Cost estimating and analysis provides a quantitative basis for scope definition, risk management, resource allocation, change management, performance monitoring, tradeoff analysis, and informed decision making. As an integral part of both systems engineering and project management, it ultimately ensures the on-time and on-budget completion of complex projects, ultimately leading to the successful delivery of projects and services.

Definitions

- *Cost estimating*: an exercise to *predict* the future cost of an item, product, program or task, through collecting and analyzing historical data and applying quantitative models, techniques, tools, and databases. The purpose of cost estimating is to translate system and functional requirements associated with programs, projects, proposals or processes into reliable budget requirements. The term *cost estimation* is also used, sometime interchangeably with cost estimating. It typically refers to the act or action of developing a cost estimate, while cost estimating refers to the practice applied to estimation.
- *Cost estimate*: is the *product* of a cost estimating process, which specifies the expected labor effort or dollar cost required to perform a stipulated task, or to acquire a specific item. A cost estimate may constitute a single value or a range of values. A cost estimate can normally be broken down to cost elements.

- *Cost element*: an identifiable function, or a common group of functions, which have been established as a separate entity for the purpose of estimating, collecting, controlling, and reporting costs.
- *Cost driver*: typically a physical or performance attribute of a system, or programmatic parameter of a project or contract, that has the most influence on total estimated cost. A cost driver can be another cost quantity.
- *Cost model*: an analytical tool or framework used to systematically to characterize the behavior of the system or program and produce a credible cost estimate. It implements cost estimating methods (see below).
- *Basis of estimate* (BOE): a document outlining the assumptions, methods, and data used to develop a cost estimate. The BOE explains how the cost estimate is generated and typically includes a detailed description of the work to be performed, the planned approach, the required resources, and the expected schedule or timeline. It is a mandatory component in competitive proposals and formal quotes from potential suppliers to clients.
- *Cost analysis*: a range of activities to review and analyze the estimated or actual costs of a system, a program or a project. It is a comprehensive review of proposed cost estimates or pricing data and includes activities such as sensitivity and what-if analysis that assesses uncertainty or risks associated with the estimates. Relying on the same estimating practice and methodologies, cost analysis can be either retrospective or predictive. Retrospective analysis evaluates the actual costs that have been incurred, while predictive analysis assesses the accuracy and validity of cost estimates before they are finalized. In the United States Department of Defense (DoD) procurement organizations, cost analysis is the evaluation of a contractor's cost and pricing data in order to form an opinion on the degree to which the contractor's proposed costs represent what the performance of the contract should cost, assuming reasonable economy and efficiency.
- *Life Cycle Cost* (LCC): sometimes called Total Cost of Ownership (TCO) or Total Ownership Cost (TOC), LCC is the total cost of acquisition and ownership of a system or capability over its entire life cycle. LCC generally includes the cost of research, development, testing and evaluation (RDT&E), manufacturing and production, operation and support (O&S), and where applicable, dismantle and disposal.

Types of Cost Estimates

Cost estimates are generally categorized based on the purposes they serve. The following are the most common types of cost estimates.

- *Budget estimate*: an estimate developed for the budgeting and funding purposes associated with a program, project, activity, initiative, or operations of an organization, in order to support its objectives consistent with the defined scope, schedule, and resource requirements.
- *Rough order of magnitude (ROM) estimate*: an estimate intended to grossly approximate the expected costs or effort involved in a project, task, or activity. It is often developed in the very early stage of something and with very little specific available information. It is also known as "quick look," initial, or "ballpark" estimate.
- *Firm cost estimate*: an estimate commonly used in cost proposals and intended to be a binding obligation from an offering organization. It relies on well-defined plans and data, usually in response to a customer's firm request for proposal. Firm estimates demand the highest level of substantiating detail, requiring the preparation of an extensive backup package to facilitate contractual fact-finding and negotiations.
- *Life cycle cost (LCC) estimate*: a comprehensive, "cradle to grave" estimate to cover all anticipated expenses from inception to disposal that includes research, development, testing and evaluation (RDT&E), production, operations and support (O&S) and disposal costs. It is typically created to aid the planning and analysis of alternatives for capability acquisition. It is created regardless of funding source and should be done as early in the life cycle as possible. As described above, it may also be referred to as Total Cost of Ownership (TCO) or Total Ownership Cost (TOC) estimate.
- *Should cost (SC) estimate*: an assessment of what it should reasonably cost to produce a product, deliver a service, or execute a project under ideal conditions, assuming efficiency in execution, optimal resource utilization, continuous improvement and cost optimization. It is a management tool typically associated with the acquirer to actively seek cost reduction, drive efficiency, and promote collaboration between buyers and suppliers to achieve

mutual benefits.

- *Estimate at completion (EAC)*: an assessment of the cost to complete the authorized scope of a project based on the historical performance and progress up to a certain point of that project. Often developed at the onset or during the course of the project, it provides an estimate of the total cost expected by the time the project is completed. It is an important *earned value management* (EVM) metric, central to project management.
- *Independent cost evaluation* (ICE): a cost analysis performed by an independent group of experts to assess the reasonableness, accuracy, and completeness of a cost estimate submitted by an offeror. ICE uses the same data provided by the original estimate and involves analyzing and verifying supporting information, such as cost drivers, assumptions, and uncertainties. It typically develops an independent estimate or view, in comparison to the original estimate, and identifies risks and opportunities associated with the program or project.
- *Not-to-exceed (NTE)* and *not-less-than (NLT) estimates*: estimates commonly used in contracting and project management to define the maximum allowable and minimum acceptable costs for the project or contract. These estimates provide basic parameters for managing stakeholder expectations, preparing budgets or proposals, and making informed decisions.

Cost Estimating Process

A cost estimating process generally consists of a seven-step process, as depicted in **Figure 1**. In practice, however, the process may be customized based on factors such as the type of estimate being developed, data availability, and the maturity of developmental stage.

Cost estimating is an iterative process characterized by multiple feedback loops. For instance, data analysis may lead to further questions, necessitating additional data collection. Similarly, validating estimates might involve applying different estimating methods, which could require gathering new data.

Estimates evolve continuously as design matures, development progresses, and more data becomes available. Existing estimate must be refreshed based on updated technical and program management baselines to support major program and project milestones.

Step 1: Develop the Work Breakdown Structure (WBS). The WBS establishes a common frame of reference for relating job tasks to each other and aggregating cost elements at the summary level of detail. It is used to capture the scope of work intended for the estimate. A WBS consists of two parts: a tree-like hierarchical structure defining work elements, and a WBS dictionary, which defines the terms used in the structure. The U.S. DoD developed MIL-STD-881 (DoD 2022) to provide the standard framework and instructions for developing a WBS.

Step 2: Establish a technical baseline. A technical baseline includes all the information required for an estimate, captured at a specific point in time. It includes the technical scope approved for the system under development such as the configuration items, the programmatic scope for the project such as schedule and milestones, as well as the ground rules and assumptions made as the basis for the estimate. While the development continues, the baseline must be frozen for the purpose of estimation.

Step 3: *Collect data*. Data collection involves two kinds of data: the data for the system and program under estimation, and the historical data or database from the like systems and historical projects. They may be collected at the same or different times. The data for estimation is collected from the ongoing system design, necessary in identifying required cost drivers. Collecting historical data is required to apply methodologies and develop or update CERs. As emphasized previously in the methodology section, it is critical to interview key stakeholders, including those from the current and historical programs, which is necessary for understanding of the data collected.

Step 4: *Analyze data*. Collected data must be analyzed to derive useful metrics and enable the application of a cost estimating methodology. Data analysis involves examining collected data to identify useful patterns and gain insights into the appropriate estimating methods to apply to different parts of the estimate. There are commonly deployed tools for data analysis, including scatter plotting, deriving descriptive statistics (e.g., mean, variance, standard deviation), identifying outliers, updating historical database, and calibrating parametric models.

Step 5: *Apply estimating methodology and develop cost estimating relationships*. Select the best estimating method (see Cost Estimating Methodologies section below) based on available data. Establish the *ground rules* and *assumptions* for estimating, as they will dictate how data is used and influence the final outcome of the estimate. Once patterns are identified from data analysis, CERs can be established for different cost elements. This may involve recalibrating or fine-tuning existing CERs to align with the newly collected data or specific project requirements or characteristics. Commercial off-the-shelf estimating models must be calibrated with collected data before being used to generate estimates.

Step 6: *Roll up and validate estimates*. Once the CERs are created, estimated cost or effort can be generated based on the cost driver inputs. When appropriate calibrations, commercial off-the-shelf estimating models may be used produce and summarize the estimate. After the estimates are generated, they must be validated to ensure reasonableness and completeness. Sensitivity analysis and cross-technique validation can be applied to key cost elements. Risk assessment should also be conducted.

Step 7: *Generate cost reports*. Cost report provides a written justification for the cost estimate. This is a formal documentation that captures all aspects of the estimating process and provides sufficient information for a third-party analyst to fully understand how the estimate is developed and to replicate the estimate at a later time, if necessary. In the contracting process, this document is called the *Basis of Estimate* (BOE), which is required to support the bidder's cost proposal.

As indicated previously, cost estimating is always an iterative process. It should be revisited and updated for each major milestone of the development project. There are intermediate feedback loops that may be necessary to complete the process, as shown in **Figure 1**. For example, analysis of data may need additional interviews to fully understand the historical behavior; applying methods and developing CERs may uncover gaps in data, which triggers additional collection efforts.

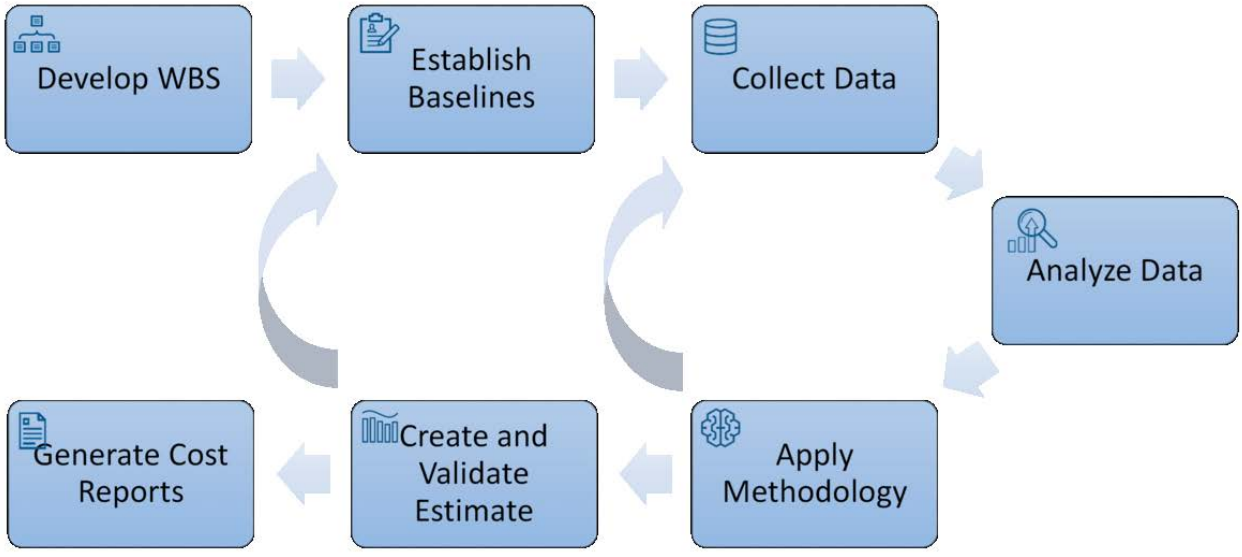

Figure 1. The general cost estimating process. (SEBoK Original)

Cost Estimating Methodologies

Cost estimating methods, also referred to as costing techniques, are the building blocks in developing of a cost estimate. They establish the basic approach to use the historical data and provide the basic structure for statistical relationships. These methods are the basic "algorithms" that relates the historical data to future cost.

Three primary methods are commonly applied when developing a cost estimate (you may hear some other names; but they are mostly synonymous with one of the three methods). These three techniques are *analogy*, *parametric* and *build-up*.

Analogy Method

The *analogy*, also known as *comparative*, method is just what it sounds like – an attempt to estimate costs by comparing the new system with a similar (or analogous) system or by drawing parallels between the current project and a similar past project to estimate costs. It is based on the idea "it's like one of these." An analogy can be done at the system, subsystem, component, project, or task level.

The analogy method is not simply a matter of asserting that an item cost an amount, X, and therefore will cost X in the future. Generally, some adjustments must be made to one or more attributes of the old item to estimate the new item. These quantities for adjustment, known as *cost* or *size drivers*, are typically physical (such as size and weight) and performance (like speed and power) characteristics of a system or service that are the primary drivers for cost or effort. They may also include programmatic metrics such as quantity or schedule, as well as supplier performance or economic adjustments for inflation. For example, suppose the current version of an engine generates 10,000 lbs of thrust and costs $20M dollars to build and that the next-generation version of the same engine is designed to generate 15,000 lbs of thrust. Applying the analogy method, the estimated cost of building the new engine, assuming the use of the same manufacturing technology, would amount to $30M dollars (= 15,000 / 10,000 * $20M). As a second example, if assembly of the current-generation engine initially took 320 person-hours to assemble and unit test 10 equipment racks. Assuming the same process, it is estimated to require 1,600 person-hours (= 50 / 10 * 320 hours) to assemble and unit test 50 racks.

Analogies are generally used in the early stages of the program life cycle, especially when detailed data is lacking but estimates are necessary for decision-making. Many development programs have heritage or legacy systems that can serve as a basis for comparison when estimating costs or efforts for new systems. Additionally, the analogy method can also be used as a validation or crosscheck for estimates created through other methods.

Parametric Method

The *parametric*, also known as *algorithmic*, costing technique is based on mathematical relationships between specific system attributes or parameters (such as weight, thrust, power, lines of code) as one or more independent variables, and the estimated cost or effort of the system as a dependent or derived variable. "This pattern holds" is the fundamental concept underlying this methodology. These parametric relationships are typically expressed as mathematical equations, commonly known as *cost estimating relationships* (CERs), in a general form

The CERs are developed with a statistical framework using historical data collected on similar programs or systems. The independent variables (x, y, …) are known as *cost drivers*. They can be physical characteristics, performance or operational parameters, programmatic variables, or even other costs.

As a hypothetical example, the estimated cost of site activation (C) in $K is a function of the number of workstations (N_{WS}) installed. One identifies a group of similar site activation projects and collects the historical project data. Analysis of the data results in a scatter plot, as shown in **Figure 2**. A CER is derived using linear regression of the scatter data, expressed as a simple equation.

	X (Cost Driver) Number of Workstations	Y Cost ($K)
Site 1	8	$ 398
Site 2	28	$ 769
Site 3	12	$ 430
Site 4	9	$ 199
Site 5	21	$ 447
Site 6	29	$ 851
Site 7	47	$ 1,258
Site 8	7	$ 359
Site 9	36	$ 1,267
Site 10	9	$ 300
Site 11	7	$ 275

b. Scatter plot of activation cost vs. num. workstation, and a linear regression of the data points

Figure 2. Historical site activation data, in tabulated form and scatter plot, and a linear regression of the scatter data points. (SEBoK Original)

The parametric technique is applicable across a wide range of estimates and throughout all phases of the system life cycle. It is often the preferred method for cost proposals, and is frequently favored by source selection authorities. In addition, it is particularly effective in sensitivity analyses, what-if scenarios, and cost-based trade studies, as it allows for the adjustment of system attribute values acting as cost drivers to directly influence the estimated cost or effort.

Most commercial off-the-shelf (COTS) cost estimating tools rely on parametric-based cost models at their core. These algorithms constitute a significant portion of the commercial market value of these tools and are often considered the "secret sauce" provided by the tool vendors.

Build-up Method

The *build-up* method, also known as *detailed* or *bottom-up* estimating, constructs estimates for higher level cost elements by aggregating or “rolling up” detailed estimates from lower level cost elements. It involves estimating costs at the lowest definable level where data exists and summing it up along a hierarchical structure. A *work breakdown structure* (WBS) is generally used to define this hierarchical structure. It provides a standard framework for organizing cost estimates and, therefore, is the cornerstone of this technique.

Based on the idea “it's made up of these,” the build-up method requires breaking down the project into smaller components or work packages and estimating the costs of each individual element. These individual cost estimates are then aggregated to produce the total project cost involves estimating at the lowest definable level where data exists and summing it up along the hierarchical structure. The build-up method works best when low-level detailed cost actuals or estimates are available. It is most effective in operational settings where processes are well-established, and standards and performance factors are clearly defined, enabling effective management of work and measurement of performance.

Other Methods

Two other methods are less rigorous and prevalent, but can be very useful sometimes.

The *expert opinion method*, also known as the *engineering judgment method*, uses an expert or group of experts to estimate the cost of a system. It is often done through one-on-one interviews, round-table discussions with multiple experts, and the Delphi technique, where a group of experts anonymously provides their responses and the results are aggregated.

While expert opinion can offer valuable insights, it is generally considered to be too subjective and prone to biases. Therefore, it should only be utilized as a last resort when other methods are unavailable or to obtain high-level,

low-fidelity estimates for "quick looks." Additionally, it may serve as a cross-check, corroborate objective data, or adjust estimation based on expert insights.

Extrapolation from actual involves using actual costs from past or current items and historic trends to predict future costs for the same item. It is best applied in production settings to estimate the follow-on production units or lots based on the cost of completed units. There are several variants of this method, including *averages*, *learning curves*, and *estimate-at-completion* (EAC). "Extrapolation from actual" is generally not considered a separate method itself, but a subset of other methods, such as *earned value management* (EVM).

Comparison of Techniques

When developing a cost estimate, it is essential to select the most suitable methods for the given task. While it is possible to use multiple techniques within a single estimate, it is crucial to determine how and when each technique should be applied. Just like any other aspect of project management, each technique comes with its own set of strengths and weaknesses and varying degree of applicability for different stages of a program's life cycle. A comparison of the three techniques is provided in **Table 1**.

Figure 3 presents a guideline provided by the Department of Defense (DoD 2022) regarding the typical application of various costing techniques relative to the DoD program lifecycle model. It outlines the approximate distribution of the different techniques across different phases of the DoD acquisition cycle.

Table 1. Comparison of estimating methodologies.

Methodology	Advantage	Disadvantage
Analogy	• Relatively simple, quick, and low cost • Best used early in program before detailed requirements, or as "sanity check" • Difficult to refute if there is strong historical resemblance	• Subjectivity in making adjustments • Difficult to identify common cost drivers between old and new systems for comparison • Lack of objective validity tests • Limited to stable technology and processes
Parametric	• Relatively simple, quick, and low cost • Easily adjusted for changes by modifying input parameters • Best for sensitivity and impact analyses • Effective for cost-based trade studies • Objective measures of validity • Preferred by cost analysts	• Highly dependent upon quantity and quality of historical database • Expensive to collect and maintain historical database • Must continue to update relationships to adjust for updates in relevant programs, processes, and technologies applied • "Black box syndrome" with pre-existing CERs and commercial models
Build-Up	• Most detailed technique and data, and best inherent accuracy • Easy to see exactly what the estimate includes and contribution of cost elements • Variance factors based on historical data for a given program or a specific manufacturer • Typical required to support organizational cost and pricing proposal	• Expensive and time consuming to develop • Requires large amount of data to be collected, maintained, and analyzed • Detailed specifications and definitions required • May underestimate system integration and other "under the line" system level cost • Small errors can easily magnify • Omissions and duplications are likely

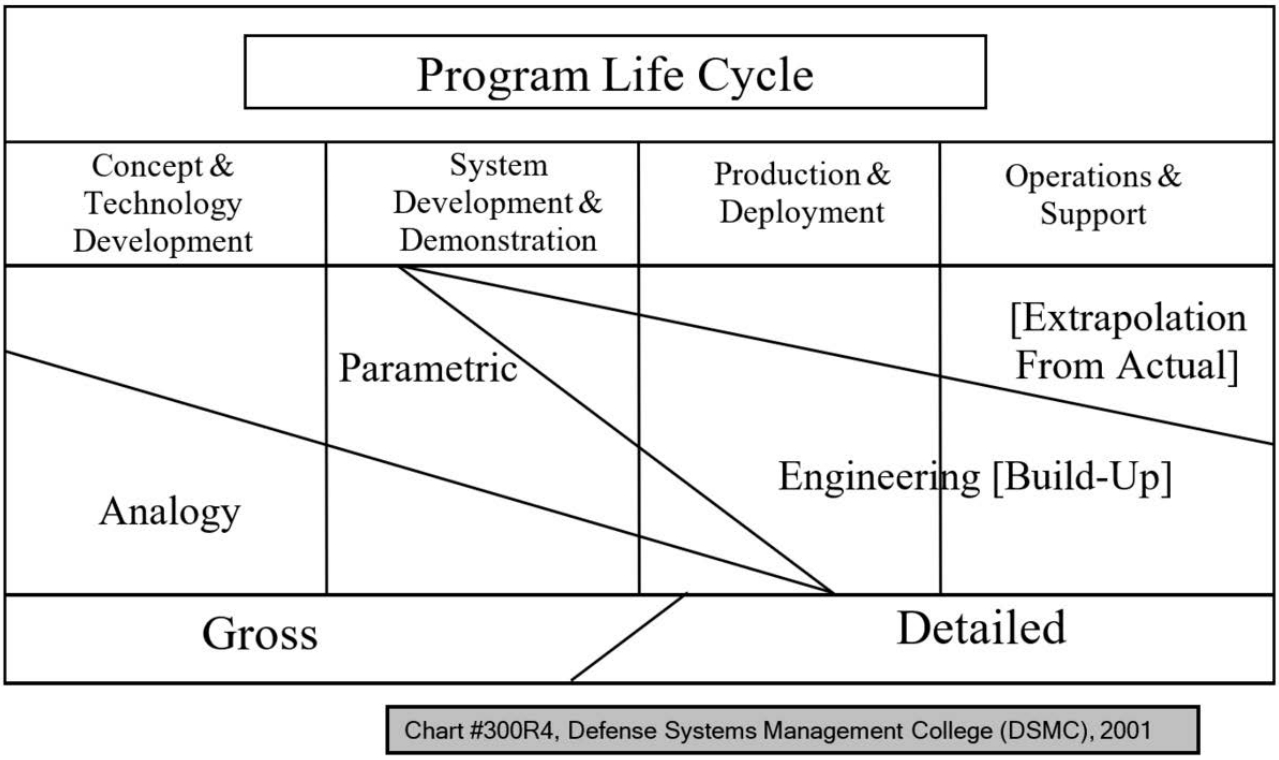

Figure 3. Application of methodologies relative to DoD program phase lifecycle model. (Public Domain, Defense Acquisition University. Used with permission.)

The Role of Historical Data

Data, particularly historical data, is the very foundation for cost estimating. Without it, there is no basis for applying methodologies, and the estimates lack both credibility and defensibility. In essence, without data, there can be no cost estimation, and any estimates made without sufficient data would be nothing more than mere guesses.

Collecting historical data is akin to forensic analysis of the development history, and it is typically done as a separate effort before estimation is required or as part of continuous enterprise knowledge management and process improvement efforts. It can be considered a project in its own right, requiring dedicated resources and tools, as well as access to both technical and financial data. An important aspect of historical data collection is stakeholder interviews, or the ability to speak to the system design and project management authorities of the historical programs, in order to enable understanding of the data collected.

Conclusion

Cost estimating is a multidisciplinary practice that develops future costs for products and services by analyzing historical data and using quantitative methods. It falls in the intersecting areas of systems engineering and project management and demands a wide range of skills and expertise, particularly in mathematics. Effective cost estimating relies on collaboration between systems engineers and cost analysts. This practice is crucial for decision-making, especially in areas involving resource allocation and investment planning.

Procurement and Acquisition

- Lead Author:
- Dick Fairley
- Contributing Author:
- Alice Squires

-

Procurement is the act of buying goods and services. Acquisition covers the conceptualization, initiation, design, development, testing, contracting, production, deployment, logistics support, modification, and disposal of weapons and other systems, as well as supplies or services (including construction) to satisfy organizational needs intended for use in, or in support of, defined missions (DAU 2010; DoD 2001).

Acquisition covers a much broader range of topics than procurement. Acquisition spans the whole life cycle of acquired systems. The procurement of appropriate systems engineering (SE) acquisition activities and levels of SE support is critical for an organization to meet the challenge of developing and maintaining complex systems.

The *Guide for Integrating Systems Engineering into DoD Acquisition Contracts* addresses how systems engineering activities are integrated into the various elements of acquisition and procurement (DoD 2006a).

Acquisition Process Model

Multiple acquisition process models exist. An acquisition process for major systems in industry and defense is shown in Figure 1. The process of acquisition is defined by a series of phases during which technology is defined and matured into viable concepts. These concepts are subsequently developed and readied for production, after which the systems produced are supported in the field.

Acquisition planning is the process of identifying and describing needs, capabilities, and requirements, as well as determining the best method for meeting those requirements (e.g., program acquisition strategy). This process includes procurement; thus, procurement is directly linked to the acquisition process model. The process model present in Figure 1 allows a given acquisition to enter the process at any of the development phases.

For example, a system using unproven technology would enter at the beginning stages of the process and would proceed through a lengthy period of technology maturation. On the other hand, a system based on mature and proven technologies might enter directly into engineering development or sometimes even production.

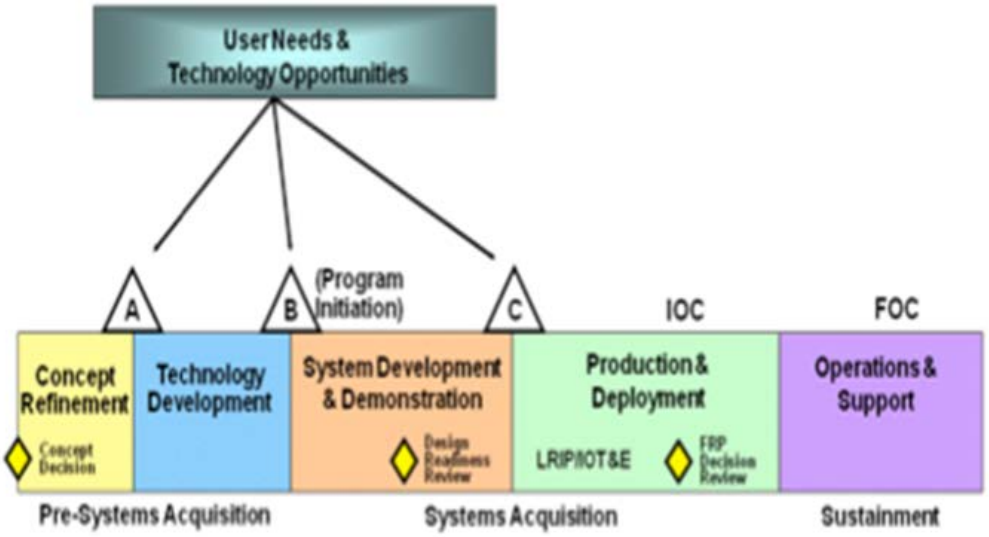

Figure 1. An Acquisition Process Model (DAU 2010). Released by Defense Acquisition University (DAU)/U.S. Department of Defense (DoD).

Systems Engineering Role in the Acquisition Process

The procurement of complex systems usually requires a close relationship between the offeror and supplier SE teams due to the breadth and depth of SE activities. SE is an overarching process that the program team applies in order to transition from a stated capability need to an affordable, operationally effective, and suitable system.

SE is important to every phase of the acquisition process. SE encompasses the application of SE processes across the acquisition life cycle and is intended to be an integrating mechanism for balanced solutions addressing capability needs, design considerations, and constraints. It is also intended to address limitations imposed by technology, budget, and schedule.

SE is an interdisciplinary approach; that is, it is a structured, disciplined, and documented technical effort to simultaneously design and develop system products and processes to satisfy the needs of the customer. Regardless of the scope and type of program, or at what point it enters the program acquisition life cycle, the technical approach to the program needs to be integrated with the acquisition strategy to obtain the best program solution.

Acquisition and procurement in the commercial sector have many characteristics in common with their counterparts in the realm of government contracting, although the processes in the commercial world are usually accomplished with fewer rigors than occur between government and contractor interactions. Offshore outsourcing is commonly practiced in the commercial software arena with the goal of reducing the cost of labor. Commercial organizations sometimes subcontract with other commercial organizations to provide missing expertise and to balance the ebb and flow of staffing needs.

In some cases, relations between the contracting organization and the subcontractor are strained because of the contracting organization's desire to protect its intellectual property and development practices from potential exposure to the subcontractor. Commercial organizations often have lists of approved vendors that are used to expedite the procurement of needed equipment, products, and services. In these situations, commercial organizations have processes to evaluate and approve vendors in ways that are analogous to the qualification of government contractors. Many commercial organizations apply SE principles and procedures even though they may not identify the personnel and job functions as "systems engineers" or "systems engineering."

Importance of the Acquisition Strategy in the Procurement Process

The acquisition strategy is usually developed during the front end of the acquisition life cycle. (For an example of this, see the Technology Development Phase in Figure 1.) The acquisition strategy provides the integrated strategy for all aspects of the acquisition program throughout the program life cycle.

In essence, the acquisition strategy is a high-level business and technical management approach designed to achieve program objectives within specified resource constraints. It acts as the framework for planning, organizing, staffing, controlling, and leading a program, as well as for establishing the appropriate contract mechanisms. It provides a master schedule for research, development, testing, production, fielding, and other SE related activities essential for program success, as well as for formulating functional strategies and plans.

The offeror's program team, including systems engineering, is responsible for developing and documenting the acquisition strategy, which conveys the program objectives, direction, and means of control based on the integration of strategic, technical, and resource concerns. A primary goal of the acquisition strategy is the development of a plan that will minimize the time and cost of satisfying an identified, validated need while remaining consistent with common sense and sound business practices. While the contract officer (CO) is responsible for all contracting aspects, including determining which type of contract is most appropriate, and following the requirements of existing regulations, directives, instructions, and policy memos of an organization, the program manager (PM) works with the CO to develop the best contract/procurement strategy and contract types.

Relating Acquisition to Request for Proposal and Technical Attributes

There are several formats for requesting proposals from offerors for building complex systems. Figure 2 relates acquisition program elements to a representative request for proposal (RFP) topical outline and key program technical attributes that have been used by the Department of Defense. In general, programs have a better chance of success when both the offeror and supplier understand the technical nature of the program and the need for the associated SE activities.

The offeror and supplier need to clearly communicate the technical aspect of the program throughout the procurement process. The offeror's RFP and the associated supplier proposal represent one of the formal communications paths. A partial list of key program technical attributes is presented in Figure 2.

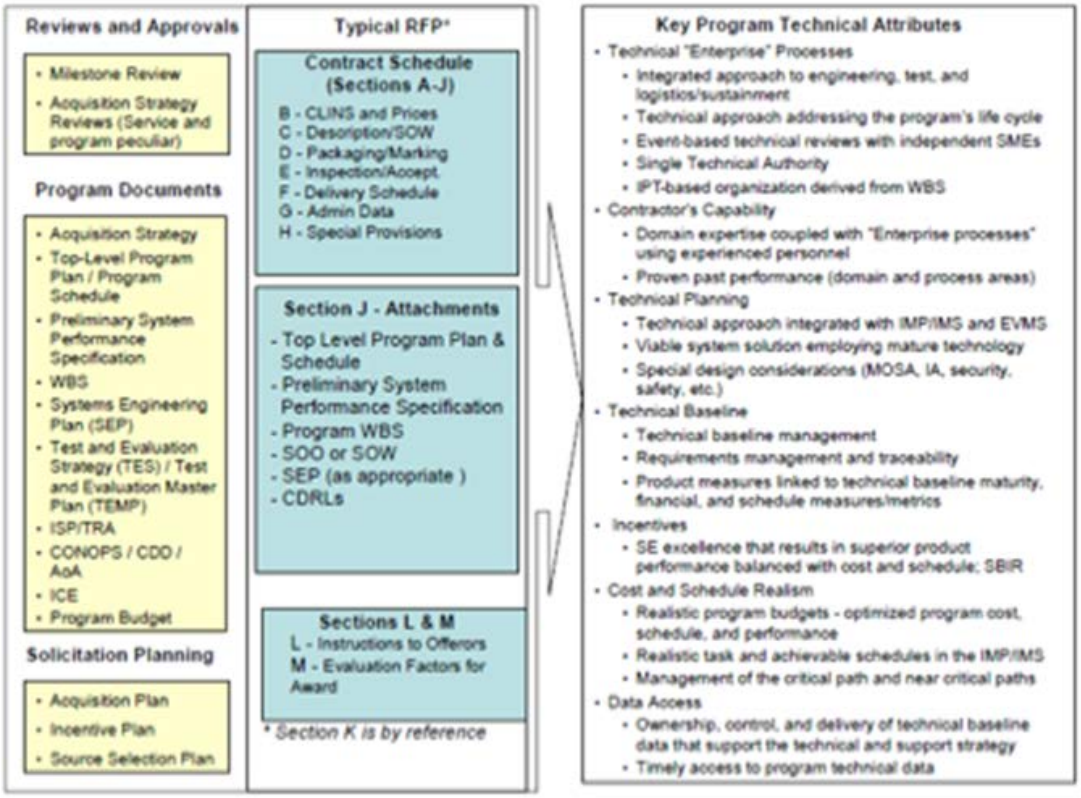

Figure 2. Relating Acquisition to Request for Proposal and Technical Attributes. (DoD 2006a). Released by the U.S. Office of the Secretary of Defense.

Contract-Related Activities and the Offeror's Systems Engineering and Project Management Roles

A clear understanding of the technical requirements is enhanced via the development of a Systems Engineering Plan (SEP). The SEP documents the systems engineering strategy for a project or program and acts as the blueprint for the conduct, management, and control of the technical aspects of the acquisition program (DoD 2011). The SEP documents the SE structure and addresses government and contractor boundaries. It summarizes the program's selected acquisition strategy and identifies and links to program risks. It also describes how the contractor's, and sometimes the subcontractor's and suppliers', technical efforts are to be managed.

Once the technical requirements are understood, a contract may be developed and followed by the solicitation of suppliers. The offeror's PM, chief or lead systems engineer, and CO must work together to translate the program's acquisition strategy and associated technical approach (usually defined in a SEP) into a cohesive, executable contract(s).

Table 1 shows some key contracting-related tasks with indicators of the roles of the PM and LSE.

Table 1. Offeror's Systems Engineering and Program Management Roles (DoD 2006). Released by the U.S. Office of the Secretary of Defense.

Typical Contract-Related Activities	Systems Engineer and Project Manager Roles
1. Identify overall procurement requirements and associated budget. Describe the offer's needs and any constraints on the procurement.	1. Lead systems engineer (LSE) provides program technical requirements. PM provides any programmatic related requirements.
2. Identify technical actions required to successfully complete technical and procurement milestones. The program's SEP is the key source for capturing this technical planning.	2. LSE defines the technical strategy/approach and required technical efforts. This should be consistent with the program's Acquisition Strategy.
3. Document market research results and identify potential industry sources.	3. PM and LSE identify programmatic and technical information needed and assist in evaluating the results.
4. Prepare a Purchase Request, including product descriptions; priorities, allocations and allotments; architecture; government-furnished property or equipment (or Government-Off-The-Shelf (GOTS); government-furnished information; information assurance and security considerations; and required delivery schedules.	4. PM and LSE ensure the specific programmatic and technical needs are defined clearly (e.g., commercial-off-the-shelf (COTS) products).
5. Identify acquisition streamlining approach and requirements, budgeting and funding, management information requirements, environmental considerations, offeror's expected skill sets, and milestones. These should be addressed in the Acquisition Strategy.	5. The procurement team work together, but the CO has the prime responsibility. The PM is the owner of the program Acquisition Strategy. The LSE develops and reviews (and the PM approves) the technical strategy.
6. Plan the requirements for the contract Statement of Objectives (SOO) / Statement of Work (SOW) / specification, project technical reviews, acceptance requirements, and schedule.	6. LSE is responsible for the development of the technical aspects of the SOO/SOW.
7. Plan and conduct Industry Days as appropriate.	7. PM and LSE support the CO in planning the meeting agenda to ensure technical needs are discussed.
8. Establish contract cost, schedule, and performance reporting requirements. Determine an incentive strategy and appropriate mechanism (e.g., Award Fee Plan and criteria).	8. LSE provides technical resource estimates. LSE supports development of the Work Breakdown Structure (WBS) based on preliminary system specifications, determines event-driven criteria for key technical reviews, and determines what technical artifacts are baselined. The PM and LSE advise the CO in developing the metrics/criteria for an incentive mechanism.
9. Identify data requirements.	9. LSE identifies all technical Contractor Data Requirements List (CDRL) and technical performance expectations.
10. Establish warranty requirements, if applicable.	10. LSE works with the CO to determine cost-effective warranty requirements.
11. Prepare a Source Selection Plan (SSP) and RFP (for competitive contracts).	11. PM and LSE provide input to the SSP per the SOO/SOW.
12. Conduct source selection and award the contract to the successful offeror.	12. PM and LSE participate on evaluation teams.

Offeror and Supplier Interactions

There should be an environment of open communication prior to the formal source selection process. This ensures that the supplier understands the offeror's requirements and that the offeror understands the supplier's capabilities and limitations, as well as enhancing the supplier's involvement in the development of a program acquisition strategy. During the pre-solicitation phase, the offeror develops the solicitation and may ask suppliers to provide important insights into the technical challenges, program technical approach, and key business motivations.

For example, potential bidders could be asked for their assessment of a proposed system's performance based on the maturity level of new and existing technologies.

Contracts and Subcontracts

Typical types of contracts include the following:

- **Fixed Price**: In a fixed price contract the offeror proposes a single price for all products and services to implement the project. This single price is sometimes referred to as low bid or lump sum. A fixed price contract transfers the project risks to the supplier. When there is a cost overrun, the supplier absorbs it. If the supplier performs better than planned, their profit is higher. Since all risks are absorbed by the supplier, a fixed price bid may be higher to reflect this.
- **Cost-reimbursement** [Cost plus]: In a cost-reimbursement contract the offeror provides a fixed fee, but also reimburses the contractor for labor, material, overhead, and administration costs. Cost-reimbursement type contracts are used when there is a high level of project risk and uncertainty. With this type of contract, the risks reside primarily with the offeror. The supplier gets reimbursed for all of its costs. Additional costs that arise due to changes or rework are covered by the offeror. This type of contract is often recommended for the system definition of hardware and software development when there is a risk of stakeholder changes to the system.
- **Subcontracts**: A subcontractor performs work for another company as part of a larger project. A subcontractor is hired by a general contractor (also known as a prime or main contractor) to perform a specific set of tasks as part of the overall project. The incentive to hire subcontractors is either to reduce costs or to mitigate project risks. The systems engineering team is involved in establishing the technical contract requirements, technical selection criteria, acceptance requirements, and the technical monitoring and control processes.
- **Outsource contracts**: Outsourced contracts are used to obtain goods or services by contracting with an outside supplier. Outsourcing usually involves contracting a business function, such as software design and code development, to an external provider.
- **Exclusively Commercial Off-the-Shelf (COTS)**: Exclusively COTS contracts are completely satisfied with commercial solutions that require no modification for use. COTS solutions are used in the environment without modifying the COTS system. They are integrated into an existing user's platform or integrated into an existing operational environment. The systems engineering team is involved in establishing the technical contract requirements, technical acceptance, and technical selection criteria.
- **Integrated COTS**: Integrated COTS contracts use commercially available products and integrate them into existing user platforms or operational environments. In some cases, integrated COTS solutions modify the system's solution. The cost of integrating the commercial COTS product into the operational environment can exceed the cost of the COTS product itself. As a result, the systems engineering team is usually involved in establishing the technical outsourcing contract requirements, technical selection criteria, technical monitoring and control processes, and technical acceptance and integration processes.
- **COTS Modification**: COTS modification requires the most time and cost because of the additional work needed to modify the COTS product and integrate it into the system. Depending on how complex and critical the need is, the systems engineering team is usually involved in establishing the technical outsource contract requirements, technical selection criteria, technical monitoring and control processes, and technical acceptance requirements.
- **IT services**: IT services provide capabilities that can enable an enterprise, application, or Web service solution. IT services can be provided by an outsourced service provider. In many cases, the user interface for these Web services is as simple as a Web browser. Depending on how complex and critical the needs are, the systems engineering team can be involved in establishing the technical outsourcing contract requirements, technical selection criteria, and technical acceptance process.

Portfolio Management

- Lead Authors:
- Eric Specking, Gregory S. Parnell, and Ed Pohl

-

Systems engineers need to be aware of and understand the role of systems engineering in project, program, and portfolio management (PfM) processes to achieve maximum stakeholder value. In general, program and project management practices help ensure that organizations execute programs and projects the "right" way. Portfolio management can help to ensure they select the "right" programs and projects, and systems engineering ensures they use the "right" systems thinking (Specking et al. 2020). Not using portfolio management practices increases organizational risk and could decrease stakeholder value.

This article provides:

- a description of the ISO/IEC/IEEE 15288 activities and tasks with regards to portfolio management;
- a description of the Project Management Institute's (PMI's) portfolio life cycle process based on PMI's Guide to the Project Management Body of Knowledge (PMI 2017a);
- the connection of the PMI's portfolio life cycle process to ISO/IEC/IEEE 15288;
- a reference to the principles of portfolio management from the PfM Standard;
- a realignment of the SE Handbook's common approaches/tips with the PfM Standard's six domains;
- a discussion to better clarify systems engineering's relationship to portfolio management, as well as systems engineering's relationship to other topics, such as project management and program management; and
- a description of the systems engineer's role to support portfolio managers that explicitly states how a systems engineer (a) helps evaluate the value of projects to authorize, continue, or terminate enterprise projects and (b) manages their portfolio of systems engineering activities to support portfolio managers and to support enterprise processes, products, and services.

Portfolio Management Overview

ISO/IEC/IEEE 15288 (ISO/IEC/IEEE 2015) establishes portfolio management's importance to systems engineering by including it as an organizational project-enabling process. This organizational project-enabling process uses an organization's strategic plan, portfolio direction and constraints, supply strategy, and project status report as inputs, while a portfolio management plan, organization infrastructure needs, project direction, project portfolio, organization lessons learned, portfolio management report, and portfolio management records are outputs (INCOSE 2015). Portfolio management uses these inputs to perform processes that help enterprises define and authorize projects; evaluate the portfolio of projects and programs; and terminate projects to develop the portfolio management outputs. These activities take place throughout the portfolio life cycle, which includes optimization, initiation, planning, and execution (PMI 2017b).

Portfolio Management Process Implementation

The proper implementation of portfolio management processes results in seven major portfolio management outcomes: 1) qualification and prioritization of business venture opportunities, investments, or necessities; 2) identification of projects; 3) allocation of project resources and budgets; 4) description of project management responsibilities, accountability, and authorities; 5) sustainment of project meeting agreement and stakeholder requirements; 6) redirection or termination of unsatisfactory projects; and 7) closure of successfully completed projects (ISO/IEC/IEEE, 2015). A project should continue if it contributes to organizational strategy; makes progress on achieving its pre-established goals; obeys organizational project directives; is executed according to its pre-approved plan; and continues to add value to the organization with acceptable returns (INCOSE 2015).

Organizations can increase portfolio value by successfully implementing portfolio management processes through six performance management domains throughout the portfolio life cycle (PMI 2017b). These domains, described in Table 1, include portfolio strategic management, portfolio governance, portfolio capacity and capability management, portfolio stakeholder engagement, portfolio value management, and portfolio risk management.

Table 1. Performance Management Domain Descriptions for Portfolio Management (Specking et al. 2020)

Domain	Description
Portfolio Strategic Management	Align portfolio components to one or more strategic objectives and monitor impact
Portfolio Governance	"Through open and transparent governance, including processes for categorizing, prioritizing, selecting, and approving portfolio components, key stakeholders are more likely to accept the decisions and agree with the process, even when they may not fully endorse the decisions made" (PMI 2017b).
Portfolio Capacity and Capability Management	"The selection of portfolio components and the roadmap for their implementation is balanced against the organization's current capacity and capability with the potential of bringing in additional resources" (PMI 2017b).
Portfolio Stakeholder Engagement	"Key portfolio stakeholders require active expectation management" (PMI 2017b).
Portfolio Value Management	Use the organizational strategy to enable investment in a portfolio with the expectation of a pre-determined return
Portfolio Risk Management	Evaluate risk (positive/opportunities, negative/threats) and consider how those risks might impact accomplishing the portfolio strategic plan and objectives

These domains use some or all of the seven PMI fundamental principles for portfolio management (PMI 2017b). The seven PMI fundamental principles for portfolio management include:

- *Strive to achieve excellence in strategic execution;*
- *Enhance transparency, responsibility, accountability, sustainability, and fairness;*
- *Balance portfolio value against overall risks;*
- *Ensure that investments in portfolio components are aligned with the organization's strategy;*
- *Obtain and maintain the sponsorship and engagement of senior management and key stakeholders;*
- *Exercise active and decisive leadership for the optimization of resource utilization;*
- *Foster a culture that embraces change and risk; and*
- *Navigate complexity to enable successful outcomes.*

Portfolio Management Process Best Practices

INCOSE's Systems Engineering Handbook (INCOSE 2015) provides several best practices for performing portfolio management processes. These best practices connect to one or more of the six performance management domains seen in Table 2.

Table 2. SE Handbook Best Practices for Portfolio Management (Modified from (Specking et al. 2020))

Performance Management Domain for Portfolio Management	Key Word for Best Practice	Description of Best Practices
• Portfolio Strategic Management • Portfolio Strategic Engagement • Portfolio Value Management	Right Stakeholders	Include relevant stakeholders when developing the organization's business area plan to enable the organization to determine present and future strategic objectives for focusing resources
• Portfolio Value Management • Portfolio Governance	Measurable Criteria	Prioritize opportunities based upon measurable criteria that contains a stated threshold of acceptable performance
• Portfolio Value Management • Portfolio Governance • Portfolio Capacity and Capability Management	Progress Assessment	Base expected project outcomes on defined, measurable criteria with specific investment assessment information to enable an impartial progress assessment
• Portfolio Governance	Coordinate Interactions	Use some type of coordination organization, such as a program office, to manage the interactions among active projects
• Portfolio Governance	Consider Products and Systems	Use a product line approach for scenarios where multiple customers need the same/similar system but customize the system as necessary
• Portfolio Risk Management	Assess Risk	Assess risk during current project evaluation and cancel/suspend projects with risks that outweigh the investment
• Portfolio Strategic Management • Portfolio Capacity and Capability Management	Align with Strategy	Perform opportunity assessments of ongoing projects and avoid opportunities that contain unacceptable levels of risks, resource demands, or uncertainties or does not aligned with organization capabilities, strategic goals, or strategic objectives
• Portfolio Value Management • Portfolio Governance	Allocate Resources	Allocate resources based upon project requirements
• Portfolio Governance	Effective Governance	Use effective governance processes, which support investment decision making and project management communications

Relationships Between Systems Engineering, Portfolio Management, and Project Management

It is often difficult for systems engineers to understand the relationships between systems engineering, portfolio management, and project management because of their overlapping processes and the use of similar tools. Figure 1 shows the role of project management, systems engineering, and portfolio management for developing and improving an enterprise architecture to provide products or services to many stakeholders. Project and program managers and systems engineers all interact with stakeholders and the enterprise architecture, which consists of products or services and the systems that make them. Systems engineers use the enterprise architecture to develop user and system functional hierarchies, which enable capability development. These capabilities help systems engineers evaluate the enterprise's current and future states. From this evaluation, the Project Management Office (portfolio managers) can develop a potential list of projects or programs to fund. Portfolio managers use best practices in decision analysis (Parnell et al. 2013) to develop a project prioritization value model (e.g. single or multiple objective decision analysis model). Portfolio managers then use optimization techniques to determine which projects or programs to fund based upon the prioritization value model. Project managers then execute the funded projects to ensure that the projects stay on schedule and within budget constraints while meeting desired performance metrics. Information impacting systems engineering documentation discovered from the funded

projects updates the functional hierarchies and system architecture. Throughout the project, portfolio managers receive updates from project managers on project progress. Portfolio managers use progress information to evaluate the project for continuation or termination. If the project is terminated upon successful completion of the project, the project's outcomes update the enterprises' architecture. Otherwise (i.e. terminated early or upon an unsuccessful completion), portfolio managers update their list of potential projects and/or programs for reprioritization. This cycle continues and evolves with time based upon the enterprise's strategy.

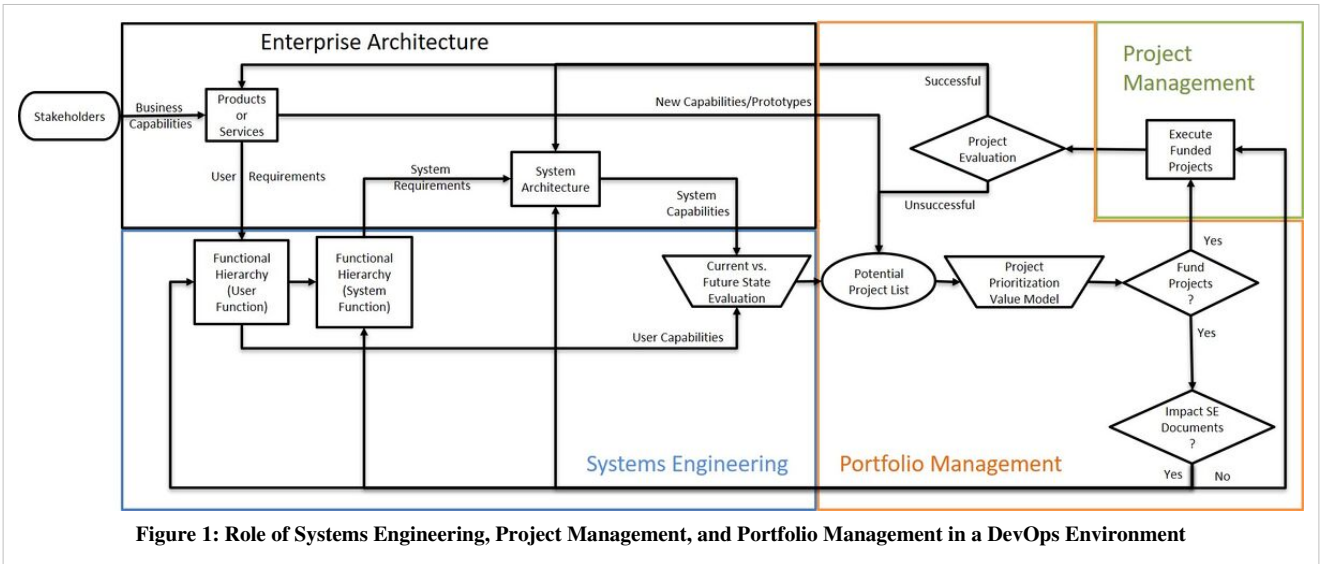

Figure 1: Role of Systems Engineering, Project Management, and Portfolio Management in a DevOps Environment

In addition to helping systems engineers understand the roles of systems engineering, portfolio management, and project management, Figure 1 provides insights into the relationships between the processes from an enterprise DevOps environment perspective.

Software is prominent in most modern systems architectures and is often the primary means for integrating complex system components. Software engineering and systems engineering are not merely related disciplines; they are intimately intertwined. (See Systems Engineering and Other Disciplines.) Good systems engineering is a key factor in enabling good software engineering.

The SEBoK explicitly recognizes and embraces the intertwining between systems engineering and software engineering, as well as defining the relationship between the SEBoK and the Guide to the Software Engineering Body of Knowledge (SWEBOK) (Bourque, and Fairley 2014; IEEE Computer Society 2022).

This knowledge area describes the nature of software, provides an overview of the SWEBOK, describes the concepts that are shared by systems engineers and software engineers, and indicates the similarities and difference in how software engineers and systems engineers apply these concepts and use common terminology. It also describes the nature of the relationships between software engineering and systems engineering and describes some of the methods, models and tools used by software engineers.

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs, in turn, are divided into topics. This KA contains the following topics:

- Software Engineering in the Systems Engineering Life Cycle
- The Nature of Software
- An Overview of the SWEBOK Guide
- Key Points a Systems Engineer Needs to Know about Software Engineering
- Software Engineering Features - Models, Methods, Tools, Standards, and Metrics

Discussion

Software engineers, like systems engineers:

- engage in analysis and design, allocation of requirements, oversight of component development, component integration, verification and validation, life cycle sustainment, and system retirement.
- work with or as a component specialist (for example, user interface, database, computation, and communication specialists) who construct or otherwise obtain the needed software components.
- adapt existing components and incorporate components supplied by customers and affiliated organizations.

These commonalities would make it appear that software engineering is merely an application of systems engineering, but this is only a superficial appearance. The differences between the two disciplines arise from two fundamental concerns:

1. Differences in educational backgrounds (traditional engineering disciplines for SE and the computing disciplines for SWE) and work experiences that result in different approaches to problem solving, and
2. Different ways of applying shared concepts based on the contrasting natures of the software medium and the physical media of traditional engineering.

Table 1 itemizes some of the shared concepts that are applied in different ways by systems engineers and software engineers. Each discipline has made contributions to the other. Table 1 indicates the methods and techniques developed by systems engineers adapted for use by software engineers and, conversely, those that have been adapted for use by systems engineers.

Table 1. Adaptation of Methods Across SE and SWE (Fairley and Willshire 2011) Reprinted with permission of Dick Fairley and Mary Jane Willshire. All other rights are reserved by the copyright owner. *

Systems Engineering Methods Adapted to Software Engineering	Software Engineering Methods Adapted to Systems Engineering
• Stakeholder Analysis	• Model-Driven Development
• Requirements Engineering	• UML-SysML
• Functional Decomposition	• Use Cases
• Design Constraints	• Object-Oriented Design
• Architectural Design	• Iterative Development
• Design Criteria	• Agile Methods
• Design Tradeoffs	• Continuous Integration
• Interface Specification	• Process Modeling
• Traceability	• Process Improvement
• Configuration Management	• Incremental Verification and Validation
• Systematic Verification and Validation	

The articles in this knowledge area give an overview of software and software engineering aimed at systems engineers. It also provides more details on the relationship between systems and software life cycles and some of the detailed tools used by software engineers. As systems become more dependent on software as a primary means of delivering stakeholder value, the historical distinction between software and systems engineering may need to be challenged. This is a current area of joint discussion between the two communities which will affect the future knowledge in both SEBoK and SWEBoK.

Software Engineering in the Systems Engineering Life Cycle

- Lead Authors:
- Tom Hilburn and Dick Fairley
- Contributing Author:
- Alice Squires

-

This article describes how software engineering (SwE) life cycle processes integrate with the SE life cycle. A joint workshop organized by INCOSE, the Systems Engineering Research Center and the IEEE Computer Society was held to consider this relationship (Pyster et al. 2015). This workshop concluded that:

> *Software is fundamental to the performance, features, and value of most modern engineering systems. It is not merely part of the system, but often shapes the system architecture; drives much of its complexity and emergent behavior; strains its verification; and drives much of the cost and schedule of its development. Given how significant an impact software has on system development and given how complex modern systems are, one would expect the relationship between the disciplines of systems engineering (SE) and software engineering (SWE) to be well defined. However, the relationship is, in fact, not well understood or articulated.*

In this article we give some of the basic relationships between SwE and SE and discuss how these can be related to some of the SEBoK knowledge areas.

Systems Engineering and Software Engineering Life Cycles

The Guide to the Software Engineering Body of Knowledge (SWEBoK) (Bourque and Fairley, 2014) describes the life cycle of a software product as:

- analysis and design,
- construction,
- testing,
- operation,
- maintenance, and eventually
- retirement or replacement.

This life cycle is common to most other mature engineering disciplines.

In Part 3 of the SEBoK, SE and Management, there is a discussion of SE life cycle models and life cycle processes. A Generic Life Cycle Model is described and reproduced in Fig. 1 below. This is used to describe necessary stages in the life cycle of a typical engineered system.

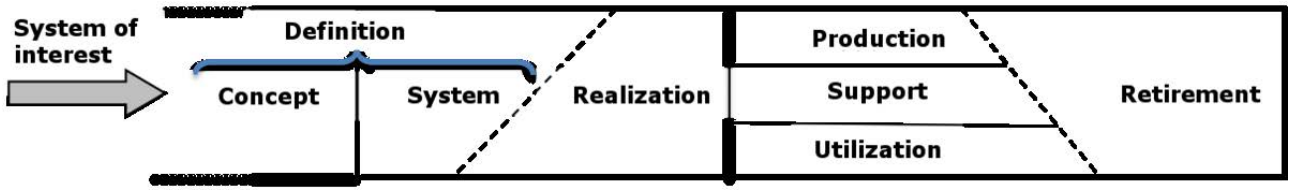

Figure 1. A Generic Life Cycle Model. (SEBoK Original)

Part 3 defines a collection of generic SE life cycle processes which define the activities and information needed across the SE life cycle. These processes include activities which contribute across the whole life cycle, with peaks of focused activity in certain stages (see Applying Life Cycle Processes for details).

The following sections provide a brief discussion of how SwE life cycle processes fit into SE life cycle process models. In practice, the details of this relationship are a key part of how a system life cycle is planned and delivered. The relationship will be shaped by the operating domain practice and solution type. Some examples of this are provided in the Implementation Examples.

Systems Engineering and Software Engineering Standards

The Systems Engineering life cycle processes described in Part 3, SE and Management, are largely based on those defined in the ISO/IEC/IEEE SE Life Cycle Processes 15288 Standard (2015).

The SWEBoK references the equivalent ISO/IEC/IEEE Software Engineering Life Cycle Processes 12207 Standard (2008), which defines a very similar set of processes for software systems. Figure 2 shows the relationship between the Enabling, Acquisition, Project and Technical Systems and Software processes in both 15288 and 12207 and the software specific processes of 12207. This alignment is from the last updates of both 12207 and 15288 in 2008. The SE processes have been further updated in 15288:2015, see Systems Engineering and Management for details. This change has not yet been applied to 12207. An update of 12207 was released in 2017, in which the alignment to 15288 was reviewed. See Alignment and Comparison of the Standards for more discussion of the relationships between the standards.

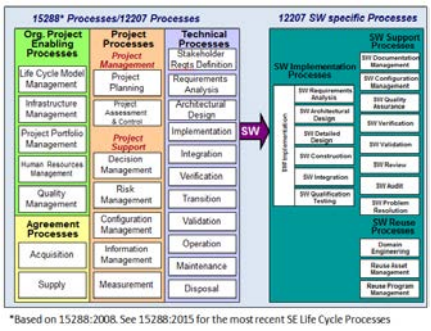

Figure 2. Aligned Process Models for ISO/IEC/IEEE 15288 & 12207: 2008 (Adapted from Roedler 2011). Reprinted with permission of Garry Roedler. All other rights are reserved by the copyright owner.

Systems Engineering and Software Engineering Life Cycle Relationships

Pyster et al. (2015) define two technical dimensions of engineered systems and of the engineering disciplines associated with them. The vertical dimensions of a system are those that modularize around technically focused engineering concerns involving specific elements of the system; the horizontal dimensions of a system involve cross-cutting concerns at the systems level. Examples of vertical concerns include quality attributes and performance effectiveness; and cost, schedule and risk of physical, organizational or human system elements associated with a particular technology domain. Examples of horizontal concerns include addressing evolving customer preferences that drive systems-level quality attributes, trade-off and optimization; resolving system architecture, decomposition and integration issues; implementing system development processes; and balancing system economics, cost, risk and schedule.

In complex systems projects, SE has a horizontal role while traditional engineering disciplines such as electrical, mechanical, and chemical engineering have vertical roles. To the extent that it is responsible for all aspects of the successful delivery of software related elements, SwE can be considered as one of the vertical disciplines. All of these traditional vertical disciplines will have some input to the horizontal dimension. However, the nature of software and its role in many complex systems makes SwE a critical discipline for many horizontal concerns. This is discussed further below.

The ISO/IEC/IEEE 12207 software engineering standard (2008) considers two situations:

- The life cycle of software products, containing minimal physical hardware, should use software specific processes and a simple life cycle
- The life cycle of systems with a significant software content (sometimes called software intensive systems) should integrate the software processes into the SE life cycle

The second of these situations is the one relevant to the practice of SE and requires a significant horizontal contribution from SwE.

The relationship central to this is the way **SwE Implementation Processes** (see Fig 2) are used in the SE life cycle to support the implementation of software intensive system elements. This simple relationship must be seen in the context of the concurrency, iteration and recursion relationship between SE life cycle processes described in Applying Life Cycle Processes. This means that, in general, software requirements and architecture processes will be applied alongside system requirements and architecture processes; while software integration and test processes are applied alongside system integration, verification and validation processes. These interrelationships help with vertical software concerns, ensuring detailed software design and construction issues are considered at the system level. They also help with horizontal concerns, ensuring whole system issues are considered and are influenced by an

understanding of software. See the Nature of Software for more details.

The ways these related processes work together will depend on the systems approach to solution synthesis used and how this influences the life cycle. If a top down approach is used, problem needs and system architecture will drive software implementation and realization. If a bottom up approach is used, the architecture of existing software will strongly influence both the system solution and the problem which can be considered. In Applying Life Cycle Processes, a "middle-out" approach is described which combines these two ideas and is the most common way to develop systems. This approach needs a two-way relationship between SE and SwE technical processes.

The **SW Support Processes** may also play these vertical and horizontal roles. Part 3 contains knowledge areas on both System Deployment and Use which includes operation, maintenance and logistics; and Technical Management Processes which covers the project processes shown in Figure 2. SwE support processes focus on the successful vertical deployment and use of software system elements and the management needed to achieve this. They also support their equivalent horizontal SE processes in contributing to the success of the whole system life cycle. The **Software Reuse Processes** have a particularly important role to play in deployment and use and Product and Service Life Management processes. The latter considers Service Life Extension; Capability Updates, Upgrades, and Modernization; and system Disposal and Retirement. All of these horizontal software engineering activities rely on the associated SE activities having a sufficient understanding of the strengths and limitations of software and SwE (see Key Points a Systems Engineer Needs to Know about Software Engineering).

The Life Cycle Models knowledge area also defines how Vee and Incremental life cycle models provide a framework to tailor the generic life cycle and process definitions to different types of system development. Both models, with some modification, apply equally to the development of products and services containing software. Thus, the simple relationships between SE and SwE processes will form the basis for tailoring to suit project needs within a selected life cycle model.

Software and Systems Challenges

Pyster et al. (2015) define three classes of software intensive systems distinguished by the primary sources of novelty, functionality, complexity and risk in their conception, development, operation and evolution. These are briefly described below:

- **Physical Systems** operate on and generate matter or energy. While they often utilize computation and software technologies as components, those components are not dominant in the horizontal dimension of engineering. Rather, in such systems, they are defined as discrete system elements and viewed and handled as vertical concerns.
- **Computational Systems** include those in which computational behavior and, ipso facto, software are dominant at the systems level. The primary purpose of these systems is to operate on and produce data and information. While these systems always include physical and human elements, these are not the predominant challenges in system development, operation and evolution.
- **Cyber-Physical Systems** are a complex combination of computational and physical dimensions. Such systems are innovative, functionally complex and risky in both their cyber and physical dimensions. They pose major horizontal engineering challenges across the board. In cyber-physical systems, cyber and physical elements collaborate in complex ways to deliver expected system behavior.

Some of the challenges of physical and computational systems are well known and can be seen in many SE and SwE case studies. For example, physical system life cycles often make key decisions about the system architecture or hardware implementation which limit the subsequent development of software architecture and designs. This can lead to software which is inefficient and difficult or expensive to change. Problems which arise later in the life of such systems may be dealt with by changing software or human elements. This is sometimes done in a way which does not fully consider SwE design and testing practices. Similarly, computational systems may be dominated by the software architecture, without sufficient care taken to consider the best solutions for enabling hardware or people. In

particular, operator interfaces, training and support may not be considered leading to the need for expensive organizational fixes once they are in use. Many computational systems in the past have been developed without a clear view of the user need they contribute to, or the other systems they must work with to do so. These and other related issues point to a need for system and software engineers with a better understanding of each other's disciplines. Pyster et al. (2015) consider how SE and SwE education might be better integrated to help achieve this aim.

Examples of cyber-physical systems increasingly abound – smart automobiles, power grids, robotic manufacturing systems, defense and international security systems, supply-chain systems, the so-called internet of things, etc. In these systems there is no clear distinction between software elements and the whole system solution. The use of software in these systems is central to the physical outcome and software is often the integrating element which brings physical elements and people together. These ideas are closely aligned with the Service System Engineering approach described in Part 4.

SEBoK Part 3 includes a Business and Mission Analysis process which is based on the equivalent process in the updated ISO/IEC/IEEE 15288 (2015). This process enables SE to be involved in the selection and bounding of the problem situation which forms the starting point for an engineered system life cycle. For cyber physical systems, an understanding of the nature of software is needed in the formulation of the problem, since this is often fundamentally driven by the use of software to create complex adaptive solution concepts. This close coupling of software, physical and human system elements across the system of interest continues throughout the system life cycle making it necessary to consider all three in most horizontal system level decisions.

The life cycle of cyber physical systems cannot be easily partitioned into SE and SwE achieving their own outcomes but working together on horizontal system issues. It will require a much more closely integrated approach, requiring systems and software engineers with a complementary set of competencies, and changes how the two disciplines are seen in both team and organizational structures. See Enabling Systems Engineering.

The Nature of Software

- Lead Authors:
- Tom Hilburn and Dick Fairley
- Contributing Author:
- Alice Squires

-

The nature of the software medium has many consequences for systems engineering (SE) of software-intensive systems. Fred Brooks has famously observed that four properties of software, taken together, differentiate it from other kinds of engineering artifacts (Brooks 1995). These four properties are:

1. complexity,
2. conformity,
3. changeability,
4. invisibility.

Brooks states:

> *Software entities are more complex for their size than perhaps any other human construct because no two parts are alike (at least above the statement level). If they are, we make the two similar parts into a subroutine — open or closed. In this respect, software systems differ profoundly from computers, buildings, or automobiles, where repeated elements abound.* (Brooks 1995, p 82)

Complexity

The complexity of software arises from the large number of unique interacting parts in a software system. The parts are unique because they are encapsulated as functions, subroutines, or objects, and invoked as needed rather than being replicated. Software parts have several different kinds of interactions, including serial and concurrent invocations, state transitions, data couplings, and interfaces to databases and external systems.

Depiction of a software entity often requires several different design representations to portray the numerous static structures, dynamic couplings, and modes of interaction that exist in computer software. Complexity within the parts and in the connections among parts requires that changes undergo substantial design rigor and regression testing. Software provides functionality for components that are embedded, distributed and data centric. Software can implement simple control loops as well as complex algorithms and heuristics.

Complexity can hide defects that may not be discovered easily, thus requiring significant additional and unplanned rework.

Conformity

Software, unlike a physical product, has no underlying natural principles which it must conform to, such as Newton's laws of motion. However, software must conform to exacting specifications in the representation of each of its parts, in the interfaces to other internal parts, and in the connections to the environment in which it operates. A missing semicolon or other syntactic error can be detected by a compiler, but a defect in the program logic or a timing error may be difficult to detect until encountered during operation.

Unlike software, tolerance among the interfaces of physical entities is the foundation of manufacturing and assembly. No two physical parts that are joined together have, or are required to have, exact matches. There are no corresponding tolerances in the interfaces among software entities or between software entities and their environments. There are no interface specifications for software stating that a parameter can be *an integer plus or minus 2%*. Interfaces among software parts must agree exactly in numbers, types of parameters and kinds of couplings.

Lack of conformity can cause problems when an existing software component cannot be reused as planned because it does not conform to the needs of the product under development. Lack of conformity might not be discovered until late in a project, thus necessitating the development and integration of an acceptable component to replace the one that cannot be reused. This requires an unplanned allocation of resources (usually) and can delay project completion.

Changeability

Software coordinates the operation of physical components and provides most of the functionality in software-intensive systems. Because software is the most malleable (easily changed) element in a software-intensive system, it is the most frequently changed element. This is particularly true during the late stages of a development project and during system sustainment. However, this does not mean that software is easy to change. Complexity and the need for conformity can make changing software an extremely difficult task. Changing one part of a software system often results in undesired side effects in other parts of the system, requiring more changes before the software can operate at maximum efficiency.

Invisibility

Software is said to be invisible because it has no physical properties. While the effects of executing software on a digital computer are observable, software itself cannot be seen, tasted, smelled, touched, or heard. Software is an intangible entity because our five human senses are incapable of directly sensing it.

Work products such as requirements specifications, design documents, source code and object code are representations of software, but they are not the software. At the most elemental level, software resides in the magnetization and current flow in an enormous number of electronic elements within a digital device. Because software has no physical presence, software engineers must use different representations at different levels of abstraction in an attempt to visualize the inherently invisible entity.

Uniqueness

One other point about the nature of software that Brooks alludes to but does not explicitly call out is the uniqueness of software. Software and software projects are unique for the following reasons:

- Software has no physical properties;
- Software is the product of intellect-intensive teamwork;
- Productivity of software developers varies more widely than the productivity of other engineering disciplines;
- Estimation and planning for software projects is characterized by a high degree of uncertainty, which can be at best partially mitigated by best practices;
- Risk management for software projects is predominantly process-oriented;
- Software alone is useless, as it is always a part of a larger system; and
- Software is the most frequently changed element of software intensive systems.

An Overview of the SWEBOK Guide

- Lead Authors:
- Hironori Washizaki, Maria-Isabel Sanchez-Segura, Juan Garbajosa, Steve Tockey, Kenneth E Nidiffer, and Annette D. Reilly

-

Software is everywhere. Software and systems engineers are leading the way for the digital transformation of social, economic, military, and environmental systems at an increasing rate of change. Advanced software-enabled capabilities allow software and systems engineers to address and anticipate emerging and complex challenges. Most systems of any complexity today are modeled and controlled by software; hence, the term “software intensive systems” is commonly used to describe them. At the end of 2022, the IEEE Computer Society (IEEE-CS) released beta version 4 of the Software Engineering Body of Knowledge (SWEBOK) (IEEE Computer Society 2022). When the final version 4.0 is published, it will replace version 3 which appeared in 2014 (Bourque and Fairley 2014). As have previous versions, SWEBOK 4.0 will help guide both systems engineering and software engineering professionals to long-established software life cycle processes and new insights for dealing with the demands of the digital era. This article uses SWEBOK 4.0 beta to explain how and why the new SWEBOK takes into consideration the needs of digital era software engineers immersed in an industry demanding visionary solutions.

Introduction

ISO/IEC/IEEE Systems and Software Engineering Vocabulary (SEVOCAB) defines software engineering as “the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, the application of engineering to software.” (ISO/IEC/IEEE n.d.)

It is important to note that systems engineering, and software engineering are distinct disciplines with different but somewhat overlapping core competencies. Due to the inherent characteristics of software intensive systems, these disciplines often approach problem solving from different perspectives. For example, systems engineers apply their problem-solving skills to develop physical, computational, social, and hybrid systems. Depending on the system, those skills could be based on a wide range of disciplines including mathematics, any of the physical and social sciences, law, management, and a myriad of other disciplines. Software engineers tend to apply their problem-solving skills on a narrower set of disciplines, especially discrete mathematics and computer science, to develop computational systems and subsystems. Also, software Is a logical medium. Software components of software-enabled systems are logical constructions expressed in algorithmic form. This contrasts with the physical and social components of systems that are realized through mechanical, electrical, chemical, biological, social, human and other elements. Both disciplines are critical to solving the complex challenges of the future as evidenced by disruptive innovation and increasing complexity in new systems and systems of systems which is causing a convergence among disciplines.

SWEBOK Guide Objectives

The Guide to the Software Engineering Body of Knowledge (SWEBOK), published by the IEEE Computer Society (IEEE CS), represents the current state of generally accepted, consensus-based knowledge emanating from the interplay between software engineering theory and practice. (Bourke and Fairley 2014, IEEE Computer Society 2022). The objectives include the provision of guidance for learners, researchers, and practitioners to identify and share a mutual understanding of “generally accepted knowledge” in software engineering. This guidance defines the boundary between software engineering and related disciplines, and provides a foundation for certifications and educational curricula.

The Guide should not be confused with the Body of Knowledge itself which exists in published literature. It is similar in this regard to the SEBoK. For example, the Guide addresses knowledge areas (KAs) in terms of “what” activities are being done versus “how” they are accomplished. Bodies Of Knowledge (BOKs) are often a formal way of referring to core competencies, or what should be known to be successful in a practitioner’s area of expertise. (Washizaki, et al. 2023) Every profession is based on a body of knowledge, although that knowledge is not always defined in a concise manner. In cases where normality exists, the body of knowledge is “generally recognized” by practitioners and may be codified in a variety of ways for a variety of different uses. But in many cases, a guide to a body of knowledge is formally documented, usually in a form that permits it to be used for such purposes as development and accreditation of academic and training programs, certification of specialists, or professional licensing. (IEEE Computer Society 2022, IEEE Computer Society 2014) The purpose of the Guide is to describe the portion of the Body of Knowledge that is accepted, to organize that portion, and to provide topical access to it. The Guide is also aligned with the following objectives:

1. To promote a consistent view of software engineering worldwide
2. To specify the scope of, and clarify the place of software engineering with respect to other disciplines such as computer science, project management, computer engineering, and mathematics
3. To characterize the contents of the software engineering discipline
4. To provide topical access to the Software Engineering Body of Knowledge
5. To provide a foundation for curriculum development and for individual certification and licensing material.

Overview of the SWEBOK Guide

The Guide represents the current state of accepted, consensus-based knowledge emanating from the interplay between software engineering theory and practice. The origins of the Guide go back to the late 1990s. Much like the software engineering discipline, the Guide has continued to evolve over the last 20 years to reflect the educational, industrial, social, technical, and technological changes in society. Version 4 of the Guide will be released in 2023 to improve its currency, readability, consistency, and usability.

Table 1 provides the high-level table of contents from Guide V4. Note that sections with an "*" are new (were not previously included in Guide 3). The current draft Guide V4 contains 18 knowledge areas (KAs), followed by several appendices. A KA is an identified area of software engineering defined by its knowledge requirements and described in terms of its concepts, component processes, practices, inputs, outputs, tools, and techniques. All KAs have been updated in V4 to reflect changes in software engineering since the publication of Guide V3. The new version reflects modern development practices, techniques, and the advancement of standards. Especially, agile and DevOps have been incorporated into almost all KAs since these models have been widely accepted since Guide V3 was published. Agile models typically have frequent demonstrations of working software to a customer in short iterative cycles with agile practices involving KAs. Furthermore, emerging platforms and technologies, including artificial intelligence (AI), machine learning (ML), and Internet of Things (IoT), have been incorporated into the foundation KAs. Also, there are three new KAs: Software Architecture, Software Operations, and Software Security. It is important to note there has also been more emphasis on Software Security in other relevant KAs such as software requirements. These additions better reflect contemporary software engineering practice, the pressing need to address cybersecurity as early as possible in developing distributed, networked systems, and non-distributed systems for use by the public at large, and the need for specialized skills to be able to work effectively in these areas.

Mathematical Foundations
Engineering Foundations

The 18 KAs in Guide V4 are:

KA1 - Software Requirements: Describes the activities involved in eliciting, analyzing, specifying, validating, and managing software requirements. The importance of requirements documentation for long-term maintenance is added. The "what's" and "how's" of work on software requirements in a project should be determined by the type of constructed software and not by the project life cycle. Also, it includes a deeper, broader coverage of requirements specification techniques, including model-driven requirements specification and acceptance criteria-based requirements specification.

KA2 – Software Architecture: This is a new KA resulting from a realization that architecture is a significant and distinct discipline over and above software design. Software architecture consists of fundamental structures of software elements, relations among them, and properties of both elements and relations. As software tends toward larger, ever more complex systems, architecture concerns move beyond construction to connectivity while assuring new levels of quality for safety, security, and dependability. Software architecture aims to "satisfice" all stakeholders, while the focus of software design is on the transformation of that vision into a feasible implementation.

KA 3 - Software Design: Focuses on the process of transforming requirements into a representation of the software system. Software is pervasive and critical in all aspects of modern life. The success of pervasive software depends on broadening the background of people with design skills, especially as emerging technologies, faster delivery times, and emphasis on agile, lean, and incremental design impact the development process.

KA4 - Software Construction: Covers the activities involved in translating the software design into executable code. This section has been updated to reflect modern construction techniques and practices: managing dependencies, cross-platform development and migration, feedback loops for construction, visual programming, and low-code/zero-code (i.e., called no code) platforms. Furthermore, major updates were made to some of the existing

sections, especially about reuse, life-cycle models, construction languages and environments.

KA5 - Software Testing: Deals with the various approaches and techniques used to assess software correctness and verify its conformance to requirements. This material has been revised to align with the shift left testing movement. This KA provides new content about software testing in recent development processes (like Agile, DevOps, and Test-Driven Development), application domains (like automotive, healthcare, mobile, legal, and IoT), emerging technologies (such as AI, blockchain, cloud) and quality attributes (like security and privacy).

KA6 - Software Engineering Operations: This is a new knowledge area that addresses the evolution of the role of software engineers to include DevOps and infrastructure as a Service (IaaS) activity while eliminating the organizational silos between development, maintenance, and operations. This new KA describes operations fundamentals, planning, delivery and control activities, and techniques.

KA 7 - Software Maintenance (SM): Software maintenance addresses fundamentals, processes, and techniques to provide cost-effective support for software in operation. Activities, such as determining the logistical support needed for the transition, are performed, and applied during the pre-delivery stage, whereas software surveillance, modification, training, and operating or interfacing with a help desk are post-stage activities. Software Maintenance categories and the software process have been updated to align with the 2022 version of ISO/IEC/IEEE 14764. (ISO/IEEE/IEEE 2022) Also, continuous integration, delivery, testing, and deployment have been added as a new topic in response to the growing popularity of regrouping development, maintenance, and operations tasks to improve software engineering productivity.

KA 8 - Software Configuration Management (SCM): Focuses on four basic functions of SCM: Configuration Identification: identifying all configuration items (CI) of a software system's state; Control changes: coordinating and limiting access to configurations in a software system; Configuration auditing: a series of reviews confirming that changes are being made to conform to a software system's desired state; and Status Accounting: automatically recording information about CIs, relationships, baselines and changes on any CI developed, as well as why they were made, when they were made, and who made them. In SWEBOK Guide V4, SCM has been explained considering all its facets. It stresses that the SCM process plan must be defined first before all the decisions and commitments included in the plan are somehow incorporated into existing tools for execution rather than the other way around, as was the usual practice in the past. Keeping track of configuration items (CI) relationships is essential to visualize the potential impact of a change on a CI over other CIs.

KA9 - Software Engineering Management: Describes the activities of the planning, organizing, estimating, and tracking of software projects. Practices are changing to meet the needs of society caused by increases in the size and complexity of software as well as greater pressure to quickly release software enabling products to market in rapidly changing environments. The results are fundamental management shifts in how work is performed.

KA10 - Software Engineering Process: Describes the activities, methods, and techniques used to define, implement, assess, and improve the software development process. Software engineers face a challenging and evolving, highly technological landscape due to fast-moving technology, societal events and changes, and a trend towards digitalization involving very many different domains. This is a point of no return that has facilitated the ongoing adoption of Agile and DevOps. Nevertheless, now more than ever, the software engineering processes applied to create products will continue to evolve, profiting from advances in the engineering dimension and learning, new and more advanced tools, and the latest knowledge from the other KAs. The KA describes this new consensus, highlighting the interaction with other KAs.

KA 11 - Software Engineering Models and Methods: Introduces different models, methods, and tools that support the software development process. Models have been updated and accurately classified by type. Aspect-oriented development has been added in the document as well as fundamental model-driven and model-based methods, have also been introduced. Agile methods have been extended a great deal to incorporate modern techniques, such as lean development, as well as large-scale and enterprise agile methods. On this note, DevOps and release engineering have also been introduced to clarify the release aspect of agile methods.

KA12 - Software Quality: Addresses the activities and techniques involved in achieving and evaluating software quality. This chapter was overhauled for alignment with notions of processes/product quality. It now includes new topics: (1) Software Dependability and Integrity Levels, (2) Standards, Models and Certifications, (3) Policies, Processes and Procedures, and (4) Quality Control and Testing.

KA13 – Software Security: This is a new knowledge area that focuses on the broader topics of security, particularly security fundamentals, security management, security tools, and domain-specific security, as well as major security engineering activities (such as security testing) that were briefly described under the Computing Foundations KA in the last SWEBOK edition. The existence of a separate KA emphasizes that security must be a first-class quality attribute in any development since almost any software system is connected to others, resulting in increased security risks.

KA14 - Software Engineering Professional Practice: Covers ethical considerations, professional codes of conduct, and the role of software engineering in society. Additions and revisions address the following areas: (1) Professional practices following generally accepted practices, standards, and guidelines set forth by the applicable professional societies, (2) User interface/user experience (UI/UX) inclusive design, (3) Considerations on diversity and inclusion, and (4) Considerations on agility.

KA15 - Software Engineering Economics: Focuses on the essence of engineering economics, the science of making decisions, and broadening the more traditional, purely financial view of engineering economics. Value does not always derive from money alone; that is, value can also derive from the "unquantifiable" such as, corporate citizenship, employee well-being, environmental friendliness, customer loyalty, and so on. This KA also focuses on more systematic pre-project decisions where a project is not under development but is being envisioned.

Note: Minor improvements in topic presentation in the next three KA 16-18. Discussions of Artificial Intelligence and Machine Learning were added. Furthermore, the revision includes a deeper coverage of measurement, particularly its implications for programming languages, and a more comprehensive discussion of root cause analysis.

KA16 - Computing Foundations: Covers the fundamental concepts and theories that underlie the discipline of software engineering.

KA 17 - Mathematical Foundations: Introduces mathematical techniques and principles relevant to software engineering, such as logic, probability, and discrete mathematics.

KA - 18 Engineering Foundations: Covers engineering principles and practices applicable to software engineering, including system engineering and project management.

Concluding Comments

A significant component of productivity today is the capabilities enabled by software systems. Software is a maturing science and engineering discipline; therefore, a need exists to continuously provide new guidance materials that reflect areas that are becoming important in modern software engineering. The Software Engineering Body of Knowledge Version V4 is a leading product which will help address this issue. It will serve as a reference for educators, practitioners, and organizations to understand the essential concepts and skills needed to design, develop, and maintain current and future software systems.

SWEBOK V4 represents the next step in the evolution of the software engineering profession and is written under the auspices of the Profession and Education Activities Board of the IEEE Computer Society. An international team of subject matter experts was assembled with the goal of developing the update. Given the purpose of this article, a significant portion of this document includes verbatim or near-verbatim elements of the SWEBOK Guide V4 which is about to go out for public review and that of (Washnizaki, et al. 2023) written by several members of the international team.

SWEBOK is described inside the SEBoK and there are some clear similarities and differences between the two BOKs. Each BOK is a comprehensive guide that outlines the core knowledge areas, principles, and best practices. SWEBOK concentrates specifically on the software engineering domain, providing a detailed overview of software development processes and methodologies. SEBoK, on the other hand, has a broader scope and addresses the entire systems engineering domain, including software and beyond, considering the interaction and integration of various components in complex systems.

Key Points a Systems Engineer Needs to Know about Software Engineering

- Lead Author:
- Dick Fairley
- Contributing Author:
- Alice Squires

-

The field of software engineering is extensive and specialized. Its importance to modern systems makes it necessary for systems engineers to be knowledgeable about software engineering and its relationship to systems engineering.

Key Concepts a Systems Engineer Needs to Know about Software Engineering

The following items are significant aspects that systems engineers need to know about software and software engineering. Most are documented in (Fairley and Willshire 2011):

1. **For the time, effort, and expense devoted to developing it, software is more complex than most other system components** - Software complexity arises because few elements in a software program (even down to the statement level) are identical, as well as because of the large number of possible decision paths found even in small programs, with the number of decision paths through a large program often being astronomical. There are several detailed references on software complexity. The SWEBOK (Bourque and Fairley 2014) discusses minimizing complexity as part of software construction fundamentals. Zuse (1991) has a highly cited article on software complexity measures and methods. Chapters 2 and 3 of the SWEBOK also have further references.
2. **Software testing and reviews are sampling processes** - In all but the simplest cases, exhaustive testing of software is impossible because of the large number of decision paths through most programs. Also, the combined values of the input variables selected from a wide combinatorial range may reveal defects that other combinations of the variables would not detect. Software test cases and test scenarios are chosen in an attempt to gain confidence that the testing samples are representative of the ways the software will be used in practice. Structured reviews of software are an effective mechanism for finding defects, but the significant effort required limits exhaustive reviewing. Criteria must be established to determine which components (or sub-components) should be reviewed. Although there are similar concerns about exhaustive testing and reviewing of physical products, the complexity of software makes software testing, reviews, and the resulting assurance provided more challenging. Other points include:
    1. All software testing approaches and techniques are heuristic. Hence, there is no universal "best" approach, practice, or technique for testing, since these must be selected based on the software context.
    2. Exhaustive testing is not possible.
    3. Errors in software tend to cluster within the software structures; therefore, any one specific approach or a random approach to testing is not advised.
    4. Pesticide paradox exists. As a result, running the same test over and over on the same software-system provides no new information.
    5. Testing can reveal the presence of defects but cannot guarantee that there will be no errors, except under the specific conditions of a given test.
    6. Testing, including verification and validation (V&V), must be performed early and continually throughout the lifecycle (end to end).
    7. Even after extensive testing and V&V, errors are likely to remain after long term use of the software.
    8. Chapter 4 of the SWEBOK discusses software testing and provides a bibliography.

3. **Software often provides the interfaces that interconnect other system components** - Software is often referred to as the *glue* that holds a system together because the interfaces among components, as well as the interfaces to the environment and other systems, are often provided by digital sensors and controllers that operate via software. Because software interfaces are behavioral rather than physical, the interactions that occur among software components often exhibit emergent behaviors that cannot always be predicted in advance. In addition to component interfaces, software usually provides the computational and decision algorithms needed to generate command and control signals. The SWEBOK has multiple discussions of interfaces: Chapter 2 on Software Design is a good starting point and includes a bibliography.
4. **Every software product is unique** - The goal of manufacturing physical products is to produce replicated copies that are as nearly identical as much as possible, given the constraints of material sciences and manufacturing tools and techniques. Because replication of existing software is a trivial process (as compared to manufacturing of physical products), the goal of software development is to produce one perfect copy (or as nearly perfect as can be achieved given the constraints on schedule, budget, resources, and technology). Much of software development involves altering existing software. The resulting product, whether new or modified, is uniquely different from all other software products known to the software developers. Chapter 3 of the SWEBOK provides discussion of software reuse and several references.
5. **In many cases, requirements allocated to software must be renegotiated and reprioritized** - Software engineers often see more efficient and effective ways to restate and prioritize requirements allocated to software. Sometimes, the renegotiated requirements have system-wide impacts that must be taken into account. One or more senior software engineers should be, and often are, involved in analysis of system-level requirements. This topic is addressed in the SWEBOK in Chapter 1, with topics on the iterative nature of software and change management.
6. **Software requirements are prone to frequent change** - Software is the most frequently changed component in complex systems, especially late in the development process and during system sustainment. This is because software is perceived to be the most easily changed component of a complex system. This is not to imply that changes to software requirements and the resulting changes to the impacted software can be easily done without undesired side effects. Careful software configuration management is necessary, as discussed in Chapter 6 of the SWEBOK, which includes extensive references.
7. **Small changes to software can have large negative effects** (A corollary to frequently changing software requirements: *There are no small software changes*) - In several well-known cases, modifying a few lines of code in very large systems that incorporated software negatively impacted the safety, security, and/or reliability of those systems. Applying techniques such as traceability, impact analysis, object-oriented software development, and regression testing reduces undesired side effects of changes to software code. These approaches limit but do not eliminate this problem.
8. **Some quality attributes for software are subjectively evaluated** - Software typically provides the interfaces to systems that have human users and operators. The intended users and operators of these systems often subjectively evaluate quality attributes, such as ease of use, adaptability, robustness, and integrity. These quality attributes determine the acceptance of a system by its intended users and operators. In some cases, systems have been rejected because they were not judged to be suitable for use by the intended users in the intended environment, even though those systems satisfied their technical requirements. Chapter 10 of the SWEBOK provides an overview of software quality, with references.
9. **The term *prototyping* has different connotations for systems engineers and software engineers** - For a systems engineer, a prototype is typically the first functioning version of hardware. For software engineers, software prototyping is primarily used for two purposes: (1) as a mechanism to elicit user requirements by iteratively evolving mock-ups of user interfaces, and (2) as an experimental implementation of some limited element of a proposed system to explore and evaluate alternative algorithms. Chapter 1 of the SWEBOK discusses this and provides excellent references.

10. **Cyber security is a present and growing concern for systems that incorporate software** - In addition to the traditional specialty disciplines of safety, reliability, and maintainability, systems engineering teams increasingly include security specialists at both the software level and the systems level in an attempt to cope with the cyber-attacks that may be encountered by systems that incorporate software. Additional information about System Security can be found in the Systems Engineering and Quality Attributes Part.
11. **Software growth requires spare capacity** - Moore's Law no longer fully comes to the rescue (Moore, 1965). As systems adapt to changing circumstances, the modifications can most easily be performed and upgraded in the software, requiring additional computer execution cycles and memory capacity (Belady and Lehman 1979). For several decades, this growth was accommodated by Moore's Law, but recent limits that have occurred as a result of heat dissipation have influenced manufacturers to promote potential computing power growth by slowing down the processors and putting more of them on a chip. This requires software developers to revise their programs to perform more in parallel, which is often an extremely difficult problem (Patterson 2010). This problem is exacerbated by the growth in mobile computing and limited battery power.
12. **Several Pareto 80-20 distributions apply to software** - These refers to the 80% of the avoidable rework that comes from 20% of the defects, that 80% of the defects come from 20% of the modules, and 90% of the downtime comes from at most 10% of the defects (Boehm and Basili 2001). These, along with recent data indicating that 80% of the testing business value comes from 20% of the test cases (Bullock 2000), indicate that much more cost-effective software development and testing can come from determining which 20% need the most attention.
13. **Software estimates are often inaccurate** - There are several reasons software estimates are frequently inaccurate. Some of these reasons are the same as the reasons systems engineering estimates are often inaccurate: unrealistic assumptions, vague and changing requirements, and failure to update estimates as conditions change. In addition, software estimates are often inaccurate because productivity and quality are highly variable among seemingly similar software engineers. Knowing the performance characteristics of the individuals who will be involved in a software project can greatly increase the accuracy of a software estimate. Another factor is the cohesion of the software development team. Working with a team that has worked together before and knowing their collective performance characteristics can also increase the accuracy of a software estimate. Conversely, preparing an estimate for unknown teams and their members can result in a very low degree of accuracy. Chapter 7 of the SWEBOK briefly discusses this further. Kitchenam (1997) discusses the organizational context of uncertainty in estimates. Lederer and Prasad (1995) also identify organizational and management issues that increase uncertainty; additionally, a recent dissertation from Sweden by Magazinus (2012) shows that the issues persist.
14. **Most software projects are conducted iteratively** - "Iterative development" has a different connotation for systems engineers and software engineers. A fundamental aspect of iterative software development is that each iteration of a software development cycle adds features and capabilities to produce a next working version of partially completed software. In addition, each iteration cycle for software development may occur on a daily or weekly basis, while (depending on the scale and complexity of the system) the nature of physical system components typically involves iterative cycles of longer durations. Classic articles on this include (Royce 1970) and (Boehm 1988), among others. Larman and Basili (2003) provide a history of iterative development, and the SWEBOK discusses this in life cycle processes in Chapter 8.
15. **Teamwork within software projects is closely coordinated** - The nature of software and its development requires close coordination of work activities that are predominately intellectual in nature. Certainly, other engineers engage in intellectual problem solving, but the collective and ongoing daily problem solving required of a software team requires a level of communication and coordination among software developers that is of a different, more elevated type. Highsmith (2000) gives a good overview.
16. **Agile development processes are increasingly used to develop software** - Agile development of software is a widely used and growing approach to developing software. Agile teams are typically small and closely

coordinated, for the reasons cited above. Multiple agile teams may be used on large software projects, although this is highly risky without an integrating architecture (Elssamadisy and Schalliol 2002). Agile development proceeds iteratively in cycles that produce incremental versions of software, with cycle durations that vary from one day to one month, although shorter durations are more common. Among the many factors that distinguish agile development is the tendency to evolve the detailed requirements iteratively. Most agile approaches do not produce an explicit design document. Martin (2003) gives a highly cited overview.

17. **Verification and validation (V&V) of software should preferably proceed incrementally and iteratively** - Iterative development of working product increments allows incremental verification, which ensures that the partial software product satisfies the technical requirements for that incremental version; additionally, it allows for the incremental validation (ISO/IEC/IEEE 24765) of the partial product to make certain that it satisfies its intended use, by its intended users, in its intended environment. Incremental verification and validation of working software allows early detection and correction of encountered problems. Waiting to perform integration, verification, and validation of complex systems until later life cycle stages, when these activities are on the critical path to product release, can result in increased cost and schedule impacts. Typically, schedules have minimal slack time during later stages in projects. However, with iterative V&V, software configuration management processes and associated traceability aspects may become complex and require special care to avoid further problems. Chapter 4 of the SWEBOK discusses software testing, and provides numerous references, including standards. Much has been written on the subject; a representative article is (Wallace and Fujii 1989).
18. **Performance trade-offs are different for software than systems** - Systems engineers use “performance” to denote the entire operational envelope of a system; whereas software engineers use “performance” to mean response time and the throughput of software. Consequentially, systems engineers have a larger design space in which to conduct trade studies. In software, performance is typically enhanced by reducing other attributes, such as security or ease of modification. Conversely, enhancing attributes such as security and ease of modification typically impacts performance of software (response time and throughput) in a negative manner.
19. **Risk management for software projects differs in kind from risk management for projects that develop physical artifacts** - Risk management for development of hardware components is often concerned with issues such as supply chain management, material science, and manufacturability. Software and hardware share some similar risk factors: uncertainty in requirements, schedule constraints, infrastructure support, and resource availability. In addition, risk management in software engineering often focuses on issues that result from communication problems and coordination difficulties within software development teams, across software development teams, and between software developers and other project members (e.g., hardware developers, technical writers, and those who perform independent verification and validation). See (Boehm 1991) for a foundational article on the matter.
20. **Software metrics include product measures and process measures** - The metrics used to measure and report progress of software projects include product measures and process (ISO/IEC/IEEE 24765) measures. Product measures include the amount of software developed (progress), defects discovered (quality), avoidable rework (defect correction), and budgeted resources used (technical budget, memory and execution cycles consumed, etc.). Process measures include the amount of effort expended (because of the people-intensive nature of software development), productivity (software produced per unit of effort expended), production rate (software produced per unit time), milestones achieved and missed (schedule progress), and budgeted resources used (financial budget). Software metrics are often measured on each (or, periodically, some) of the iterations of a development project that produces a next working version of the software. Chapter 8 and Chapter 7 of the SWEBOK address this.
21. **Progress on software projects is sometimes inadequately tracked** - In some cases, progress on software projects is not adequately tracked because relevant metrics are not collected and analyzed. A fundamental problem is that accurate tracking of a software project depends on knowing how much software has been developed that is suitable for delivery into the larger system or into a user environment. Evidence of progress in

the form of working software is one of the primary advantages of the iterative development of working software increments.

Software Engineering Features - Models, Methods, Tools, Standards, and Metrics

- Lead Author:
- Tom Hilburn

-

In recent decades, software has become ubiquitous. Almost all modern engineered systems include significant software subsystems; this includes systems in the transportation, finance, education, healthcare, legal, military, and business sectors. Along with the increase in software utility, capability, cost, and size there has been a corresponding growth in methods, models, tools, metrics and standards, which support software engineering.

Chapter 10 of the SWEBOK discusses modeling principles and types, and the methods and tools that are used to develop, analyze, implement, and verify the models. The other SWEBOK chapters on the software development phases (e.g., Software Design) discuss methods and tools specific to the phase. Table 1 identifies software engineering features for different life-cycle phases. The table is not meant to be complete; it simply provides examples. In Part 2 of the SEBoK there is a discussion of models and the following is one of the definitions offered: “an abstraction of a system, aimed at understanding, communicating, explaining, or designing aspects of interest of that system” (Dori 2002).

For the purposes of Table 1 the definition of a model is extended to some aspect of the software system or its development. As an example, “Project Plan” is listed as a model in the Software Management area. The idea is that the Project Plan provides a model of how the project is going to be carried out: the project team organization, the process to be used, the work to be done, the project schedule, and the resources needed.

Table 1: SWE Features (SEBoK Original)

Life-Cycle Activity	Models	Methods & Tools	Standards
Software Management	• Life-Cycle Process Model • Work Breakdown Structure • Constructive Cost Model (COCOMO) • Project Plan • Configuration Management (CM) Plan • Risk Management Plan	• Effort, Schedule and Cost Estimation • Risk Analysis • Data Collection • Project Tracking • CM Management • Iterative/Incremental Development • Agile Development	• [IEEE 828] • [IEEE 1058] • [IEEE 1540] • [IEEE 12207]
Software Requirements	• Functional Model • User Class Model • Data Flow Diagram • Object Model • Formal Model • User Stories	• Requirements Elicitation • Prototyping • Structural Analysis • Data-Oriented Analysis • Object-Oriented Analysis • Object Modeling Language (OML) • Formal Methods • Requirements Specification • Requirements Inspection	• [IEEE 830] • [IEEE 1012] • [IEEE 12207]
Software Design	• Architectural Model • Structure Diagram • Object Diagram • Class Specification • Data Model	• Structured Design • Object-Oriented Design • OML • Modular Design • Integrated Development Environment (IDE) • Database Management System (DBMS) • Design Review • Refinement	• [IEEE 1012] • [IEEE 1016] • [IEEE 12207] • [IEEE 42010]
Software Construction	• Detail Design Document • Pseudocode • Flow Chart • Program Code • Unit Test Plan • Integration Test Plan	• Detailed Design • Functional Programming • Object-Oriented Programming • IDE • DBMS • Black Box/White Box Testing • Basic Path Testing • Unit Testing • Code Review • Proof of Correctness • Software Reuse • Integration • Integration Testing	• [IEEE 1008] • [IEEE 1012] • [IEEE 1016] • [IEEE 12207]
Software Testing	• System Test Plan • Reliability Model • Software Maintenance Process	• Usability Testing • System Testing • Acceptance Testing • Regression Testing • Reliability Testing • Non-Functional Software Testing	• [IEEE 829] • [IEEE 1012] • [IEEE 12207]
Software Maintenance	• Software Maintenance Process	• Automated Testing Tools • Maintenance Change • Impact Analysis • Inventory Analysis • Restructuring • Reverse Engineering • Re-engineering	• [IEEE 1219] • [IEEE 12207] • [IEEE 14764]

Software Metric

A software metric is a quantitative measure of the degree a software system, component, or process possesses a given attribute. Because of the abstract nature of software and special problems with software schedule, cost, and quality, data collection and the derived metrics are an essential part of software engineering. This is evidenced by the repeated reference to measurement and metrics in the SWEBOK. Table 2 describes software metrics that are collected and used in different areas of software development. As in Table 1 the list is not meant to be complete, but to illustrate the type and range of measures used in practice.

Table 2: Software Metrics * (SEBoK Original)

Category	Metrics
Management Metrics	• Size: Lines of Code (LOC*), Thousand Lines of Code (KLOC) • Size: Function points, Feature Points • Individual Effort: Hours • Task Completion Time: Hours, Days, Weeks • Project Effort: Person-Hours • Project Duration: Months • Schedule: Earned Value • Risk Projection: Risk Description, Risk Likelihood, Risk Impact
Software Quality Metrics	• Defect Density - Defects/KLOC (e.g., for system test) • Defect Removal Rate – Defects Removed/Hour (for review and test) • Test Coverage • Failure Rate
Software Requirements Metrics	• Change requests (received, open, and closed) • Change request frequency • Effort required to implement a requirement change • Status of requirements traceability • User stories in the backlog
Software Design Metrics	• Cyclomatic Complexity • Weighted Methods per Class • Cohesion - Lack of Cohesion of Methods • Coupling - Coupling Between Object Classes • Inheritance - Depth of Inheritance Tree, Number of Children
Software Maintenance and Operation	• Mean Time Between Changes (MTBC) • Mean Time to Change (MTTC) • System Reliability • System Availability • Total Hours of Downtime

**Note: Even though the LOC metric is widely used, using it comes with some problems and concerns: different languages, styles, and standards can lead to different LOC counts for the same functionality; there are a variety of ways to define and count LOC– source LOC, logical LOC, with or without comment lines, etc.; and automatic code generation has reduced the effort required to produce LOC.*

Systems Engineering and Mechanical Engineering

- Lead Authors:
- Leigh McCue and John Shortle
- Contributing Author:
- Art Pyster

-

This treatment opens with a brief overview of subdisciplines of mechanical engineering. The interested reader seeking a more thorough study on Mechanical Engineering (ME) is referred to Sagdeh and Worek (2017) and other references identified below. As stated by Hibbeler (2015), "Mechanics is a branch of the physical sciences that is concerned with the state of rest or motion of bodies that are subjected to the action of forces. In general, this subject can be subdivided into three branches: rigid-body mechanics, deformable-body mechanics, and fluid mechanics." It is with those branches that this summary begins, before delving into thermodynamics, controls, and mechanical engineering design and the relationship between SE and ME.

Rigid-Body Mechanics and Deformable Body Mechanics

Mechanical engineering and civil engineering structural analysis bear much in common, as both fundamentally seek to create structures to satisfy a design need. While the bridge designer may prioritize material selections that hold up under constant use and varying weather conditions, the race car designer may prioritize light weight while maintaining crash worthiness. In the process of structural analysis, one applies Newton's laws to analyze loads at joints and calculates internal forces, shear, and moment on structural elements. By understanding the loads a joint or structural element must withstand, one can select materials with appropriate properties to prevent failure. A structural element that changes its shape under load is known as a deformable body, whereas a body for which the distances between points on the body remain constant regardless of loading is known as a rigid body. The study of static structures, solid mechanics, and materials are typically foundational in a mechanical engineering undergraduate curriculum (e.g. (Hibbeler 2015), (Philpot and Thomas 2020), and (Callister and Rethwich 2019)).

Dynamics

A subset of mechanics is dynamics. Eloquently summarized by Greenwood (1965), "[t]he science of mechanics is concerned with the study of the interactions of material bodies. Dynamics is that branch of mechanics which consists of the study of the motions of interacting bodies and the description of these motions in terms of postulated laws." In static rigid-body mechanics, with structures that are not accelerating, we write Newton's second law as $\Sigma F=0$. In dynamics we utilize $\Sigma F=ma$ and leverage conservation of energy and momentum in analyzing systems. Simple dynamics problems typically involve the swinging of a pendulum or a spring-mass-damper system and evolve in complexity to modern suspension systems, orbital dynamics, and the multi-body challenges one might see when landing a rescue helicopter on the deck of a Coast Guard vessel.

Fluid Mechanics

Fluid mechanics includes experimental, computational, and analytical modeling of forces on a body moving in a liquid. Models of fluid dynamics often utilize the Navier-Stokes equations [1], a collection of partial differential equations arising from conservation of mass and momentum. For inviscid flows, the Navier-Stokes equations can be simplified to the Euler equations [2]. The Euler equations can be further simplified to Bernoulli's equation [3] in the special case of steady, incompressible, irrotational flow along a streamline. Common dimensionless parameters to characterize a flow include Reynolds number [4], Froude number, and Mach number. Reynolds number is a measure of the inertial forces to viscous forces, Froude number [5] characterizes the ratio of inertial forces to gravitational forces, and Mach number [6] provides a ratio of flow speed to the speed of sound. A comprehensive introductory text on fluid mechanics is Batchelor (2000).

Thermodynamics

Mechanical engineering thermodynamics involves products where heat is a primary consideration in the generation or transfer of energy – examples include engines, refrigeration systems, and nuclear reactors. At a broad level, the study of thermodynamics is captured by the following laws:

- *Zeroth law:* "[W]hen two bodies are in thermal equilibrium with a third body, they are in thermal equilibrium with one another." (Moran and Shapiro 1998).
- *First law:* "[T]he value of the net work done by or on a closed system undergoing an adiabatic process between two given states depends solely on the end states and not on the details of the adiabatic process." (Moran and Shapiro 1998). In short, energy can be neither created nor destroyed.
- *Second law:* "It is impossible for any system to operate in such a way that the sole result would be an energy transfer by heat from a cooler to a hotter body." (Moran and Shapiro 1998). Notably, the first and second laws together are what render a perpetual motion machine physically impossible.
- *Third law:* "[T]he entropy of a pure crystalline substance is zero at the absolute zero of temperature..." (Moran and Shapiro 1998).

Relating thermodynamics to the mechanics topics described above, in a comprehensive summary paper, Graham Baker quotes Clifford Truesdell stating "As mechanics is the science of motions and forces, so thermodynamics is the science of forces and entropy." (Baker 2005).

Controls

Controls refers to "the process of causing a system variable to conform to some desired value, called a reference value." (Franklin et al. 1994) In application, this requires assimilating knowledge of the above disciplines to devise a system to achieve a desired outcome; e.g. measuring room temperature and using that as feedback to control an HVAC system, or measuring orientation and angular velocity to ideally time the firing of a spacecraft thruster to achieve a target orbit.

Design

In design, one combines knowledge of these specific fields to develop products of need by a customer or society. The Accreditation Board for Engineering and Technology (ABET) definition of design is agnostic to engineering discipline; specifically, they state "Engineering design is a process of devising a system, component, or process to meet desired needs and specifications within constraints. It is an iterative, creative, decision-making process in which the basic sciences, mathematics, and engineering sciences are applied to convert resources into solutions. Engineering design involves identifying opportunities, developing requirements, performing analysis and synthesis, generating multiple solutions, evaluating solutions against requirements, considering risks, and making trade-offs, for the purpose of obtaining a high-quality solution under the given circumstances." (ABET n.d.) In the design

process, mechanical engineers use their knowledge of these disciplines to address societal needs. Furthermore, a key aspect of mechanical engineering design is the decision-making process. As such, decision theory is a key component to the study of design. (Tebay et al. 1984). Approaches to mechanical engineering design vary from waterfall (sequential) style to agile (parallel) methods, with waterfall methods more likely to be governed by a design spiral leading to a single point design whereas agile methods are iterative. Set-based design has become increasingly common in recent years, gaining benefit from increased flexibility by pursuing a broad design space, eliminating options over time as data and validation of underlying assumptions warrant. (Scaled Agile n.d.)

Application to Related Subdisciplines

These fundamental knowledge areas provide core skills for deeper knowledge in numerous subdisciplines, often taught as standalone multi-disciplinary fields. For example:

Aerospace Engineering

Aircraft and spacecraft require command of each of these core areas. For example fluid-dynamics permits understanding the forces of lift and draft on a body. Thermodynamics allows modeling thermal effects on engines, craft operating at high speeds, or subject to large thermal load fluctuations in space. Application of knowledge of dynamics and control allows engineers to develop safe, operable vehicles with performance traits tailored to design need. Expertise in mechanics and materials allows one to develop light weight structures. And ultimately, the design process enables the development and refinement of prototype and production vehicles. Aircraft provide numerous examples of the ties between mechanical engineering and systems engineering. For example, a Boeing 747 has approximately 6 million parts, provided by over 550 suppliers (Boeing 2013), relying on supply chain management. Furthermore, an airline fleet becomes a system of aircraft with the air traffic network constituting a system of systems.

Naval Engineering

Naval engineers function in many ways as systems engineers. Recognizing, for example, the wide range of engineering complexities involved in designing, building, and operating an aircraft carrier – from hull, mechanical, and electrical system design, to hydrodynamics and maneuvering, to integrated warfare systems, to aircraft operations, to hotel services for crew, the modern naval combatant is a highly complicated system of systems. A representative reference is provided in Lamb (2003).

Codes and Standards

The American Society of Mechanical Engineers (ASME) has been involved in the development of codes and standards for mechanical engineering systems since its first standard, "Code for the Conduct of Trials of Steam Boilers" released in 1884. (ASME n.d.a) As a testament to the complexity of mechanical engineering systems, in the present day, ASME standards are used in more than 100 countries and cover topics as diverse as elevators to nuclear plants with guidance under development for additive manufacturing and robotics, amongst other fields. (ASME n.d.)

Relationship between Mechanical and Systems Engineering

ME emphasizes design, development, and research on dynamic systems, be it turbines, prosthetics, or autonomous vehicles. Mechanical engineering products often form the building blocks for systems of systems; for example, a materials scientist designs the fan blade that goes into another mechanical engineer's turbine engine design which resides on an aerospace engineer designed fighter jet, operating off an aircraft carrier designed by naval and systems engineers. One of the best examples of the relationship between ME and SE is with regard to human systems integration, in which multidisciplinary teams assess topics such as ergonomics, health, safety, user interface design,

and human performance in designing mechanical systems. Systems engineers often lead such assessments. A comprehensive reference on human systems integration is Booher (2003).

Relatively junior mechanical engineers often focus heavily on the individual subdisciplines of ME, such as those described earlier in this article. They might, for example, conduct a structural analysis of an individual physical assembly. As mechanical engineers gain experience and take on more senior roles, they often become concerned with the larger context in which mechanical components fit and hence take on many of the roles that systems engineers perform but with a focus on the mechanical subsystems. This becomes quite evident when looking at advertisements for senior mechanical engineers. For example, in a May 2022 listing of 20 senior mechanical engineer positions on one online job site, responsibilities included such systems engineering activities as reviewing mechanical documents for areas of conflict with all disciplines, resolving discrepancies between the employer and customer requirements, working with external partners and projects to ensure interoperability of internal and external components, driving internal development methodology, owning the full life cycle for parts, and managing the quality of deliverables while coordinating with other project disciplines.

Knowledge Area: Systems Engineering and Enterprise IT

Systems Engineering and Enterprise IT

- Lead Authors:
- Chuck Walrad and Rich Hilliard

-

SE is integral to the effective functioning of Enterprise Information Technology (EIT) organizations, which are devoted to the successful realization, use, and retirement of engineered systems that are largely based on information technology. Effective means to develop, manage, and support EIT organizations are described in the Enterprise Information Technology Body of Knowledge (EITBOK), which was jointly developed by the IEEE Computer Society and ACM, and is maintained as a public wiki by the IEEE (IEEE/ACM n.d.). This article largely explains EIT organizations through the lens of the EITBOK and how it relates to SE principles, practices, and activities as described elsewhere in the SEBoK.

Enterprise IT Introduction

Systems Engineering is integral to the effective functioning of EIT organizations, whose work is devoted to the successful realization, use, and retirement of engineered systems that are largely based on information technology. Examples of EIT systems include enterprise resource planning, supply chain management and customer relationship management systems, accounting, finance, inventory and order management, marketing, planning, purchasing, and sales. In the late 1980s and throughout the 1990s, EIT organizations became increasingly aware that the success rates of IT projects were very low, and that their enterprise customers were increasingly unhappy with their EIT investments. The Standish Group sought to understand what was going on. Their findings were presented in Standish (1994). The Standish Group research shows a staggering 31.1% of projects were canceled before they ever got completed. Further results indicated 52.7% of projects cost 189% of their original estimates. The cost of these failures and overruns were just the tip of the proverbial iceberg. The lost opportunity costs were not measurable but could easily be in the trillions of dollars.

As a result, commercial IT organizations through the auspicious parallel emergence of the Total Quality Management movement (ASQ n.d.) and the increasingly widespread development of application development methodologies by IT management consulting firms, recognized the need for the principles of SE and cross-functional teams (sometimes called Integrated Product Teams (IPTs)). It should be noted that there is considerable overlap today between SE and Project Management (PM) (see Systems Engineering and Project Management). Note that the following business management activities can be supported by Enterprise Systems Engineering (ESE) activities:

- mission and strategic planning
- business processes and information management
- performance management
- portfolio management
- resource allocation and budgeting
- program and project management

These same areas are often supported by Project Management Offices. However, since a key difference between PM and SE is that the latter includes technical expertise in the product/system of concern, focus should be on SE and

IPTs.

With IPTs, each product is shepherded from concept through delivery and support to retirement by a cross-functional team that includes representatives from each area of responsibility, such as customer requirements development, design and development, test, configuration management, release engineering, delivery, and support.

As enterprises have come to depend more and more on technology to perform effectively, EIT organizations have matured, often due to the influence of IT consulting firms that make it their business to keep abreast of best practices.

EIT Concepts

Much of this section builds on concepts found in the EITBOK, the *Guide to the Enterprise Information Technology Body of Knowledge* (IEEE/ACM n.d.), and on general SE concepts elsewhere in the SEBoK.

An enterprise may be viewed from various perspectives: such as a system or system of systems (SoS):

- system-like enterprise: enterprises, like other systems, may have a tight coupling, single-executive function;
- system of systems-like enterprise: may be a loosely coupled group of organizations with blurred boundaries and (yet) with (some) shared outcomes.

The choice of perspective may vary with many factors: the enterprise itself, the mission or purpose, or the particular engineering task at hand. The enterprise can be viewed as a system with inputs and outputs in relation to the outside world, or as a system of systems interacting through its individual component inputs and outputs.

An enterprise usually involves one or more organizations but need not be identified with the organization. As the scope of human and organizational participants of the enterprise widen, there may be no single point of control. For example, an extended enterprise could include a company, its suppliers and its customers.

Whatever perspective is taken (system-like, SoS-like, other), there are common key ingredients of any enterprise: capabilities, individual competencies, and the organizational design. Capabilities can be further categorized into organizational, system, and operational. These capabilities determine what the enterprise is able to produce, which may be external offerings or internal mechanisms. Operational capabilities create services and products which in turn produce value as determined by stakeholders. The capabilities of an enterprise are realized through various enterprise elements including hardware, software, personnel, facilities, data, materials, techniques, and even services which include soft items such as processes, principles, policies, practices, organizations, doctrine, theories, and beliefs.

EIT capabilities exist through lifecycles spanning from creation through eventual replacement and disposal. System Life Cycle Models aid in understanding, designing, planning and managing the capability of interest. As stated in the EITBOK, “A life cycle for a system generally consists of a series of stages regulated by a set of management decisions which confirm that the system is mature enough to leave one stage and enter another. Basic life cycle terms and concepts are discussed in Life Cycle Terms and Concepts. Some typical life cycles are discussed in System Life Cycle Models.

A life cycle-based approach can be deployed across the several levels and used to manage evolution. These levels are:

- the enterprise itself
- the processes and organizations constituting the enterprise
- the systems enabling the capabilities, services or products provided.

It is important to distinguish between *product* and *project* lifecycle models. A product’s life cycle extends from its initial concept approval, through development and distribution, to its retirement. This is the cycle that is managed within an Enterprise IT organization, since EIT must manage the hardware or software product from its introduction (in the case of acquired capabilities) or from its concept approval and development (in the case of capabilities it builds), through its deployment, maintenance and eventual retirement or withdrawal. Each of these stages is usually managed as a project or a series of projects. However, most discussions of life cycles within software and systems

discussions focus on *project* life cycles. See, for example, the *Software Extension to PMBOK Guide* (PMI 2013).

System of Systems Context in EIT

The phrase "Enterprise IT" (EIT) is often used both to refer to the technology organization/business unit within the enterprise and to the enterprise's information technology systems. This can be confusing. Here EIT refers to technology systems. When referring to the organization, "Enterprise IT organization" or EIT organization is used instead.

Enterprise IT organizations are responsible for complex socio-technical systems. Socio-technical systems in a business context (thus, EIT) contain technical elements (software, hardware, networks, storage, databases, etc.) but they also contain essential human components and necessary business processes. As covered in Introduction to Systems Engineering Fundamentals, they exist in an engineered System Context that is a set of system component interrelationships within a real-world environment:

This includes where problems come from and how they are defined, how candidate solutions are identified and selected, how to balance technology and human elements in the wider solution context, how to manage the complex organizational systems needed to develop new solutions, and how developed solutions are used, sustained and disposed of. SE should consider the full engineered system context so that the necessary understanding can be reached and the right systems engineering decisions can be made.

Socio-technical systems also have the following key characteristics: *Openness* in that they strongly interact with their environments, and *unfinished* in that they evolve over time. A complex of EIT systems is essential to the successful functioning of the people in the enterprise. They rely on EIT's technology for communication, paying employees, people management, business measurement, and often for managing supply chains. Thus, "EIT needs to be viewed as a strategic partner to all the other functions and business units within an enterprise. This means that the results produced by EIT along with its effectiveness and efficiency are all critically important to the success of the enterprise." (IEEE/ACM n.d. (a))

To accomplish this mission, the EIT organization builds and acquires new systems or system components, integrates them into the mega SoS, and maintains the integrity and interoperability of the individual components as well as the integrity of the entire complex of systems. In addition, security and performance levels must be achieved, benchmarked, and maintained or improved.

Major concerns of the EIT Organization

The EITBOK provides a good deal of information about major organizational concerns. Five of those concerns are summarized here:

- Enterprise Architecture
- Strategy and Governance
- Change
- Interoperability of Component Systems
- Security of Systems and Data

Enterprise Architecture

The EITBOK defines Enterprise Archirecture (EA) as the practice of conducting enterprise analysis, design, planning, and implementation using a holistic approach for the successful development and execution of strategy. There are, in fact, many alternative definitions common in the community. See enterprise architecture for several of them, including the one from the EITBOK. EA applies architecture principles and practices to guide organizations through the business, information, process, and technology changes necessary to execute their organization's strategies. EA builds upon many of the concepts and practices of Systems Architecture and also software architecture

(Bourque & Fairley 2014).

This section will discuss EA from the perspective of key Principles of Systems Thinking, designated in this article with ***bold italics***. There are many commonalities in architecture whether one is architecting in systems, software or the enterprise. This article highlights both commonalities and differences between Enterprise Architecture and Systems Architecture. Architecture takes place at the juncture of design problems and their solutions. Design problems rarely arrive fully formulated or "hatched" for the architect; much of the architecture effort is to analyze or formulate the problems to be solved. Often this involves negotiation both within the enterprise and with outside stakeholders. Possible solutions are limited by resources and schedule and therefore often must also be negotiated.

A dominant principle of EA is ***separation of concerns*** (SoC). This is due to the complexity of enterprises, with many forces acting upon them; the many technologies and disciplines involved in their creation and day-to-day operations; and due to the diversity of stakeholders involved in the enterprise (see *EIT Roles* below).

An application of SoC is the ***boundary*** principle which is crucial to separate what is "inside" the enterprise from what is "outside". While the former is often under the enterprise's control, the latter is often beyond its control.

For some systems, determining the boundary is a key decision, subject to many possibilities and consequences. This is perhaps less the case for enterprises whose bounds are determined by the extent of organizations, regulations, supply chains or other criteria. Within an established boundary, the ***holism*** principle applies: to treat the enterprise as a unified whole, and, in particular, with respect to the ***interaction*** of the enterprise with its *environment*—including stakeholders, other enterprises and systems. From an EIT perspective, an enterprise is a system of systems. SoC offers a way to focus on the constituent systems in terms of their interconnections to one another to form the enterprise.

Another useful application of SoC is to apply the principle of ***views*** to depict the architecture of the enterprise in different ways to address the diverse interests (i.e., *concerns*) of an enterprise's various stakeholders. Each *architecture view* presents a specific perspective on the enterprise. To be understandable to its audiences (those various stakeholders), each view should follow the conventions of its *architecture viewpoint* (ISO/IEC/IEEE 2011). Just as a map should have a legend, each view should have a documented viewpoint providing a prescribed set of conventions for looking at the enterprise through the resulting view. A viewpoint definition serves as a contract between the architect and stakeholders on *how* a selected set of concerns are to be addressed. Each viewpoint allows the architect to consider the enterprise in terms of various kinds of elements and relations among them and to present that view to those "concerned" stakeholders. Dominating concerns in enterprise architecture include interoperability, quality of systems and services, operations, managing change, and alignment with the enterprise's mission, market, and technology. Via the principle of ***dualism***, it is recognized that some viewpoints are paired, such as with process/data duality. Another pervasive duality in the enterprise is of people/technology in terms of what capabilities are automated and which are performed by people.

In support of EA, there are numerous *enterprise architecture frameworks* each providing a pre-defined, integrated set of viewpoints to frame typical, recurring concerns (ISO/IEC/IEEE n.d.). The earliest recorded framework was Hammer et al. (1986), developed in the mid-1980s in response to growing availability of distributed computing to the enterprise (Rivera 2013). In the late 1980s, the US National Institute of Standards and Technology (NIST) created its Enterprise Architecture Model as a guide for US federal departments to organize their IT offerings (Fong and Goldfine 1989). NIST's 5-layer model remains influential today. Despite never using the term "enterprise," Zachman's information systems architecture has had a major influence on how subsequent frameworks have been organized and depicted using grids or cubes. Later frameworks have evolved in response to emerging concepts, such as the move from client-server to service-oriented applications, as in the OASIS SOA Reference Model and its associated framework. The 1990s saw a proliferation of frameworks for defense enterprises including US DODAF, UK MODAF, NATO's NAF and their successors such as OMG's UAF.

Yet another application of ***separation of concerns*** is distinguishing today's needs versus facilitating future needs; balancing ***stability/change*** and highlighting the temporal planning aspect of architecture of the enterprise. In concert

with applying SoC, the architect uses the principle of ***abstraction*** to "forget" some details of the subject and thus focus on essentials. Just as SoC is a way of taking things apart, ***abstraction*** is a way of unifying or putting like things together through generalization. These two principles are perhaps the most central to architecture. SoC and abstraction work together: SoC picks out subjects and abstraction helps architects to focus upon the essentials of each subject.

Returning to the ***boundary*** and ***holism*** principles, the enterprise architect applies these recursively. As architecting proceeds, the internal details of the enterprise become known in terms of ***interaction*** among its parts and other ***relations***. Again, ***multiple views*** are used to factor specific ***relations*** into distinct views. Typical relations include Causality, Dependency, Client-Server, and Input-Output.

There are a variety of ways to structure the enterprise based upon stakeholder needs, mission or charter, technologies or capabilities already in place. Among these are structuring principles including:

- ***Modularity*** (separate and group capabilities into modules by commonalities)
- ***Network*** (modules are linked together)
- ***Encapsulation*** (separating architecture modules use from how they are implemented)
- ***Layer Hierarchy*** (separation through gradual refinement)
- ***Regularity*** (uniformity of interactions, of structure within layer, within network)
- ***Similarity/Difference*** (recognizing the limits of Regularity)

Strategy and Governance

EIT governance is the established process to define the strategy for the EIT organization and oversee its execution to achieve enterprise goals. Strategic planning translates the larger enterprise's goals into EIT goals and defines what EIT must do to achieve them. The EIT governance effort should communicate EIT goals, how they support the larger organization's goals, and drive change to achieve them while maintaining agreed upon levels of operation.

The systems thinking principle of ***parsimony*** applies here, too. For example, the simplest possible measurement and reporting systems are most likely to be used and not corrupted. Similarly, the EIT organizational structure should be straightforward and easy to traverse so that staff can communicate and problem-solve in teams. In governing the EIT organization to meet its dual goals of satisfying its customers and meeting its budget and schedule commitments, EIT management encounters the difficulty of managing in the face of ***dualism***. The most obvious instance of handling ***dualism*** in EIT is the trade-off between budget, project prioritization, and features within projects.

Change

There are two levels of change management discussed in the EITBOK: organizational change management and changes to the IT organization's assets, whether they be software, hardware, or telecommunications systems. In the larger sense, the introduction of new systems and services often also requires changes in people's jobs and in the processes used to accomplish those jobs. Such efforts are intended to increase business value. Such changes require change initiatives because they involve guiding a mixture of stakeholders through the change process. This is one aspect of change management. Change also occurs when existing systems or services must be updated to meet new needs. Depending on the scope of the proposed changes, a change initiative may be required in this situation, too. At any rate, a change request process must be initiated and tracked to disposition (deferral, rejection, or implementation). Changes also come about as a result of defect reports. In such cases, the defect report must be tracked throughout the report's life cycle, to disposition (deferral, rejection, or implementation). These latter types of change management are discussed in detail in the EITBOK.

Interoperability of Component Systems

As explained in the EITBOK, *interoperability* means “the ability of systems (including organizations) to exchange and use exchanged information without knowledge of the characteristics or inner workings of the collaborating systems (or organizations).” This definition is based on an ISO definition: “degree to which two or more systems, products, or components can exchange information and use the information that has been exchanged.” (ISO/IEC 2011) Note that this definition includes hardware components as well as software systems and the organizations in which they are used.

Because technology changes so rapidly, and organizations themselves are frequently changing, achieving and maintaining interoperability is crucial. It is one of the main reasons that providing IT services is difficult and how it differs from engineering and delivering finished products, whether off-the-shelf products or bespoke systems.

Security of Systems and Data

According to former FBI Director Robert Mueller in 2012, "There are only two types of companies: those that have been hacked, and those that will be." Two years later, his successor, James Comey said "There are two kinds of big companies in the United States. There are those who've been hacked by the Chinese and those who don't know that they've been hacked by the Chinese." Achieving and maintaining acceptable security is daunting but necessary.

While there are many definitions for security, most include the three dimensions of confidentiality, integrity, and availability. As such, the primary goal of EIT security is to preserve the confidentiality, integrity, and availability of information and information systems.

The principles behind an organization’s information security management system should be to design, implement, and maintain a coherent set of policies, processes, and systems that keep the risks associated with its information assets at a tolerable level, and yet, manage the cost and inconvenience of said risk management. As such, according to the EITBOK, EIT security practices should strive to enable the organization to:

- Always understand the current risk tolerance of the enterprise with respect to information and device security.
- Understand the security threats and potential damages to information, devices, and individuals.
- Create and follow policies and procedures that keep cyberattack risk and damages at or below a tolerable level.
- Effectively and efficiently detect and deal with cyberattack incidents.

Ensuring security in EIT has been made even more pressing and more difficult by the proliferation of mobile devices in enterprises and their ever-increasing use to conduct business. Increasingly, personal devices are used, accessing both corporate networks and public networks. The cost of mobile security incidents very easily can outweigh the cost of the mobile device itself.

Quality of Systems and Services

Typically, one of the primary responsibilities of the EIT organization is the timely provision of accurate and relevant information to the larger organization. While the EIT organization itself may not be responsible for creating the data, it is usually responsible for the data's physical and logical validity and integrity central to constructing information. It is for this reason that defining and using appropriate processes is essential to ensure high-quality operation, including the development or acquisition, implementation and integration of new or changed capabilities.

The EITBOK details the quality concepts of:

- How to approach measuring quality
- The importance of quality in requirements management
- Understanding an organization’s quality capability
- The differences between quality management systems, quality control, and quality assurance
- Cost of quality in technical debt and the cost of rework

Disaster Preparedness

As explained in the EITBOK, disaster preparedness and disaster recovery support business-continuity planning and include planning for EIT resiliency, as well as recovery from adversity, so that critical business services affected are restored to a satisfactory working state within an acceptable timeframe after an event. The EITBoK devotes a chapter to how the EIT organization and its parent must plan in advance for how it will provide sufficient organizational resilience to recover from disasters and return to normal operation as rapidly as possible. It provides the following examples of disasters and service interruptions that could occur and should be considered in prevention and recovery planning:

- Natural disaster affecting datacenters or EIT service operations (flood, fire, earthquake, wind)
- Security breach resulting in a disaster (destruction of data, admin password changes, virus/malware installation, sabotage)
- Usage error (accidental deletion, unplug/turn off system resulting in corruption)
- Utility failure affecting datacenters (loss of power even after UPS)
- Vendor failure (cloud provider security failure, oil spill)
- Staffing issue (employment dispute/walkout, epidemic)

These are examples of unpreparedness:

- Requiring use of computers or printers when power is out
- Requiring use of Internet when power or connectivity is out
- Single point of knowledge/control for administration access
- Lack of offsite backup storage
- Lack of working restoration from backups
- Lack of failover datacenters in separate locations
- Undocumented or out-of-date documentation for system interfaces
- Requiring use of phones that are out of power
- Lack of designation of leaders in restoration efforts (who is in charge of restoring service and they know they are in charge)
- In general, no cohesive, comprehensive EIT service restoration plan

Operations and Support of Delivered Systems and Services

Operations engineering is responsible for the operation of the system. SE is responsible for bringing together the needed experts to insure proper evaluation of proposed changes/upgrades to the system capabilities. It is difficult in some organizational structures to understand how to access requisite information quickly, and what information to share and how to share it. Decisions often must be made quickly, such as when a system is down. Decision effectiveness depends on involving the right decision-makers with a sufficiently complete understanding of the decision context and of criticality of the decision need.

In Operations and Support of deployed technologies, SE is still essential as the overall system of systems goes through maintenance upgrades, new application additions, obsolescence driven re-designs, etc. In addition, during decommissioning and disposal, SE is essential to deal with the proper decoupling of the system and ensuring conformance with policy and laws affecting the system disposal.

Operations and support activities focus on maintaining a normal state of operations in EIT environments, where systems and processes execute according to expectations, with no surprises to users. Normal states can be disrupted either by the expected and planned transition of an asset, or by an unexpected event, be it as large as a disaster or by the discovery of a system defect. In the former case, if there is a disaster recovery plan, it is executed; in the latter, incident management kicks in when a system halts, or problem management is exercised when an operational system is not functioning as expected.

ISO/IEC/IEEE 20000, the International Standard for Service Management (ISO/IEC 2018) may be used by an organization to develop and manage EIT operations, along with complementary information for the operations and infrastructure side of IT, such as the Information Technology Infrastructure Library (ITIL) (Axelos n.d.).

Ethics

Both the IEEE and ACM require their members to adhere to codes of ethics. (IEEE 2020, ACM 2018) In addition, the IEEE Computer Society and the ACM worked together on the Software Engineering Code of Ethics. (ACM/IEEE 1997)) Systems engineers in INCOSE have their own code as well. (INCOSE n.d.) All of these codes of ethics are somewhat different in style and length, but serve the same basic purpose.

Per the EITBOK, an EIT organization should create an easily accessible Code of Ethics:

- Ethical assertions should be documented and socialized in EIT in the form of a Code of Ethics, tied to the overall business code of ethics, and signed off by all staff so that violations can be cause for reprimand or dismissal.
- Vendors should be held to similar ethical standards.
- Lists of employees who have signed off on the Code of Ethics should be maintained through EIT governance practices.

The EITBOK has identified EIT ethical topics that include:

- Those actions and decisions that may be illegal
- Consideration of the social impact of the work at hand—if it will cause harm
- Alignment of business and EIT strategies and policies to an ethical standard
- Incorporation of the ideals of professionalism
- Adherence to applicable regulatory intent
- Protection for whistle blowers

Areas to specifically highlight:

- Activities that interfere with or corrupt the proper function of computers, applications and systems
- Activities that interfere with digital privacy or intellectual rights of others
- Respect for confidentiality, privacy, permissions, and access rights
- Inappropriate bias (skewing) of analysis and reporting
- Inaction in the face of likely ethics violations

EIT Roles

Major EIT systems have been disrupted and taken far too long to remedy due to the lack of information flow through the organization. Particularly for large systems, support activities are highly diverse in the roles people play, the technical knowledge required to build and install systems, to deal with downed systems, and in the organizational structure and culture in which people operate.

The roles range across the business functions requesting and supported by Enterprise technology, the evaluators, designers and implementers of those technologies, those who manage the successful transition of new systems into operation and manage and run the technology systems, to those who manage the quality of systems and services via defect reporting and tracking and who interface directly with end users.

Later sections will provide information about some major international models for defining EIT skills and capabilities.Accomplishing the EIT organization's mission requires people filling many roles ranging from enterprise architect, configuration manager, product designer, financial manager, and product manager. SE activities orchestrate the work of these roles so that they function together, rather than in silos or at cross purposes. Just as a systems engineer can play several roles in a given project, so might several people in an EIT project combine to fulfill the SE function. Larger EIT organizations may have many people performing SE functions and SE may be integrated into the EIT organization in many different ways depending on size, culture, organizational mission, and

any number of other factors. Part 5 of the SEBoK on Enabling Systems Engineering explores how systems engineering is woven into various organizations including EIT organizations.

Examples of Systems Engineering in EIT

SE provides a holistic discipline for integrating and managing the contributions of all roles needed to establish and provide EIT products and services. For her doctoral dissertation, Diane Aloisio from Purdue University performed a survey and causal analysis of project failures and of accidents. Aspects of the dissertation were published as a conference paper in Aloisio et al. (2018). The results were similar to those found in reviews of IBM consulting projects in the 1990s.

The following are examples of Systems Engineering interventions that prevented project failures in EIT systems. Almost all point to the lack of the System Engineering balancing act needed for product delivery.

- A widely used document processing product was undergoing a major upgrade. The new VP of Engineering wanted a project review before committing to a schedule. The review showed that the proposed schedule only considered the development effort and did not give sufficient weight to the voices of the testing and documentation organizations, while the needs of the tech support group had been completely overlooked. By establishing an integrated product management team that included technical expertise, as well as expertise in work breakdown and estimating, a realistic effort was defined and the resulting 9-month schedule was met within 3 weeks.
- A Silicon Valley start-up was depending entirely on an offshore development effort to produce its first product. All senior management was in the U.S. The VP of engineering made monthly visits to the development team. The CEO began to feel uneasy about the team's ability to deliver on schedule sensing that a lot of finger pointing within the development team itself signaled problems. There was no SE or IPT guiding the project. The VP of Engineering seemed unable to sort things out. A project review showed that the probable delivery date was at least 6 months beyond what the CEO was being told. The project was shut down.
- A major player in Human Resource Management had made commitments to deliver a new product. The project involved more than 100 people across the U.S. The delivery date kept slipping. Project roll-out would involve both installation of software and hardware at client sites, as well as installation and staff training at the large, centrally located Client Services organization. Executive Management needed to decide whether to reorganize this very expensive effort or cancel it. Again, the successful solution depended on establishing an effective cross-functional team (IPT) that necessarily included representatives from the technical teams. The IPT was supported by a newly established Project Management Office (PMO). The PMO integrated the geographically disparate efforts by establishing communication channels, as well as common estimating and scheduling practices. The PMO also instituted monthly critical metrics reports to show the IPT bottlenecks and inefficiencies across the project, from development efforts to Client Services set-up to Payroll technical support.

Systems Engineering provides a holistic discipline for integrating and managing the contributions of all of the roles needed to provide EIT products and services. It ensures that a single perspective does not dominate outcomes.

Key External Models of EIT Organizational Capability and Maturity

Because EIT is critical to businesses globally, considerable effort has gone into establishing universal frameworks for EIT skills, along with definitions of levels of capability of each skill. In addition, at least 2 models have been developed for evaluating the organizational performance of EIT. The effectiveness of systems engineering is key to the effectiveness of the EIT organization.

IT-CMF: IT-Capability Maturity Framework

The IT-CMF had its origin in a quality improvement effort at Intel Labs Europe in Ireland. Its intent, as described at the CIO Index website was to quantify and demonstrate the true value impact of IT. (CIO Index n.d.) IT-CMF is used to measure, develop, and monitor an organization's EIT capability maturity. It consists of 35 EIT management capabilities organized into four macro capabilities: managing EIT like a business; managing the EIT budget; managing the EIT capability; and managing EIT for business value. Its 35 critical capabilities are described in the EITBOK as "A defined EIT management domain that helps mobilize and deploy EIT-based resources to effect a desired end, often in combination with other resources and capabilities".

CMMI: Capability Maturity Model Integration (US)

The CMMI had its origin at the Software Engineering Institute in 1987 in a model requested by the U.S. Department of Defense for determining the capability maturity of contractor software development organizations. This became the Capability Maturity Model (CMM). Since then, it has been expanded into a set of Capability Maturity Models, all based on five levels of demonstrably increasing maturity as measured by organization performance. That set was then integrated and became the CMMI. The CMMI set addresses development, services, supplier management, people management, and data management. (CMMI Institute. n.d.)

SFIA: Skills Framework for the information Age (Europe, Canada and US)

The SFIA Framework has been downloaded and used by organizations and individuals in nearly 180 countries and is overseen by the SFIA Foundation (SFIA n.d.) It identifies 97 professional skills across EIT and supporting areas with seven levels of responsibility, which provide generic levels of responsibility, taking into account reflect experience and competency. These describe the behaviors, values, knowledge, and characteristics that an individual should have in order to be considered competent at a particular level.

E-CF: European Competency Framework (EU)

The ECF was the first sector-specific implementation of the European Qualifications Framework. The European Norm (EN) 16234-1 European e-Competence Framework (e-CF) provides a reference of 41 competences as applied at the Information and Communication Technology workplace, using a common European reference for competences, skills, knowledge and proficiency levels. The e-CF Explorer web tool is hosted by IT Professionalism Europe (ITPE n.d.).

I Competency Dictionary: EIT skills as Defined by METI/ IPA (Japan)

The Japanese government's Information-Technology Promotion Agency (IPA), established by the Ministry of Economy, Trade and Industry (METI) developed the "I Competency Dictionary" (iCD) to support the IT Engineers Examination. It underlies the METI/IPA Skills Standards for IT Professionals, abbreviated as ITSS, established in 2002. ITSS organizes skills within the information services industry into 11 job categories and 35 specialty fields. In each field, there are seven levels of competence based on individual experience and ability to perform. One appealing feature of ITSS is that this standard allows engineers to draw roadmaps for their own futures and career advancement. Approximately 90% of large enterprises and over 60% of SMEs in Japan have introduced or are

considering using ITSS. Information in English is available at https://www.ipa.go.jp/en/index.html.

International Standards Guiding EIT

The following standards guide the EIT community:

- ANSI/AIAA. 2012. *ANSI/AIAA Guide to the Preparation of Operational Concept Documents.* ANSI/AIAA G-043A-2012e
- IEEE 2012 Std 828™-2012, *IEEE Standard for Configuration Management in Systems and Software Engineering*
- ISO 10004:2012, Quality management—Customer satisfaction—Guidelines for monitoring and measuring
- ISO 10007:2003, Quality management systems—Guidelines for configuration management
- ISO 18238:2015, Space systems—Closed loop problem solving management
- ISO/IEC 25010:2011 Systems and software engineering—Systems and software Quality Requirements and Evaluation (SQuaRE)—System and software quality models
- ISO/IEC 16350:2015, Information technology—Systems and software engineering—Application management
- ISO/IEC 19770-1:2012, Information technology—Software asset management—Part 1: Processes and tiered assessment of conformance
- ISO/IEC 20000-1:2011, (IEEE Std 20000-1:2013) Information technology—Service management—Part 1: Service management system requirements
- ISO/IEC 20000–2:2012, Information technology—Service management—Part 2: Guidance on the application of service management systems
- ISO/IEC TR 20000–10:2015, Information technology—Service management—Part 10: Concepts and terminology
- ISO/IEC TR 20000–11:2015, Information technology—Service management—Part 11: Guidance on the relationship between ISO/IEC 20000-1:2011 and related frameworks: ITIL®
- ISO/IEC TR 20000-12—Information technology—IT Service management—Part 12: Guidance on the relationship between ISO/IEC 20000-1:2011 and service management frameworks: CMMI-SVC®
- ISO/IEC/IEEE 14764-2006, Software Engineering—Software Lifecycle Processes—Maintenance
- ISO/IEC 15939:2007, Systems and software engineering—Measurement process
- ISO/IEC/IEEE 42010:2011, Systems and software engineering — Architecture description

Every system has a set of properties that are largely a function of the system as a whole rather than just its constituent parts. There are dozens of these properties such as security, reliability, safety, resistance to electromagnetic interference, usability, and resilience. This Knowledge Area (KA) describes many of the most important such properties and how they are realized. The vocabulary to talk about these properties is not standard. Alternatively, they are called *quality attributes, non-functional requirements, -ilities,* and *specialties.* In this KA, the term specialty engineering refers to the collective engineering of all quality attributes of a system.

Quality attributes are often interdependent rather than orthogonal; e.g. making a system more secure may make it harder to use but also safer. Increasing system reliability often requires using more expensive parts and adding redundant components. Hence, higher reliability often means higher cost to deliver a system – another system property. However, higher reliability might mean lower maintenance cost – another system property. A systems engineer typically makes many decisions and takes many actions with regard to system properties; e.g. specifying which properties are important for a particular system, stating how those properties will be measured, trading off conflicting properties, and verifying that a system has the specified properties. Barry Boehm (2016), as the lead for a project of the Systems Engineering Research Center [1], introduced an ontology to describe system quality attributes

as a way of enabling smarter tradeoffs between them and understanding the impact of those trades on cost. Also, see the article on Quality Management for more information on how these decisions and actions are managed. de Weck, et al. (2012) has a lengthy and insightful chapter on quality attributes (which they call *-ilities).*

Many consider specialty engineering to be a sub-discipline of SE itself; e.g. they consider security engineering, safety engineering, resilience engineering, etc. to be part of SE. Others consider them to be stand-alone disciplines in their own right with close ties to SE. Either way, their mastery is important to a system engineer. This KA includes topical articles on several specialty engineering disciplines. Some articles will treat the topic of the article as a sub-discipline of SE itself; others will treat it as a closely related but separate discipline. This disparity reflects both the diversity of opinions on this matter and the fact that SEBoK articles are written by a wide array of authors.

Topics

Each part of the SEBoK is divided into knowledge areas (KAs), which are groupings of information with a related theme. The KAs, in turn, are divided into topics. This KA contains articles on the following topics, shown in alphabetical order:

- A Framework for Viewing Quality Attributes from the Lens of Loss
- Human Systems Integration
- Manufacturability and Producibility
- System Adaptability
- System Affordability
- System Hardware Assurance
- System Reliability, Availability, and Maintainability
- System Resilience
- Resilience Modeling
- System Resistance to Electromagnetic Interference
- System Safety
- System Security

Over time, this KA will expand to add topical articles about other quality attributes.

Specialty Requirements

The systems engineering team must ensure that requirements about quality attributes (also called specialty requirements) are properly reviewed with regard to their impact on life cycle costs, development schedule, technical performance, and operational utility. For example, security requirements can impact operator workstations, electromagnetic interference requirements can impact the signal in the interfaces between subsystems, and mass-volume requirements may preclude the use of certain materials to reduce subsystem weight.

Engineering specialists audit the evolving design and resulting configuration items to ensure that the overall system performance also satisfies the specialty requirements. Including appropriate specialty engineers within each systems engineering team ensures that all specialty requirements are identified and balanced throughout the development cycle.

Integration of Specialty Engineering

Integration of specialty engineering into a project or program is, or should be, a major objective of systems engineering management. (Endler 2016, Kossiakoff et al. 2020) With properly implemented procedures, the rigor of the systems engineering process ensures participation of the specialty disciplines at key points in the technical decision-making process. Special emphasis on integration is mandatory because a given design could in fact be accomplished without consideration of these specialty disciplines, leading to the possibility of system ineffectiveness

or failure when an unexamined situation occurs in the operational environment.

For example, human factors considerations can contribute to reduced workloads and therefore lower error rates by operators in aircraft cockpits, at air-traffic consoles, or in nuclear reactor stations. Similarly, mean-time-to-repair features can significantly increase overall system availability in challenging physical environments, such as mid-ocean or outer space or in safety critical environments such as hospital intensive care units or in traffic control systems in city centers. Specialty engineering requirements are often manifest as constraints on the overall system design space. The role of systems engineering is to balance these constraints with other functionality in order to harmonize total system performance. The end goal is to produce a system that provides utility and effectiveness to the customer at an affordable price.

As depicted in Figure 1, systems engineering plays a leadership role in integrating traditional disciplines, specialty disciplines, and unique system product demands to define the system design. Relationships for this integration process are represented as interactions among three filters.

The first filter is a conceptual analysis that leverages traditional design consideration (structural, electronics, aerodynamics, mechanical, thermodynamics, etc.). The second filter evaluates the conceptual approach using specialty disciplines, such as safety, affordability, quality assurance, human factors, reliability and maintainability, producibility, packaging, test, logistics, and others, to further requirements development. Design alternatives that pass through these two processes go through a third filter that incorporates facility design, equipment design, procedural data, computer programs, and personnel to develop the final requirements for design selection and further detailed development.

A Framework for Viewing Quality Attributes from the Lens of Loss

- Lead Author:
- John S. Brtis

-

Important but often under-considered areas of systems engineering address potential losses associated with the development and use of systems. These areas fall under the umbrella category of loss-driven systems engineering (LDSE), i.e., the value-adding unification of the systems engineering specialty areas that address the potential losses associated with systems. LDSE can be defined as an overarching systems engineering process which holistically addresses the quality characteristics concerned with loss (such as system resilience, system safety, and system security).

Overview

Systems engineering methodologies often focus on the delivery of desired capability. Methodology sources such as the Systems Engineering Handbook (Walden 2015) and ISO/IEC/IEEE 15288 (ISO) provide full lifecycle and fully integrated methodologies that focus on the generation and deployment of a system to deliver capabilities. Those methodologies are largely capability-driven and do not provide detailed fully integrated attention to potential loss. Loss and loss-driven specialty areas are largely treated in isolation. Examples of loss-driven specialty areas include resilience, safety, security, operational risk, environmental protection, quality, and availability. There is commonality and synergy among these specialty areas, which should be addressed by systems engineering. Potential synergies include:

- Shared loss scenarios
- Shared requirements
- Shared modeling and analysis techniques
- Shared architecture and design solutions
- Shared risk management

The expected benefits of applying a unified loss-driven viewpoint in the systems engineering processes include:

- Reducing engineering effort by eliminating redundant efforts among the specialty areas
- Helping to ensure a comprehensive consideration of loss
- Ensuring cohesion and elimination of conflicts among the loss-driven solutions
- Identifying highly effective solutions that address the interests of multiple loss-driven specialty areas
- Providing a holistic viewpoint addressing the multiple perspectives
- Reducing the load of data generated by multiple specialty areas to a minimal, non-redundant set
- Mutual learning among the loss-driven specialty areas

Background and Origins

Engineers at the MITRE Corporation explored the commonality of “protecting against loss” in the areas of security, safety, and resilience as part of an effort to improve a sponsor’s systems engineering methodologies (Brtis 2020). In parallel, these engineers raised and explored the issue with the INCOSE resilience and security working groups. This led to the realization that these specialty areas had commonalities and synergies with many of the systems engineering specialty areas. The term “loss-driven systems engineering” was coined to identify this area of common interest. These concepts were discussed with the INCOSE Technical Operations Director at the 17th INCOSE International Symposium, and he recommended that the concept be pursued as an INCOSE initiative. An exploratory

meeting on LDSE was held at the 18th INCOSE International Symposium. At that meeting participants agreed that this concept should be pursued and decided that as a first step, a special theme issue on loss-driven systems engineering of INCOSE *Insight* magazine should be pursued, to be followed by a section in the SEBoK. That issue of *Insight* was published in December 2021.

The Basis of Commonality

Systems engineering must address all loss-driven specialty areas in a mutually supportive and optimized manner. The exact definitions and demarcation between the different specialty areas are moot. What matters is meeting all the objectives of the loss-driven areas. Loss-driven areas often have common objectives, common concepts and principles, common requirements, common architectural solutions, common design solutions, common analyses, and common methodologies. Engineers responsible for loss-driven areas can often do a better job if they work collaboratively. This is because they are all interested in the same overarching concern: addressing potential losses associated with the system of interest. An inspection of the Systems Engineering Handbook (Walden 2015) identified specialty engineering areas that shared the concerns of loss-driven systems engineering. Those identified include:

- availability
- environmental impact
- maintainability
- resilience engineering
- reliability
- risk management
- system safety engineering
- system security engineering
- quality management

Attributes Shared by the Loss-Driven Specialty Areas, a Potential for Unification

The loss-driven specialty areas share attributes that specify the scope of each specialty area. All the loss-driven specialty areas have as attributes:

- the types of assets considered
- the types of loss addressed
- the types of adversity addressed
- the coping strategies considered
- the aspects of the system and its environment under consideration

These attributes define the scope of each specialty area. These scopes differ among the loss-driven specialty areas, but in many cases, they overlap. These loss-driven attributes and the possibility of aggregating their overall values provide a basis for integrating the loss-driven specialty areas, by aggregating the range of values of the parameters and then by addressing their aggregate scopes. Brtis (2020) considers each of these attributes. Figure 1 provides an aggregate summary of the scope of considerations identified for loss-driven attributes. Properly engineering a system requires consideration of the full range of each of the loss-driven attributes.

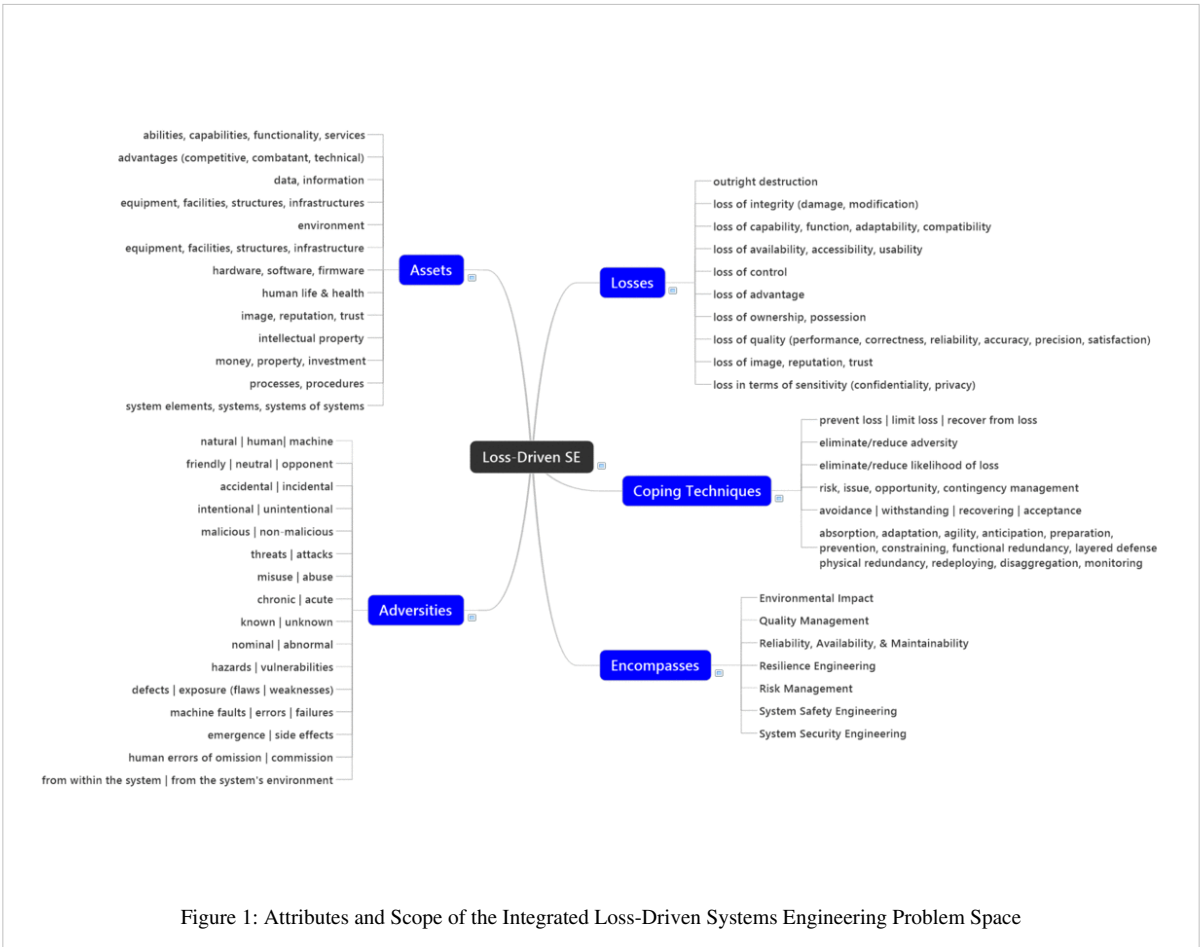

Figure 1: Attributes and Scope of the Integrated Loss-Driven Systems Engineering Problem Space

Core Principles for LDSE

Winstead (2020) investigated the commonality among principles being articulated for individual loss-driven specialty areas. He identified fundamental principles that can be unified across the specialties.

- Candidate principle 1: Systems engineering minimizes hazards.
- Candidate principle 2: Systems engineering seeks to control hazards that cannot be avoided, including assuring transitions from one known acceptable mode or state to another known and acceptable one.
- Candidate principle 3: Systems engineering uses proven and accepted processes, solutions, methods, materials, etc. when the process, etc., achieves the intended trustworthiness.
- Candidate principle 4: The human within the system should be enabled to prevent, minimize, and recover from loss when possible.
- Candidate principle 5: Systems engineering should strive for the simplest solutions.
- Candidate principle 6: Systems engineering produces evolvable systems likely to maintain or improve on loss-driven properties through change.
- Candidate principle 7: Actions should trace to the entity responsible.
- Candidate principle 8: Any critical task should be possible to perform in more than one way.

Winstead (2020) also considered the systems engineering principles of Watson (2019) and discusses minimal changes needed to make them well-suited for application to loss-driven systems engineering.

LDSE in the SE Activities

Brtis (2020) found that several the SE practices identified in ISO 15288 and the INCOSE SE Handbook need to be augmented to adequately address the needs of LDSE and recommended specific additions for the following practice areas:

- Business or Mission Analysis Process
- Stakeholder Needs and Requirements Definition Process
- System Requirements Definition Process
- Architecture Definition Process
- Design Definition Process
- Risk Management Process

LDSE Design Techniques

Winstead (2021) investigates what he calls “loss control” for cyber-physical systems. He investigates loss control independent of any particular systems engineering specialty area. He recommends a set of loss control design principles:

- ***Anomaly Detection*** - Any salient anomaly in the system or in its environment is detected in a timely manner that enables effective response action.
- ***Commensurate Protection*** - The strength and type of protection provided to an element must be commensurate with the most significant adverse effect that results from a failure of that element.
- ***Commensurate Response*** - The design should match the aggressiveness of an engineered response action’s effect to the needed immediacy to control the effects of each loss scenario.
- ***Continuous Protection*** - The protection provided for an element must be effective and uninterrupted during the time that the protection is required.
- ***Defense-in-depth*** - Loss is prevented or minimized by employing multiple coordinated techniques and strategies.
- ***Distributed Privilege*** - Multiple authorized entities must act in a coordinated manner before an operation on the system is allowed to occur.
- ***Diversity (Dynamicity)*** - The design delivers the required capability through structural, behavioral, data, or control flow variation.
- ***Domain Separation*** - Domains with distinctly different protection needs should be physically or logically separated.
- ***Least Functionality*** - Each element should have the capability to accomplish its required functions, but no more.
- ***Least Persistence*** - System elements and other resources should be available, accessible, and able to fulfill their design intent only for the time they are needed.
- ***Least Privilege*** - Each element should be allocated privileges that are necessary to accomplish its specified functions, but no more.
- ***Least Sharing*** - System resources should be shared among system elements only when necessary, and among as few system elements as possible.
- ***Loss Margins*** - The system is designed to operate in a state space sufficiently distanced below the threshold at which loss occurs.
- ***Mediated Access*** - All access to and operations on system elements are mediated.
- ***Protective Defaults*** - The default configuration of the system provides maximum protection effectiveness.
- ***Protective Failure*** - A failure of a system element should neither result in an unacceptable loss, nor invoke another loss scenario.
- ***Protective Recovery*** - The recovery of a system element should not result in, nor lead to, unacceptable loss.
- ***Redundancy*** - The design delivers the required capability by the replication of functions or elements.

Technical Management Considerations

The effective coordination and management of LDSE specialty areas – areas that have often operated independently and in isolation of one another – poses a challenge. Jackson (2020) discusses the concept of siloism in the context of LDSE projects and ways to mitigate that effect. Siloism is the unwillingness of members of any team to share information. Failure to mitigate siloism can reduce the effectiveness of the entire team. Jackson recommends mitigating siloism using integrated product teams (IPTs), which utilize organizational structure and rigorous management to encourage sharing of information among specialties. Brtis (2021) suggests that for LDSE the systems engineer should holistically consider:

- the full spectrum of adversities
- the full spectrum of weaknesses, defects, flaws, exposures, hazards, and vulnerabilities
- the full spectrum of assets and losses
- the full spectrum of timeframes of interest
- the full spectrum of coping mechanisms

and further, suggests the systems engineer:

- elicit, analyze, and capture loss-driven requirements as part of the overall stakeholder and system requirements development
- make the loss-driven architectural decisions holistically across the loss-driven specialty areas
- make the loss-driven design decisions holistically across the loss-driven specialty areas
- integrate the management of risks associated with all loss-driven areas

Endler (2021) considers real life integration of loss-driven systems engineering activities into system development activities. Challenges identified include lack of appreciation of the importance of loss-driven systems engineering activities and organizational barriers. He finds that existing systems engineering standards poorly describe loss-driven systems engineering activities and fail to integrate loss-drive activities with traditional engineering activities. He proposes methods to overcome those barriers based on widely accepted standards. He offers an approach to accomplish the needed integration with emphasis on the need that loss-driven systems engineers participate throughout the system life cycle and be supported by a common understanding of an integrated approach.

Consequences for Model-Based Systems Engineering

Model-based systems engineering data and models need to be augmented to address the shared attributes of loss-driven systems engineering: assets, losses, adversities, and coping techniques and the common information artifacts identified above. Table 1 identifies some of the additional modeling information (in SysML form) that needs to be captured during the various lifecycle stages to support the effective development and documentation of loss management scenarios and loss management requirements.

Table 1. Modeling Information and Artifacts During Lifecycle Phases (Brtis 2020)

Lifecycle Phase	Artifacts and Information
Mission and Stakeholder Needs Analysis	Add adversities to the context diagram as actors • Add loss management scenarios as use cases
Stakeholder Requirements	Develop use case interaction diagrams to document the interaction of actors and architectural modules during the loss management scenarios • Develop sequence diagrams to represent the activity flow during loss management scenarios
System Requirements	Develop activity diagrams to show the states of the system (and adversities) during loss management scenarios
Architecture and System Design	Develop state models of the loss management scenarios • Model events and signals among the architectural nodes

System Design	Propose and select loss management design features • Document loss management related object distribution

Use Case: Manned Space Rescue Vehicle

Cureton (2020) explores the applicability of LDSE to a use case, a hypothetical manned space rescue vehicle, via a thought experiment regarding desirable characteristics for achieving resilience, safety, reliability, security, and other loss-driven goals. Various design reference missions are explored for assessment of required loss-driven capabilities in automated flight operations for a hypothetical manned space rescue vehicle.

Summary

Loss-driven systems engineering offers a valuable unification of loss-driven systems engineering specialty areas. Applying this can integrate currently isolated systems engineering activities, leading to improved system effectiveness and reduced systems engineering costs, while improving the management of potential losses associated with the development and use of systems.

Human Systems Integration

- Lead Authors:
- Ben Schwartz and Holly Handley
- Contributing Authors:
- Guy Boy, Alice Squires, Paul Phister, Stuart Booth, and Dick Fairley

-

Human systems integration (HSI) is "the management and technical discipline of planning, enabling, coordinating, and optimizing all human-related considerations during system design, development, test, production, use and disposal of systems, subsystems, equipment and facilities." (SAE 2019).

Though used by industries around the world, HSI was initiated by the U.S. Department of Defense (DoD) as part of the "total system approach" to acquisition. The goal of HSI is to "optimize total system performance (hardware, software, and human), operational effectiveness, and suitability, survivability, safety, and affordability." (DoD 2003.) This article itself focuses on HSI within the DoD, although much of it is applicable to other government and commercial organizations worldwide.

HSI activities must be initiated "early in system development (during stakeholder requirements generation) and continuously through the development process to realize the greatest benefit to the final system solution and substantial life cycle cost savings." (INCOSE 2015).

HSI generally incorporates the following seven domains as integration considerations (although some organizations may use a slightly different set): manpower, personnel, training, human factors engineering, safety and occupational health, force protection and survivability, and habitability.

Overview

Historically, insufficient systems engineering resources were dedicated to ensuring proper integration of humans with the rest of the system. Most projects were technology-centered with human considerations being addressed through training. Technological systems were hard to use and maintain resulting in large manpower and training costs, reduced system performance, and increased risk of catastrophic loss, among other impacts.

The U.S. Army was among the first to address this with the Manpower and Personnel Integration (MANPRINT) program in 1986. MANPRINT emphasized the consideration of the HSI domains throughout the system acquisition as a standard part of the systems engineering effort. The approach has since been adopted by the broader DoD, by other militaries, and by civilian government agencies around the world. (Booher 2003). Some organizations, particularly the U.K. Ministry of Defence, use the term Human Factors Integration (HFI).

HSI applies systems engineering processes, tools, and techniques to ensure that human considerations are given proper weight in all system development activities. HSI should not be confused with Human Factors Engineering (HFE); HFE is a domain of HSI focusing on designing human interfaces. HSI is about mutual integration of technology, organizations, and people.

System Description

HSI is more than human factors, human-computer interaction, or systems engineering. It is a technical and managerial set of processes that involves the consideration and integration of multiple domains. In addition, HSI involves complexity analysis and organization design and management. Various organizations represent the HSI domains differently as the number and names of the domains are aligned with existing organizational structures. Booher (2003) first presented the original seven US Army domains as manpower, personnel, training, human factors engineering, soldier survivability, system safety and health hazards. Other countries may have a different number of domains with slightly different names, however, all the technical work of the domains is present. For example, the UK Defence Standard (00-251) includes seven similar domains: manpower, personnel, health hazards, training, human factors engineering, social/ organizational and system safety. The seven domains used across the DoD Instruction (DoD 2017) that tells how to operate the DoD Acquisition System are as follows:

1. **Manpower** Determining the most efficient and cost-effective mix of manpower and contract support necessary to operate, maintain, provide training and support the system. Manpower describes the number and mix of personnel required to carry out a task, multiple tasks, or mission in order to operate, maintain, support, and provide training for a system. Manpower factors are those variables that define manpower requirements. These variables include job tasks, operation/maintenance rates, associated workload, and operational conditions (e.g., risk of operator injury) (DAU 2010).
2. **Personnel:** Determining and selecting the appropriate cognitive, physical, and social capabilities required to train, operate, maintain, and sustain systems based on available personnel inventory or assigned to the mission. Personnel factors are those human aptitudes (i.e., cognitive, physical, and sensory capabilities), knowledge, skills, abilities, and experience levels that are needed to properly perform job tasks. Personnel factors are used to develop occupational specialties for system operators, maintainers, trainers, and support personnel (DAU 2010). The selection and assignment of personnel is critical to the success of a system, as determined by the needs set up by various work-related requirements.
3. **Training:** Developing efficient and cost-effective options that enhance user capabilities and maintain skill proficiencies for individual, collective, and joint training of operators and maintainers. Training is the learning process by which personnel individually or collectively acquire or enhance pre-determined job-relevant knowledge, skills, and abilities by developing their cognitive, physical, sensory, and team dynamic abilities. The "training/instructional system" integrates training concepts and strategies, as well as elements of logistic support to satisfy personnel performance levels required to operate, maintain, and support the systems. It includes the "tools" used to provide learning experiences, such as computer-based interactive courseware, simulators, actual equipment (including embedded training capabilities on actual equipment), job performance aids, and Interactive Electronic Technical Manuals (DAU 2010).
4. **Human Factors Engineering:** The integration of human characteristics into system definition, design, development, and evaluation to optimize human-system performance under operational conditions. Human factors engineering (HFE) is primarily concerned with designing human-machine interfaces consistent with the physical, cognitive, and sensory abilities of the user population (DAU 2010). It focuses on ensuring that the system design is compatible with the human user. HFE considers required human tasks, and the sensory, perceptual, mental, and physical attributes of the user personnel who will operate, control, maintain, and support the equipment, system, or facility. The objective of HFE is to optimize human-system performance within the desired levels of life-cycle costs. HFE domain considerations span a wide range and include design and layout of working areas, user-equipment interfaces, use of automation and decision aids, and normal, non-normal, and emergency conditions.
5. **Safety & Occupational Health:** Consider environmental, safety and occupational health in determining system design characteristics to enhance job performance and minimize risks of illness, disability, injury and death to operators and maintainers. Safety considers the design features and operating characteristics of a system that serve to minimize the potential for human or machine errors or failure that cause injurious accidents (DAU 2010).

Safety also encompasses the administrative procedures and controls associated with the operations, maintenance, and storage of a system. Occupational health factors are those system design features that serve to minimize the risk of injury, acute or chronic illness, or disability, and/or reduce job performance of personnel who operate, maintain, or support the system. Prevalent issues include noise, chemical safety, atmospheric hazards (including those associated with confined space entry and oxygen deficiency), vibration, ionizing and non-ionizing radiation, and human factors issues that can create chronic disease and discomfort such as repetitive motion diseases. Many occupational health problems, particularly noise and chemical management, overlap with environmental impacts. Human factors stress that creating a risk of chronic disease and discomfort overlaps with occupational health considerations (DAU 2010).

6. **Force Protection & Survivability:** Impact system design (e.g., egress, survivability) to protect individuals and units from direct threat events and accidents, including chemical, biological, and nuclear threats. Force Protection and Survivability is the HSI domain that facilitates system operation and personnel safety during and after exposure to hostile situations or environments. Force protection refers to all preventive measures taken to mitigate hostile actions against personnel (to include family members), resources, facilities, and critical information. Survivability denotes the capability of the system and/or personnel manning the system to avoid or withstand manmade hostile environments without suffering an abortive impairment of his/her ability to accomplish its designated mission. Survivability factors consist of those system design features that reduce the risk of fratricide, detection, and the probability of being attacked, and that enable personnel to withstand man-made hostile environments without aborting the mission or objective, or suffering acute chronic illness, disability, or death. Survivability attributes are those that contribute to the survivability of manned systems (DAU 2010).
7. **Habitability:** Establishing and enforcing requirements for individual and unit physical environments, personnel services, and living conditions, to prevent or mitigate risk conditions that adversely impact performance, quality of life and morale, or degrade recruitment or retention. Habitability factors are those living and working conditions that are necessary to sustain the morale, safety, health, and comfort of the user population. They directly contribute to personnel effectiveness and mission accomplishment and often preclude recruitment and retention problems. Examples include lighting, space, ventilation, and sanitation; noise and temperature control (i.e., heating and air conditioning); religious, medical, and food services availability; and berthing, bathing, and personal hygiene. Habitability consists of those characteristics of systems, facilities (temporary and permanent), and services necessary to satisfy personnel needs. Habitability factors are those living and working conditions that result in levels of personnel morale, safety, health, and comfort adequate to sustain maximum personnel effectiveness, support mission performance, and avoid personnel retention problems (DAU 2010).

Discipline Management

In a contractor project organization, the human systems integrator is typically a member of the senior engineering staff reporting to either the systems engineering lead or chief engineer.

HSI activities are documented in the Systems Engineering Management Plan (SEMP). Larger programs may have a stand-alone HSI Plan (HSIP) compatible with and referenced by the SEMP. HSI activities are tailored to the needs of the project and the project life cycle (NASA 2016).

Most projects implement a Joint HSI Working Group between the customer and contractor. This enables sharing of priorities, knowledge, and effort to allow each group to achieve their objectives.

Discipline Relationships

Interactions

Interactions include:

- SE: HSI is an integral part of the systems engineering effort and the integrator participates in all relevant systems engineering activities during the whole life cycle of the system being considered.
- HSI domain experts: Domain experts collaborate with the human systems integrator to achieve HSI objectives, though this may or may not be a direct reporting relationship.
- The contractor and customer may each have a human systems integrator and various domain experts; each role should collaborate with their counterparts to the appropriate extent.
- HSI domain experts may participate in integrated product teams (IPTs)/design teams as full participants or consultants as appropriate for the needs of the project.
- HSI shares many concerns with Reliability, Availability, and Maintainability (RAM). The integrator and/or domain experts may collaborate with RAM specialists as appropriate.
- The integrator and/or domain experts should work with the Test & Evaluation team to ensure that HSI is represented in test and evaluation events.
- HSI shares many concerns with logistics and supportability, the integrator and/or domain experts may collaborate with this team as appropriate.

Dependencies

HSI depends on sufficient scope of work and authorization from the project. Proper planning and leadership buy-in is a key enabler.

Discipline Standards

Note: These are standards relevant to the practice of HSI specifically and not each of the HSI domains, which have their own standards and practices.

- U.S. Army. 2015. Regulation 602-2: Human Systems Integration in the System Acquisition Process. Washington: Headquarters, Department of the Army.
- U.S. Department of Defense. 2011. Data Item Description: Human Systems Integration Program Plan. DI-HFAC-81743A.
- U.S. Navy. 2017. Opnav Instruction 5310.23A: Navy Personnel Human Systems Integration. Washington: Office of the Chief of Naval Operations: Department of the Navy.

Personnel Considerations

HSI is conducted by a human systems integrator. The integrator is part of the systems engineering team responsible for conducting systems engineering related to human and organizational considerations and for coordinating the work of the HSI domain experts.

HSI uses the same techniques and approaches as systems engineering with additional consideration for non-materiel aspects of the system. Therefore, the integrator must be well-versed in the SE process and have a working understanding of each of the domains. The integrator does not need to be an expert in any of the domains.

The human systems integrator's responsibilities include:

- providing inputs to the SEMP and/or creating an HSI Plan (HSIP) compatible with the SEMP and the project life cycle (NASA Systems Engineering Handbook 2016)
- tailoring the scope of HSI efforts to the needs of the project and system life cycle
- ensuring HSI domains are given appropriate consideration across all programmatic and engineering activities
- assisting domain personnel in planning domain activities
- facilitating execution of domain tasks and collaboration among domains
- making tradeoffs among domains to optimize the attainment of HSI goals
- optimizing the impact of domains on the acquisition program from the perspectives of performance, sustainability, and cost
- integrating the results of domain activities and representing them to the rest of the acquisition program from a total HSI perspective
- facilitating interactions among domains within the scope of HSI, and between HSI and the rest of the program
- tracking, statusing, and assessing HSI risks, issues and opportunities that have surfaced during the execution of the program

Metrics

Human-System Measures of Effectiveness

A measure of effectiveness (MOE) is a metric corresponding to the accomplishment of the mission objective. MOEs measure system performance in a representative mission context, including with representative users. Effectiveness is typically achieved through a combination of hardware, software, and human components, thus there are not typically HSI-specific MOEs.

MOEs may be decomposed into measures of performance (MOP) and measures of suitability (MOS). There may be HSI-specific MOPs and MOSs. For example, an MOE for an air defense radar might be positive detection probability, with an MOP for the radar's effective resolution and an MOP for the operator's ability to identify the target. It is the human system integrator's responsibility to ensure that relevant MOPs and MOSs are identified and incorporated into modeling, simulation, test, and evaluation efforts. The integrator and domain experts may contribute to these efforts as appropriate.

Models

HSI Process Models

HSI shares common systems engineering models with general systems engineering; e.g. the SE Vee process model. Additionally, a number of HSI-specific models and processes exist. A particularly good resource is "A User-Centered Systems Engineering Framework" by Ehrhart and Sage (in Booher 2003).

Human Performance and Domain Models

A variety of human performance models exist for cognition, behavior, anthropometry, strength, fatigue, attention, situation awareness, etc. Additionally, a variety of models exist for each HSI domain. The integrator should have a good understanding of the types of models available and the appropriate applications. In a project utilizing model-based systems engineering, the system model should include humans. The integrator should ensure sufficient fidelity to meet the needs of the project. Human-in-the-loop simulations should be encouraged during the design process as during the whole life cycle of a product.

Tools

HSI shares common tools with systems engineering. A sample of HSI-specific tools include:

- Command Control and Communications - Techniques for Reliable Assessment of Concept Execution (C3TRACE) [1] developed by U.S. Army Research Labs.
- Comprehensive Human Integration Evaluation Framework (CHIEF) [2] developed by U.S. Navy.
- Human Analysis and Requirements Planning System (HARPS) [3] developed by U.S. Navy Space and Naval Warfare Systems Command.
- Human Systems Integration Framework (HSIF) [4] developed by U.S. Air Force. (USAF 2009)
- Improved Performance and Research Integration Tool (IMPRINT) [1] developed by U.S. Army Research Labs.

Additionally, each HSI domain has specific tools and approaches for their unique efforts and considerations.

Practical Considerations

Pitfalls

Many organizations assign a human factors engineer to the human systems integrator role. This can be a mistake if the individual is not well versed in the SE process. Relegating HSI to a “specialty engineering” team deprives the integrator of sufficient scope and authority to accomplish their mission.

Proven Practices

Ensure the human systems integrator is a knowledgeable systems engineer with the respect of the other systems engineers and with a good understanding of each of the HSI domains. A human systems integrator should be involved in program planning activities to ensure sufficient budget and schedule. They should be involved in technical planning activities to create sufficient scope in the SEMP/HISPP, identify HSI-related risks and opportunities, recommend HSI trade studies, etc. There is significant overlap and trade space among the HSI domains, therefore the domain experts, led by the integrator, should collaborate throughout the project to optimize the impact of HSI.

Manufacturability and Producibility

- Lead Authors:
- Dick Fairley and Kevin Forsberg
- Contributing Authors:
- Paul Phister, Alice Squires, and Richard Turner

-

Manufacturability and producibility is an engineering specialty. The machines and processes used to build a system must be architected and designed. A systems engineering approach to manufacturing and production is necessary because manufacturing equipment and processes can sometimes cost more than the system being built (Maier and Rechtin 2009). Manufacturability and producibility can be a discriminator between competing system solution concepts and therefore must be considered early in the study period, as well as during the maturing of the final design solution.

Overview

The system being built might be intended to be one-of-a-kind or to be reproduced multiple times. The manufacturing system differs for each of these situations and is tied to the type of system being built. For example, the manufacture of a single-board computer would be vastly different from the manufacture of an automobile. Production involves the repeated building of the designed system. Multiple production cycles require the consideration of production machine maintenance and downtime.

Manufacturing and production engineering involve similar systems engineering processes specifically tailored to the building of the system. Manufacturability and producibility are the key attributes of a system that determine the ease of manufacturing and production. While manufacturability is simply the ease of manufacture, producibility also encompasses other dimensions of the production task, including packaging and shipping. Both these attributes can be improved by incorporating proper design decisions that take into account the entire system life cycle (Blanchard and Fabrycky 2010).

System Affordability

- Lead Author:
- Paul Phister
- Contributing Author:
- Ray Madachy

-

According to MITRE (2014), affordability is the "ability to fund desired investment". "Solutions are affordable if they can be deployed in sufficient quantity to meet mission needs within the (likely) available budget." INCOSE (2015) offers a slightly deeper definition. A system is affordable to the degree that system performance, cost, and schedule constraints are balanced over the system life, while mission needs are satisfied in concert with strategic investment and organizational needs. Design for affordability is the practice of considering affordability as a design characteristic or constraint.

Increasing competitive pressures and the scarcity of resources demand that systems engineering (SE) improve affordability. Several recent initiatives have made affordability their top technical priority. They also call for a high priority to be placed on research into techniques — namely, improved systems autonomy and human performance augmentation — that promise to reduce labor costs, provide more efficient equipment to reduce supply costs, and create adaptable systems whose useful lifetime is extended cost-effectively.

However, methods for cost and schedule estimation have not changed significantly to address these new challenges and opportunities. There is a clear need for:

- new methods to analyze tradeoffs between cost, schedule, effectiveness, and resilience;
- new methods to adjust priorities and deliverables to meet budgets and schedules; and
- more affordable systems development processes.

All of this must be accomplished in the context of the rapid changes underway in technology, competition, operational concepts, and workforce characteristics.

Overview

Historically, cost and schedule estimation has been decoupled from technical SE tradeoff analyses and decision reviews. Most models and tools focus on evaluating either cost-schedule performance or technical performance, but not the tradeoffs between the two. Meanwhile, organizations and their systems engineers often focus on affordability to minimize acquisition costs. They are then drawn into the easiest-first approaches that yield early successes, at the price of being stuck with brittle, expensive-to-change architectures that increase technical debt and life cycle costs.

Two indications that the need for change is being recognized in systems engineering are that the *INCOSE SE Handbook* now includes affordability as one of the criteria for evaluating requirements (INCOSE 2015) and that there is a trend in SE towards stronger focus on maintainability, flexibility, and evolution (Blanchard, Verma, and Peterson 1995).

There are pitfalls for the unwary. Autonomous systems experience several hazardous failure modes, including:

- **system instability due to positive feedback —** where an agent senses a parameter reaching a control limit and gives the system a strong push in the other direction, causing the system to rapidly approach the other control limit, causing the agent (or another) to give it an even stronger push in the original direction, and so on
- **self-modifying autonomous agents which fail** after several self-modifications — the failures are difficult to debug because the agent's state has been changing
- **autonomous agents performing weakly at commonsense reasoning** about system control decisions by human operators, and so tend to reach incorrect conclusions and make incorrect decisions about controlling the system
- **multiple agents making contradictory decisions** about controlling the system, and lacking the ability to understand the contradiction or to negotiate a solution to resolve it

Modularization of the system's architecture around its most frequent sources of change (Parnas 1979) is a key SE principle for affordability. This is because when changes are needed, their side effects are contained in a single systems element, rather than rippling across the entire system.

This approach creates the need for three further improvements:

- refocusing the system requirements, not only on a snapshot of current needs, but also on the most likely sources of requirements change, or evolution requirements;
- monitoring and acquiring knowledge about the most frequent sources of change to better identify requirements for evolution;
- evaluating the system's proposed architecture to assess how well it supports the evolution requirements, as well as the initial snapshot requirements.

This approach can be extended to produce several new practices. Systems engineers can

- identify the commonalities and variability across the families of products or product lines, and develop architectures for creating (and evolving) the common elements *once* with plug-compatible interfaces for inserting the variable elements,;(Boehm, Lane, and Madachy 2010)
- extrapolate principles for service-oriented system elements that are characterized by their inputs, outputs, and assumptions, and that can easily be composed into systems in which the sources of change were not anticipated;
- develop classes of smart or autonomous systems whose many sensors identify needed changes, and whose autonomous agents determine and effect those changes in microseconds, or much more rapidly than humans can, reducing not only reaction time, but also the amount of human labor needed to operate the systems, thus improving affordability.

Personnel Considerations

Autonomous systems need human supervision, and the humans involved require better methods for trend analysis and visualization of trends (especially undesired ones).

There is also the need, with autonomous systems, to extend the focus from life cycle costs to total ownership costs, which encompass the costs of failures, including losses in sales, profits, mission effectiveness, or human quality of life. This creates a further need to evaluate affordability in light of the value added by the system under consideration. In principle, this involves evaluating the system's total cost of ownership with respect to its mission effectiveness and resilience across a number of operational scenarios. However, determining the appropriate scenarios and their relative importance is not easy, particularly for multi-mission systems of systems. Often, the best that can be done involves a mix of scenario evaluation and evaluation of general system attributes, such as cost, schedule, performance, and so on.

As for these system attributes, different success-critical stakeholders will have different preferences, or utility functions, for a given attribute. This makes converging on a mutually satisfactory choice among the candidate system solutions a difficult challenge involving the resolution of the multi-criteria decision analysis (MCDA) problem among the stakeholders (Boehm and Jain 2006). This is a well-known problem with several paradoxes, such

as Arrow's impossibility theorem that describes the inability to guarantee a mutually optimal solution among several stakeholders, and several paradoxes in stakeholder preference aggregation in which different voting procedures produce different winning solutions. Still, groups of stakeholders need to make decisions, and various negotiation support systems enable people to better understand each other's utility functions and to arrive at mutually satisfactory decisions, in which no one gets everything that they want, but everyone is at least as well off as they are with the current system.

Also see System Analysis for considerations of cost and affordability in the technical design space.

This article describes the discipline of hardware assurance, especially as it relates to systems engineering. It is part of the SE and Quality Attributes Knowledge Area.

Overview

System hardware assurance is a set of system security engineering activities (see System Security for more information) undertaken to quantify and increase the confidence that electronics function as intended and only as intended throughout their life cycle, and to manage identified risks. The term *hardware* refers to electronic components, sometimes called integrated circuits or chips. As products of multi-stage processes involving design, manufacturing and post-manufacturing, packaging, and test, they must function properly under a wide range of circumstances. Hardware components – alone and integrated into subcomponents, subsystems, and systems – have weaknesses and vulnerabilities enabling exploitation. Weaknesses are flaws, bugs, or errors in design, architecture, code, or implementation. Vulnerabilities are weaknesses that are exploitable in the context of use (Martin 2014).

Hardware assurance is conducted to minimize risks related to hardware that can enable adversarial exploitation and subversion of functionality, counterfeit production, and loss of technological advantage. Challenges include increasing levels of sophistication and complexity of hardware architectures, integrated circuits, operating systems, and application software, combined with supply chain risks, emergence of new attack surfaces, and reliance on global sources for some components and technologies.

After identifying concerns and applicable mitigations, hardware assurance offers a range of possible activities and processes. At the component level, hardware assurance focuses on the hardware itself and the supply chain used to design and manufacture it; at the subcomponent, subsystems, and system levels, hardware assurance incorporates the software and firmware integrated with the component.

Engineering efforts to enhance trust in hardware have increased in response to complex hardware architectures, the increasing sophistication of adversarial attacks on hardware, and globalization of supply chains. These factors raise serious concerns about the security, confidentiality, integrity, and availability as well as the provenance and authenticity of hardware. The “root of trust” (NIST 2020) of a system is typically contained in the processes, steps, and layers of hardware components and across the systems engineering development cycle. System hardware assurance focuses on hardware components and their interconnections with software and firmware to reduce risks to proper function or other compromises of the hardware throughout the complete life cycle of components and systems. Advances in hardware assurance tools and techniques will strengthen designs, and enhance assurance during manufacturing, packaging, test, and deployment and operational use.

Life Cycle Concerns of Hardware Components

Hardware assurance should be applied at various stages of a component's life cycle from hardware architecture and design, through manufacturing and testing, and finally throughout its inclusion in a larger system. The need for hardware assurance then continues throughout its operational life including sustainment and disposal.

As semiconductor technology advances the complexity of electronic components, it increases the need to "bake-in" assurance. Risks created during architecture, design, and manufacturing are challenging to address during the operational phase. Risks associated with interconnections between and among chips are also a concern. Therefore, improving a hardware assurance posture must occur as early as possible in the life cycle, thereby reducing the cost and schedule impacts associated with "fixing" components later in the life cycle of the system.

A conceptual overview of the typical hardware life cycle (Figure 1) illustrates the phases of the life cycle of components, as well as the subsystems and systems in which they operate. In each phase multiple parties and processes contribute a large set of variables and corresponding attack surfaces. As a result, the potential exists for compromise of the hardware as well as the subcomponents and systems in which they operate; therefore, matching mitigations should be applied at the time the risks are identified.

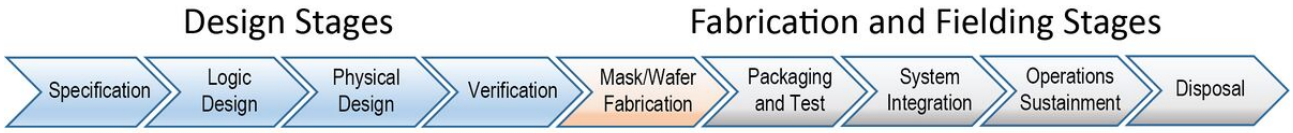

Figure 1. Component Life Cycle. (SEBoK Original)

Both the value of the hardware component and the associated cost of mitigating risks increase at each stage of the life cycle. Therefore, it is important to identify and mitigate vulnerabilities as early as possible. It takes longer to find and fix defects later, thereby increasing the complexity of replacing hardware with "corrected" designs that create system integration issues. In addition to cost savings, early correction and mitigation avoid delays in creating an operational system. It is essential to re-assess risks associated with hardware components throughout the life cycle periodically, especially as operational conditions change.

Hardware assurance during system sustainment is a novel challenge given legacy hardware and designs with their associated supply chains. In long-lived high-reliability systems, hardware assurance issues are compounded by obsolescence and diminished sourcing of components, thereby increasing concerns related to counterfeits and acquisitions from the gray market.

Function as Intended and Only as Intended

Exhaustive testing can check system functions against specifications and expectations; however, checking for unintended functions is problematic. Consumers have a reasonable expectation that a purchased product will perform as advertised and function properly (safely and securely, under specified conditions) – but consumers rarely consider if additional functions are built into the product. For example, a laptop with a web-conferencing capability comes with a webcam that will function properly when enabled, but what if the webcam also functions when turned off, thereby violating expectations of privacy? Given that a state-of-the-art semiconductor component might have billions of transistors, "hidden" functions might be exploitable by adversaries. The statement "function as intended and only intended" communicates the need to check for unintended functions.

Hardware specifications and information in the design phase are needed to validate that components function properly to support systems or missions. If an engineer creates specifications that support assurance that flow down the system development process, the concept of "function as intended" can be validated for the system and mission through accepted verification and validation processes. "Function only as intended" is also a consequence of capturing the requirements and specifications to assure the product is designed and developed without extra

functionality. For example, a Field Programmable Gate Array (FPGA) contains programmable logic that is highly configurable; however, the programmable circuitry might be susceptible to exploitation.

Given the specifications of a hardware component, specialized tools and processes can be used to determine with a high degree of confidence whether the component's performance meets specifications. Research efforts are underway to develop robust methods to validate that a component does not have capabilities that threaten assurance or that are not specified in the original design. Although tools and processes can test for known weaknesses, operational vulnerabilities, and deviations from expected performance, all states of possible anomalous behavior cannot currently be determined or predicted.

Data and information can be used to validate the component's function and should be collected from multiple sources including designers, developers, and members of the user community. Designers and developers can provide deep understanding of the component's intended function and provide tests used to verify its functional performance before fielding. The merging of component design and development information with extensive field data, including third-party evaluation, contributes to assurance that the component is performing specified functions and that no unintended functionality is observed.

Risks to Hardware

Modern systems depend on complex microelectronics, but advances in hardware without attention to associated risks can expose critical systems, their information, and the people who rely on them. "Hardware is evolving rapidly, thus creating fundamentally new attack surfaces, many of which will never be entirely secured". (Oberg 2020) Therefore, it is imperative that risk be modeled through a dynamic risk profile and be mitigated in depth across the entire profile. Hardware assurance requires extensible mitigations and strategies that can and do evolve as threats do. Hardware assurance methods seek to quantify and improve confidence that weaknesses that can become vulnerabilities that create risks are mitigated.

Most hardware components are commercially designed, manufactured, and inserted into larger assemblies by multi-national companies with global supply chains. Understanding the provenance and participants in complex global supply chains is fundamental to assessing risks associated with the components.

Operational risks that derive from unintentional or intentional features are differentiated based on the source of the feature. Three basic operational risk areas related to goods, products, or items are: failure to meet quality standards, maliciously tainted goods, and counterfeit hardware. Counterfeits are usually offered as legitimate products, but they are not. They may be refurbished or mock items made to appear as originals, re-marked products, the result of overproduction, or substandard production parts rejected by the legitimate producer. Counterfeit risks and substandard quality offer avenues for malware insertion and potential impacts to overall system performance and availability.

Failure to follow quality standards including safety and security standards, especially in design, can result in unintentional features or flaws being inadvertently introduced. These can occur through mistakes, omissions, or lack of understanding how features might be manipulated by future users for nefarious purposes. Features introduced intentionally for specific purposes can also make the hardware susceptible to espionage or control of the hardware at some point in its life cycle.

Quantify and Improve Confidence

The quantification of hardware assurance is a key technical challenge because of the complex interplay among designer, manufacturer and supply chains, and adversarial intent, as well as the challenge of defining "security" with respect to hardware function. Quantification is necessary to identify and manage hardware risks within program budgets and timeframes. It enables a determination of the required level of hardware assurance and whether quantification is achievable throughout the hardware's life cycle.

Current methods for quantifying hardware assurance are adapted from the fields of quality and reliability engineering, which use methods like Failure Mode and Effects Analysis (FMEA). (SAE 2021) FMEA is semi-quantitative and combines probabilistic hardware failure data and input from experts. Adapting FMEA to quantify hardware assurance is hampered when it relies on assigning probabilities to human behavior that may be motivated by money, malicious intent, etc. Expert opinion often varies when quantifying and weighting factors used in generating risk matrices and scores. In response, recent efforts are attempting to develop quantitative methods that reduce subjectivity.

Game theoretic analysis (game theory) is the creation of mathematical models of conflict and cooperation between intelligent and rational decision-makers. (Myerson 1991) Models include dynamic, as opposed to static, interactions between attackers and defenders that can quantify the risks associated with potential interactions among adversaries, hardware developers, and manufacturing processes. (Eames and Johnson 2017) Creation of the models forces one to define attack scenarios explicitly and to input detailed knowledge of hardware development and manufacturing processes. Outputs of the model may include a ranking of the most likely attacks to occur based on cost-benefit constraints on the attackers and defenders. (Graf 2017) The results can empower decision-makers to make quantitative trade-off decisions about hardware assurance.

Another quantification method that results in a confidence interval for detecting counterfeit/suspect microelectronics is presented in the SAE AS6171 standard. (SAE 2016) Confidence is based on knowing the types of defects associated with counterfeits, and the effectiveness of different tests to detect those defects. Along the same lines, a standard for hardware assurance might be developed to quantify the confidence interval by testing against a catalogue of known vulnerabilities, such as those documented in the MITRE Common Vulnerabilities and Exposures (CVE) list. (MITRE 2020)

Distributed ledger technology (DLT) is an example of an emerging technology that could enable a standardized approach for quantifying hardware assurance attributes such as data integrity, immutability, and traceability. DLT can be used in conjunction with manufacturing data (such as dimensional measurement, parametric testing, process monitoring, and defect mapping) to improve tamper resistance using component provenance and traceability data. DLT also enables new scenarios of cross-organizational data fusion, opening the door to new classes of hardware integrity checks.

Manage Risks

The selection of specific components for use in subsystems and systems should be the outcome of performance-risk and cost-benefit trade-off assessments in their intended context of use. The goal of risk management and mitigation planning is to select mitigations with the best overall operational risk reduction and the lowest cost impact. The required level of hardware assurance varies with the criticality of a component's use and the system in which it is used.

During a typical development life cycle of a system – architecture, design, code, and implementation – various types of problems can pose risks to the operational functionality of the hardware components provided. These risks include weaknesses or defects that are inadvertent (unintentional), as well as counterfeits that may be either inadvertent or intentionally injected into the supply chain for financial motivations or malicious components designed to change functionality.

Managing risk in the context of hardware assurance seeks to decrease the risk of weaknesses that create attack surfaces that can be exploited, while improving confidence that an implementation resists exploitation. Ideally, risk management reduces risk and maximizes assurance to an acceptable level. Often, risks are considered in the context of likelihood of consequences and the costs and effectiveness of mitigations. However, new operationally impactful risks are recognized continuously over the hardware life cycle and supply chains of components. At the same time hardware weaknesses are often exploited through software or firmware. Therefore, to maximize assurance and minimize operationally impactful risks mitigation-in-depth across all constituent components must be considered.

This highlights the need for a dynamic risk profile.

An example of a post-manufacturing mitigation involves a new hardware risk identified during field operation. A dynamic risk profile can be used to characterize the issue and identify possible resources to address the suspect component function. This profile can also be used to track and address risks throughout its life, including obsolescence-related risk. One means of mitigating this kind of hardware life cycle risk is the use of existing programmable logic.

Just as with software patches and updates, new attack surfaces on hardware may become exposed through the mitigation being applied, and they will likely take a long time to discover. In the example above, the programmable logic is updated to provide a new configuration to protect the hardware. In this context, access to hardware reconfiguration must be limited to authorized parties to prevent an unauthorized update that introduces weaknesses on purpose or by accident. While programmable logic may have mitigated a specific attack surface or type of weakness, additional mitigations are needed to minimize risk more completely. This is mitigation-in-depth – multiple mitigations building upon one another.

Throughout the entire supply chain, critical pieces of information can be inadvertently exposed. The exposure of such information directly enables the creation and exploitation of new attack surfaces. Therefore, the supply chain infrastructure must also be assessed for weaknesses, and the development, use, and maintenance of hardware components assured. The dynamic risk profile offers a framework to balance mitigations in the context of risk and cost throughout the complete hardware and system life cycles.

System Reliability, Availability, and Maintainability

- Lead Authors:
- Paul Phister and David Olwell

-

Reliability, availability, and maintainability (RAM) are three system attributes that are of tremendous interest to systems engineers, logisticians, and users. They are often studied together. Collectively, they affect economic life-cycle costs of a system and its utility.

Overview

Reliability, maintainability, and availability (RAM) are three system attributes that are of great interest to systems engineers, logisticians, and users. Collectively, they affect both the utility and the life-cycle costs of a product or system. The origins of contemporary reliability engineering can be traced to World War II. The discipline's first concerns were electronic and mechanical components. (Ebeling 2010) However, current trends point to a dramatic rise in the number of industrial, military, and consumer products with integrated computing functions. Because of the rapidly increasing integration of computers into products and systems used by consumers, industry, governments, and the military, reliability must consider both hardware, and software.

Maintainability models present some interesting challenges. The time to repair an item is the sum of the time required for evacuation, diagnosis, assembly of resources (parts, bays, tool, and mechanics), repair, inspection, and return. Administrative delay (such as holidays) can also affect repair times. Often these sub-processes have a minimum time to complete that is not zero, resulting in the distributions used to model maintainability having a threshold parameter.

A threshold parameter is defined as the minimum probable time to repair. Estimation of maintainability can be further complicated by queuing effects, resulting in times to repair that are not independent. This dependency frequently makes analytical solution of problems involving maintainability intractable and promotes the use of simulation to support analysis.

System Description

This section sets forth basic definitions, briefly describes probability distributions, and then discusses the role of RAM engineering during system development and operation. The final subsection lists the more common reliability test methods that span development and operation.

Basic Definitions

Reliability

Reliability is defined as the probability of a product performing its intended function under stated conditions without failure for a given period of time. (ASQ 2022) A precise definition must include a detailed description of the function, the environment, the time scale, and what constitutes a failure. Each can be surprisingly difficult to define precisely.

Maintainability

The probability that a given maintenance action for an item under given usage conditions can be performed within a stated time interval when the maintenance is performed under stated conditions using stated procedures and resources. Maintainability has two categories: serviceability (the ease of conducting scheduled inspections and servicing) and repairability (the ease of restoring service after a failure). (ASQ 2022)

Availability

Defined as the probability that a repairable system or system element is operational at a given point in time under a given set of environmental conditions. Availability depends on reliability and maintainability and is discussed in detail later in this topic. (ASQ 2011)

Failure

A failure is the event(s), or inoperable state, in which any item or part of an item does not, or would not, perform as specified. (GEIA 2008) The failure mechanism is the physical, chemical, electrical, thermal, or other process that results in failure (GEIA 2008). In computerized systems, a software defect or fault can be the cause of a failure (Laprie 1992) which may have been preceded by an error which was internal to the item. The failure mode is the way or the consequence of the mechanism through which an item fails. (GEIA 2008, Laprie 1992) The severity of the failure mode is the magnitude of its impact. (Laprie 1992)

Probability Distributions used in Reliability Analysis

Reliability can be thought of as the probability of the survival of a component until time *t*. Its complement is the probability of failure before or at time *t*. If we define a random variable *T* as the time to failure, then:

where *R(t)* is the reliability and *F(t)* is the failure probability. The failure probability is the cumulative distribution function (CDF) of a mathematical probability distribution. Continuous distributions used for this purpose include exponential, Weibull, log-normal, and generalized gamma. Discrete distributions such as the Bernoulli, Binomial, and Poisson are used for calculating the expected number of failures or for single probabilities of success.

The same continuous distributions used for reliability can also be used for maintainability although the interpretation is different (i.e., probability that a failed component is restored to service prior to time *t*). However, predictions of maintainability may have to account for processes such as administrative delays, travel time, sparing, and staffing and can therefore be extremely complex.

The probability distributions used in reliability and maintainability estimation are referred to as models because they only provide estimates of the true failure and restoration of the items under evaluation. Ideally, the values of the parameters used in these models would be estimated from life testing or operating experience. However, performing such tests or collecting credible operating data once items are fielded can be costly. Therefore, approximations sometimes use data from “similar systems”, “engineering judgment”, and other methods. As a result, those estimates based on limited data may be very imprecise. Testing methods to gather such data are discussed below.

RAM Considerations during Systems Development

RAM are inherent product or system attributes that should be considered throughout the development lifecycle. Reliability standards, textbook authors, and others have proposed multiple development process models. (O’Connor 2014, Kapur 2014, Ebeling 2010, DoD 2005) The discussion in this section relies on a standard developed by a joint effort by the Electronic Industry Association and the U.S. Government and adopted by the U.S. Department of Defense (GEIA 2008) that defines 4 processes: understanding user requirements and constraints, design for reliability, production for reliability, and monitoring during operation and use (discussed in the next section).

Understanding User Requirements and Constraints

Understanding user requirements involves eliciting information about functional requirements, constraints (e.g., mass, power consumption, spatial footprint, life cycle cost), and needs that correspondent to RAM requirements. From these emerge system requirements that should include specifications for reliability, maintainability, and availability, and each should be conditioned on the projected operating environments. RAM requirements definition is as challenging but as essential to development success as the definition of general functional requirements.

Design for Reliability

System designs based on user requirements and system design alternatives can then be formulated and evaluated. Reliability engineering during this phase seeks to increase system robustness through measures such as redundancy, diversity, built-in testing, advanced diagnostics, and modularity to enable rapid physical replacement. In addition, it may be possible to reduce failure rates through measures such as use of higher strength materials, increasing the quality components, moderating extreme environmental conditions, or shortened maintenance, inspection, or overhaul intervals. Design analyses may include mechanical stress, corrosion, and radiation analyses for mechanical components, thermal analyses for mechanical and electrical components, and Electromagnetic Interference (EMI) analyses or measurements for electrical components and subsystems.

In most computer-based systems, hardware mean time between failures are hundreds of thousands of hours so that most system design measures to increase system reliability are focused on software. The most obvious way to improve software reliability is by improving its quality through more disciplined development efforts and tests. Methods for doing so are in the scope of software engineering but not in the scope of this section. However, reliability and availability can also be increased through architectural redundancy, independence, and diversity. Redundancy must be accompanied by measures to ensure data consistency, and managed failure detection and switchover. Within the software architecture, measures such as watchdog timers, flow control, data integrity checks (e.g., hashing or cyclic redundancy checks), input and output validity checking, retries, and restarts can increase reliability and failure detection coverage (Shooman 2002).

System RAM characteristics should be continuously evaluated as the design progresses. Where failure rates are not known (as is often the case for unique or custom developed components, assemblies, or software), developmental testing may be undertaken to assess the reliability of custom-developed components. Evaluations based on quantitative analyses assess the numerical reliability and availability of the system and are usually based on reliability block diagrams, fault trees, Markov models, and Petri nets. (O'Connor 2011) Markov models and Petri nets are of particular value for computer-based systems that use redundancy. Evaluations based on qualitative analyses assess vulnerability to single points of failure, failure containment, recovery, and maintainability. The primary qualitative methods are the failure mode effects and criticality analyses (FMECA). (Kececioglu 1991) The development program Discrepancy Reporting (DR) or Failure Reporting and Corrective Action System (FRACAS) should also be used to identify failure modes which may not have been anticipated by the FMECA and to identify common problems that can be corrected through an improved design or development process.

Analyses from related disciplines during design time also affect RAM. Human factor analyses are necessary to ensure that operators and maintainers can interact with the system in a manner that minimizes failures and the restoration times when they occur. There is also a strong link between RAM and cybersecurity in computer-based systems. On the one hand, defensive measures reduce the frequency of failures due to malicious events. On the other hand, devices such as firewalls, policy enforcement devices, and access/authentication serves (also known as “directory servers”) can also become single points of failure or performance bottlenecks that reduce system reliability and availability.

Production for Reliability

Many production issues associated with RAM are related to quality. The most important of these are ensuring repeatability and uniformity of production processes and complete unambiguous specifications for items from the supply chain. Other are related to design for manufacturability, storage, and transportation. (Kapur 2014; Eberlin 2010) Large software intensive information systems are affected by issues related to configuration management, integration testing, and installation testing. Testing and recording of failures in the problem reporting and corrective action systems (PRACAS) or the FRACAS capture data on failures and improvements to correct failures. Depending on organizational considerations, this may be the same or a separate system as used during the design.

Monitoring During Operation and Use

After systems are fielded, their reliability and availability are monitored to assess whether the system or product has met its RAM objectives, identify unexpected failure modes, record fixes, and assess the utilization of maintenance resources and the operating environment. The FRACAS or a maintenance management database may be used for this purpose. In order to assess RAM, it is necessary to maintain an accurate record not only of failures but also of operating time and the duration of outages. Systems that report only on repair actions and outage incidents may not be sufficient for this purpose.

An organization should have an integrated data system that allows reliability data to be considered with logistical data, such as parts, personnel, tools, bays, transportation and evacuation, queues, and costs, allowing a total awareness of the interplay of logistical and RAM issues. These issues in turn must be integrated with management and operational systems to allow the organization to reap the benefits that can occur from complete situational awareness with respect to RAM.

Reliability and Maintainability Testing

Reliability Testing can be performed at the component, subsystem, and system level throughout the product or system lifecycle. Examples of hardware related categories of reliability testing are detailed in Ebeling (2010) and O'Connor (2014).

- **Reliability Life Tests:** Reliability life tests are used to empirically assess the time to failure for non-repairable products and systems and the times between failure for repairable or restorable systems. Termination criteria for such tests can be based on a planned duration or planned number of failures. Methods to account for "censoring" of the failures or the surviving units enable a more accurate estimate of reliability. (Meeker, Escobar, Pascual 2022)
- **Accelerated Life Tests:** Accelerated life testing is performed by subjecting the items under test (usually electronic parts) to increased stress well above the expecting operating range and extrapolating results using model such as an Arrhenius relation (temperature acceleration), inverse power law (voltage), or a cumulative damage model (non-constant stress). (Meeker, Escobar, Pascual 2022)
- **Highly Accelerated Life Testing/Highly Accelerated Stress Testing (HALT/HASS):** is performed by subjecting units under test (components or subassemblies) to extreme temperature and vibration tests with the objective of identifying failure modes, margins, and design weaknesses.
- **Parts Screening:** Parts screening is not really a test but a procedure to operate components for a duration beyond the "infant mortality" period during which less durable items fail and the more durable parts that remain are then assembled into the final product or system. This is also known as "burn-in."
- **System Level Testing:** Examples of system level testing (including both hardware and software) are detailed in O'Connor (2014) and Ebeling (2010).
- **Stability Tests:** Stability tests are life tests for integrated hardware and software systems. The goal of such testing is to determine the integrated system failure rate and assess operational suitability. Test conditions must include

accurate simulation of the operating environment (including workload) and a means of identifying and recording failures.

- **Reliability Growth Tests:** Reliability growth testing is part of a reliability growth program in which items are tested throughout the development and early production cycle with the intent of assessing reliability increases due to improvements in the manufacturing process (for hardware) or software quality (for software). Also known as "Test-Analyze-And-Fix (TAAF)." (NRC 2015)
- **Failure/Recovery Tests:** Such testing assesses the fault tolerance of a system by measuring probability of switchover for redundant systems. Failures are simulated and the ability of the hardware and software to detect the condition and reconfigure the system to remain operational are tested.
- **Maintainability Tests:** Such testing assesses the system diagnostics capabilities, physical accessibility, and maintainer training by simulating hardware or software failures that require maintainer action for restoration.

Because of its potential impact on cost and schedule, reliability testing should be coordinated with the overall system engineering effort. Test planning considerations include the number of test units, duration of the tests, environmental conditions, and the means of detecting failures.

Data Issues

True RAM models for a system are generally never known. Data on a given system is assumed or collected, used to select a distribution for a model, and then used to fit the parameters of the distribution. This process differs significantly from the one usually taught in an introductory statistics course.

First, the normal distribution is seldom used as a life distribution, since it is defined for all negative times. Second, and more importantly, reliability data is different from classic experimental data. Reliability data is often censored, biased, observational, and missing information about covariates such as environmental conditions. Data from testing is often expensive, resulting in small sample sizes. These problems with reliability data require sophisticated strategies and processes to mitigate them.

One consequence of these issues is that estimates based on limited data can be and usually are very imprecise.

Discipline Management

In most large programs, RAM experts report to the system engineering organization. At project or product conception, top level goals are defined for RAM based on operational needs, lifecycle cost projections, and warranty cost estimates. These lead to RAM derived requirements and allocations that are approved and managed by the system engineering requirements management function. RAM testing is coordinated with other product or system testing through the testing organization, and test failures are evaluated by the RAM function through joint meetings such as a Failure Review Board. In some cases, the RAM function may recommend design or development process changes as a result of evaluation of test results or software discrepancy reports, and these proposals must be adjudicated by the system engineering organization, or in some cases, the acquiring customer if cost increases are involved.

Post-Production Management Systems

Once a system is fielded, its reliability and availability should be tracked. Doing so allows the producer/owner to verify that the design has met its RAM objectives, to identify unexpected failure modes, to record fixes, to assess the utilization of maintenance resources, and to assess the operating environment.

One such tracking system is generically known as a FRACAS system (Failure Reporting and Corrective Action System). Such a system captures data on failures and improvements to correct failures. This database is separate from a warranty database, which is typically run by the financial function of an organization and tracks costs only.

A FRACAS for an organization is a system, and itself should be designed following systems engineering principles. In particular, a FRACAS system supports later analyses, and those analyses impose data requirements. Unfortunately, the lack of careful consideration of the backward flow from decision to analysis to model to required data too often leads to inadequate data collection systems and missing essential information. Proper prior planning prevents this poor performance.

Of particular importance is a plan to track data on units that have not failed. Units whose precise times of failure are unknown are referred to as censored units. Inexperienced analysts frequently do not know how to analyze censored data, and they omit the censored units as a result. This can bias an analysis.

An organization should have an integrated data system that allows reliability data to be considered with logistical data, such as parts, personnel, tools, bays, transportation and evacuation, queues, and costs, allowing a total awareness of the interplay of logistical and RAM issues. These issues in turn must be integrated with management and operational systems to allow the organization to reap the benefits that can occur from complete situational awareness with respect to RAM.

Discipline Relationships

Interactions

RAM interacts with nearly all aspects of the system development effort. Specific dependencies and interactions include:

- **Systems Engineering:** RAM interacts with systems engineering as described in the previous section.
- **Product Management (Life Cycle Cost and Warranty):** RAM interacts with the product or system lifecycle cost and warranty management organizations by assisting in the calculation of expected repair rates, downtimes, and warranty costs. RAM may work with those organizations to perform tradeoff analyses to determine the most cost-efficient solution and to price service contracts.
- **Quality Assurance:** RAM may also interact with the procurement and quality assurance organizations with respect to selection and evaluation of materials, components, and subsystems.

Dependencies

- **Systems Safety:** RAM and system safety engineers have many common concerns with respect to managing the failure behavior of a system (i.e., single points of failure and failure propagation). RAM and safety engineers use similar analysis techniques, with safety being concerned about failures affecting life or unique property and RAM being concerned with those failures as well as lower severity events that disrupt operations. RAM and system safety are both concerned with failures occurring during development and test – FRACAS is the primary methodology used for RAM; hazard tracking is the methodology used for system safety.
- **Cybersecurity:** In systems or products integrating computers and software, cybersecurity and RAM engineers have common concerns relating to the availability of cyber defenses and system event monitoring. However, there are also tradeoffs with respect to access control, boundary devices, and authentication where security device failures could impact the availability of the product or system to users.

- **Software and Hardware Engineering:** Design and RAM engineers have a common goal of creating dependable products and systems. RAM interacts with the software and hardware reliability functions through design analyses such as failure modes and effects analyses, reliability predictions, thermal analyses, reliability measurement, and component specific analyses. RAM may recommend design changes as a result of these analyses that may have to be adjudicated by program management, the customer, or systems engineering if there are cost or schedule impacts.
- **Testing:** RAM interacts with the testing program during planning to assess the most efficient (or feasible) test events to perform life testing, failure/recovery testing, and stability testing as well as to coordinate requirements for reliability or stress tests. RAM also interacts with the testing organization to assess test results and analyze failures for the implications on product or system RAM.
- **Logistics:** RAM works with logistics in providing expected failure rates and downtime constraints in order for logistics engineers to determine staffing, sparing, and special maintenance equipment requirements.

Discipline Standards

Because of the importance of reliability, availability, and maintainability, as well as related attributes, there are hundreds of standards associated. Some are general but more are specific to domains such as automotive, aviation, electric power distribution, nuclear energy, rail transportation, software, etc.Standards are produced by both governmental agencies, professional associations and international standards bodies such as:

- The International Electrotechnical Commission (IEC), Geneva, Switzerland and the closely associated International Standards Organization (ISO)
- The Institute of Electrical and Electronic Engineers (IEEE), New York, NY, USA
- The Society of Automotive Engineers (SAE), Warrendale, PA, USA
- Governmental Agencies – primarily in military and space systems

The following table lists selected standards from each of these agencies. Because of differences in domains and because many standards handle the same topic in slightly different ways, selection of the appropriate standards requires consideration of previous practices (often documented as contractual requirements), domain specific considerations, certification agency requirements, end user requirements (if different from the acquisition or producing organization), and product or system characteristics.

Table 1. Selected Reliability, Availability, Maintainability standards (SEBoK Original)

Organization	Number, Title, and Year	Domain	Comment
IEC	IEC 60812, Analysis techniques for system reliability - Procedure for failure mode and effects analysis (FMEA), 2006	General	
IEC	IEC 61703 Ed 2.0, Mathematical expressions for reliability, availability, maintainability and maintenance support terms [1], 2016	General	
IEC	IEC 62308, Equipment reliability - Reliability assessment methods, 2006	General	
IEC	IEC 62347, Guidance on system dependability specifications, 2006	General	
IEC	IEC 62278, Railway applications – Specification and demonstration of reliability, availability, maintainability and safety (RAMS), 2002	Railways	

IEEE	IEEE Std 352-2016, IEEE Guide for General Principles of Reliability Analysis of Nuclear Power Generating Station Safety Systems and Other Nuclear Facilities [2], 2016	Nuclear Energy	
IEEE	IEEE Std 1044-2009, IEEE Standard Classification for Software Anomalies, 2009	Software	
IEEE	IEEE Std 1633-2008, IEEE Recommended Practice on Software Reliability [3], 2016	Software	
SAE	ARP 4754A, Guidelines for the Development of Civil Aircraft and Systems, 2010	Aviation	
SAE	ARP 5890B, Guidelines for Preparing Reliability AssessmentPlans for Electronic Engine Controls [4], 2018	Aviation	
SAE	J2940_202002, Use of Model Verification and Validation in Product Reliability and Confidence Assessments [5], 2020	General	
SAE	SAE-GEIA-STD-0009A, Reliability Program Standard for SystemsDesign, Development, and Manufacturing [6], 2020	General	Used by the U.S. Dept. of Defense as the primary reliability standard (replaces MIL-STD-785B)
SAE	JA 1002_201205, Software Reliability Program Standard [7], 2012	Software	
U.S. Government	NASA-STD-8729.1A, Planning, Developing and Managing an Effective Reliability And Maintainability (R&M) Program [8], 2017	Space Systems	
U.S. Government	MIL HDBK 470A, Designing and Developing Maintainable Products and Systems [9], 1997	Defense Systems	
U.S. Government	MIL HDBK 217F (Notice 2), Reliability Prediction of Electronic Equipment [10], 1995	Defense Systems	Although formally titled a “Handbook” and more than 2 decades old, the values and methods constitute a de facto standard for some U.S. military acquisitions
U.S. Government	MIL-STD-1629A (Notice 3), Procedures for Performing a Failure Mode Effects and Criticality Analysis -Revision A [11], 1998		The parent of FMEA standards produced by the IEEE, SAE, ISO, and many other agencies. Still valid and in use after 4 decades.

Personnel Considerations

Becoming a reliability engineer requires education in probability and statistics as well as the specific engineering domain of the product or system under development or in operation. A number of universities throughout the world have departments of reliability engineering (which also address maintainability and availability) and more have research groups and courses in reliability and safety – often within the context of another discipline such as computer science, systems engineering, civil engineering, mechanical engineering, or bioengineering. Because most academic engineering programs do not have a full reliability department, most engineers working in reliability have been educated in other disciplines and acquire the additional skills through additional coursework or by working with other qualified engineers. A certification in reliability engineering [12] is available from the American Society for Quality (ASQ 2016). However, only a minority of engineers working in the discipline have this certification.

Metrics

The three basic metrics of RAM are (not surprisingly) Reliability, Maintainability, and Availability. Reliability can be characterized in terms of the parameters, mean, or any percentile of a reliability distribution. However, in most cases, the exponential distribution is used, and a single value, the mean time to failure (MTTF) for non-restorable systems, or mean time between failures (MTBF for restorable systems are used). The metric is defined as:

where is the total operating time and is the number of failures.

Maintainability is often characterized in terms of the exponential distribution and the mean time to repair and be similarly calculated, i.e.,

Where is the total down time and is the number of outages.

As was noted above, accounting for downtime requires definitions and specificity. Down time might be counted only for corrective maintenance actions, or it may include both corrective and preventive maintenance actions. Where the lognormal rather than the exponential distribution is used, a mean down time can still be calculated, but both the log of the downtimes and the variance must be known in order to fully characterize maintainability. Availability can be calculated from the total operating time and the downtime, or in the alternative, as a function of MTBF and MTTR (Mean Time To Repair.)

As was the case with maintainability, availability may be qualified as to whether it includes only unplanned failures and repairs (inherent availability) or downtime due to all causes including administrative delays, staffing outages, or spares inventory deficiencies (operational availability).

Probabilistic metrics describe system performance for RAM. Quantiles, means, and modes of the distributions used to model RAM are also useful.

Availability has some additional definitions, characterizing what downtime is counted against a system. For **inherent availability**, only downtime associated with corrective maintenance counts against the system. For **achieved availability**, downtime associated with both corrective and preventive maintenance counts against a system. Finally, **operational availability** counts all sources of downtime, including logistical and administrative, against a system.

Availability can also be calculated instantaneously, averaged over an interval, or reported as an asymptotic value. **Asymptotic availability** can be calculated easily, but care must be taken to analyze whether or not a system settles down or settles up to the asymptotic value, as well as how long it takes until the system approaches that asymptotic value.

Reliability importance measures the effect on the system reliability of a small improvement in a component's reliability. It is defined as the partial derivative of the system reliability with respect to the reliability of a component.

Criticality is the product of a component's reliability, the consequences of a component failure, and the frequency with which a component failure results in a system failure. Criticality is a guide to prioritizing reliability improvement efforts.

Many of these metrics cannot be calculated directly because the integrals involved are intractable. They are usually estimated using simulation.

Models

There are a wide range of models that estimate and predict reliability (Meeker, Escobar, Pascual 2022). Simple models, such as exponential distribution, can be useful for "back of the envelope" calculations.

System models are used to (1) combine probabilities or their surrogates, failure rates and restoration times, at the component level to find a system level probability or (2) to evaluate a system for maintainability, single points of failure, and failure propagation. The three most common are reliability block diagrams, fault trees, and failure modes and effects analyses.

There are more sophisticated probability models used for life data analysis. These are best characterized by their failure rate behavior, which is defined as the probability that a unit fails in the next small interval of time, given it has lived until the beginning of the interval, and divided by the length of the interval.

Models can be considered for a fixed environmental condition. They can also be extended to include the effect of environmental conditions on system life. Such extended models can in turn be used for accelerated life testing (ALT), where a system is deliberately and carefully overstressed to induce failures more quickly. The data is then extrapolated to usual use conditions. This is often the only way to obtain estimates of the life of highly reliable products in a reasonable amount of time. (Nelson 1990)

Also useful are **degradation models**, where some characteristic of the system is associated with the propensity of the unit to fail (Nelson 1990). As that characteristic degrades, we can estimate times of failure before they occur.

The initial developmental units of a system often do not meet their RAM specifications. **Reliability growth models** allow estimation of resources (particularly testing time) necessary before a system will mature to meet those goals. (Meeker, Escobar, and Pascual 2022, NRC 2015)

Maintainability models describe the time necessary to return a failed repairable system to service. They are usually the sum of a set of models describing different aspects of the maintenance process (e.g., diagnosis, repair, inspection, reporting, and evacuation). These models often have threshold parameters, which are minimum times until an event can occur.

Logistical support models attempt to describe flows through a logistics system and quantify the interaction between maintenance activities and the resources available to support those activities. Queue delays, in particular, are a major source of down time for a repairable system. A logistical support model allows one to explore the trade space between resources and availability.

All these models are abstractions of reality, and so at best approximations to reality. To the extent they provide useful insights, they are still very valuable. The more complicated the model, the more data necessary to estimate it precisely. The greater the extrapolation required for a prediction, the greater the imprecision.

Extrapolation is often unavoidable, because high reliability equipment typically can have long life and the amount of time required to observe failures may exceed test times. This requires strong assumptions be made about future life (such as the absence of masked failure modes) and that these assumptions increase uncertainty about predictions. The uncertainty introduced by strong model assumptions is often not quantified and presents an unavoidable risk to the system engineer.

There are many ways to characterize the reliability of a system, including fault trees, reliability block diagrams, and failure mode effects analysis.

A **Fault Tree** (Kececioglu 1991) is a graphical representation of the failure modes of a system. It is constructed using logical gates, with AND, OR, NOT, and K of N gates predominating. Fault trees can be complete or partial; a partial fault tree focuses on a failure mode or modes of interest. They allow "drill down" to see the dependencies of systems on nested systems and system elements. Fault trees were pioneered by Bell Labs in the 1960s.

A Failure Mode Effects Analysis is a table that lists the possible failure modes for a system, their likelihood, and the effects of the failure. A Failure Modes Effects Criticality Analysis scores the effects by the magnitude of the product

of the consequence and likelihood, allowing ranking of the severity of failure modes. (Kececioglu 1991)

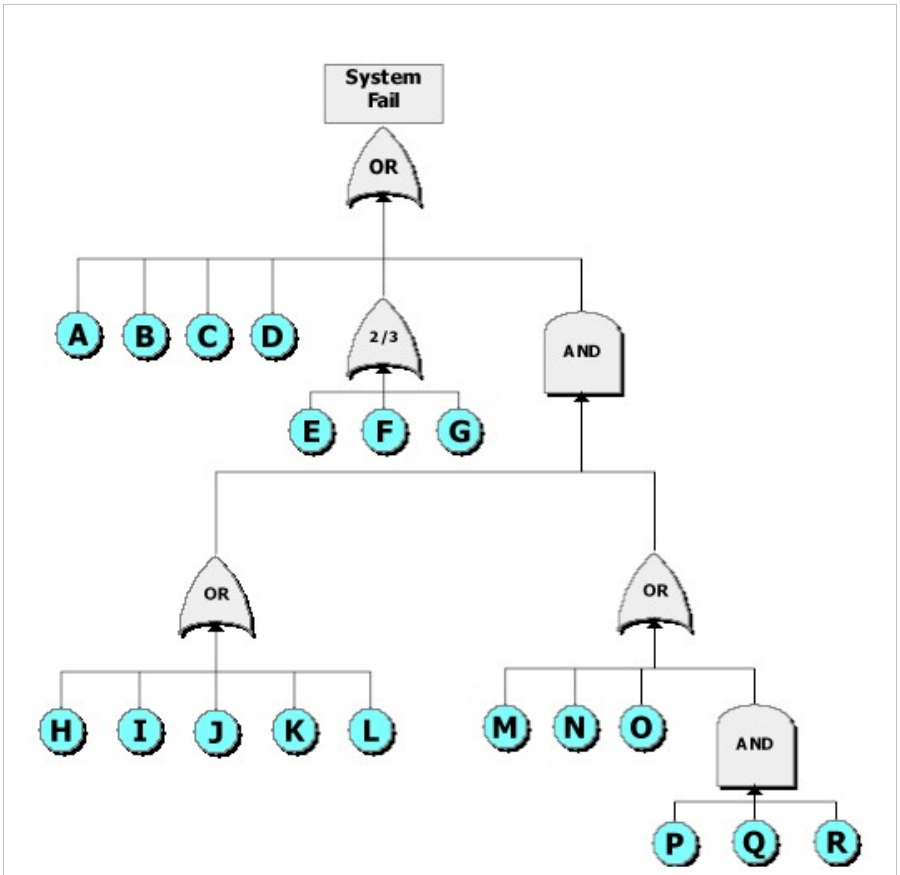

Figure 1. Fault Tree. (SEBoK Original)

A **Reliability Block Diagram** (RBD) (DOD, 1998) is a graphical representation of the reliability dependence of a system on its components. It is a directed, acyclic graph. Each path through the graph represents a subset of system components. As long as the components in that path are operational, the system is operational. Component lives are usually assumed to be independent in an RBD. Simple topologies include a series system, a parallel system, a *k* of *n* system, and combinations of these.

RBDs are often nested, with one RBD serving as a component in a higher-level model. These hierarchical models allow the analyst to have the appropriate resolution of detail while still permitting abstraction.

RBDs depict paths that lead to success, while fault trees depict paths that lead to failure.

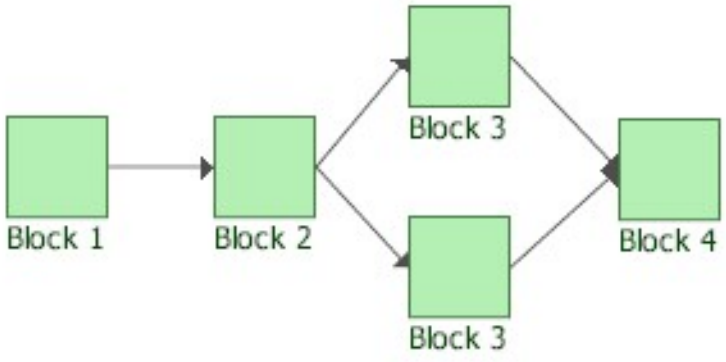

Figure 2. Simple Reliability Block Diagram. (SEBoK Original)

A **Failure Mode Effects Analysis** is a table that lists the possible failure modes for a system, their likelihood, and the effects of the failure. A **Failure Modes Effects Criticality Analysis** scores the effects by the magnitude of the product of the consequence and likelihood, allowing ranking of the severity of failure modes. (Kececioglu 1991)

System models require even more data to fit them well. "Garbage in, garbage out" (GIGO) particularly applies in the case of system models.

Tools

The specialized analyses required for RAM drive the need for specialized software. While general purpose statistical languages or spreadsheets can, with sufficient effort, be used for reliability analysis, almost every serious practitioner uses specialized software.

Minitab (versions 13 and later) includes functions for life data analysis. Win Smith is a specialized package that fits reliability models to life data and can be extended for reliability growth analysis and other analyses. Relex has an extensive historical database of component reliability data and is useful for estimating system reliability in the design phase.

There is also a suite of products from ReliaSoft (2007) that is useful in specialized analyses. Weibull++ fits life models to life data. ALTA fits accelerated life models to accelerated life test data. BlockSim models system reliability, given component data.

Discipline Specific Tool Families

Reliasoft [13] and PTC Windchill Product Risk and Reliability [14] produce a comprehensive family of tools for component reliability prediction, system reliability predictions (both reliability block diagrams and fault trees), reliability growth analysis, failure modes and effects analyses, FRACAS databases, and other specialized analyses. In addition to these comprehensive tool families, there are more narrowly scoped tools. Minitab (versions 13 and later) includes functions for life data analysis.

General Purpose Statistical Analysis Software with Reliability Support

Some general-purpose statistical analysis software includes functions for reliability data analysis. Minitab [15] has a module for reliability and survival analysis. SuperSmith [16] is a more specialized package that fits reliability models to life data and can be extended for reliability growth analysis and other analyses.

R [17] is a widely used open source and well-supported general purpose statistical language with specialized packages that can be used for fitting reliability models, Bayesian analysis, and Markov modeling.

Special Purpose Analysis Tools

Fault tree generation and analysis tools include CAFTA [18] from the Electric Power Research Institute and OpenFTA [19], an open source software tool originally developed by Auvation Software.

PRISM [20] is an open source probabilistic model checker that can be used for Markov modeling (both continuous and discrete time) as well as for more elaborate analyses of system (more specifically, "timed automata") behaviors such as communication protocols with uncertainty.

System Resilience

- Lead Author:
- John Brtis
- Contributing Authors:
- Ken Cureton, Scott Jackson, and Ivan Taylor

-

Resilience is a relatively new term in the SE realm, appearing around 2006 and becoming popularized in 2010. The application of “resilience” to engineered systems has led to a proliferation of alternative definitions. While the details of definitions will continue to be debated, the information here should provide a working understanding of the meaning and implementation of resilience, sufficient for an engineer to address it effectively.

Overview

Definition

According to the Oxford English Dictionary, resilience is “the act of rebounding or springing back” (OED 1973). This definition fits materials that return to their original shape after deformation. For human-made or **engineered systems**, the definition of **resilience** can be extended to "maintaining **capability** in the face of an **adversity**."

Some practitioners limit the definition of resilience to only the system reactions following an encounter with an adversity in what is known as the "reactive perspective" regarding system resilience. The "proactive perspective" defines system resilience to include actions that occur *before* encountering adversity as well. The INCOSE Resilient Systems Working Group (RSWG) asserts that resilience should address both the reactive and proactive perspectives.

The RSWG defines resilience as "the ability to provide required capability when facing adversity", as depicted in **Figure 1**.

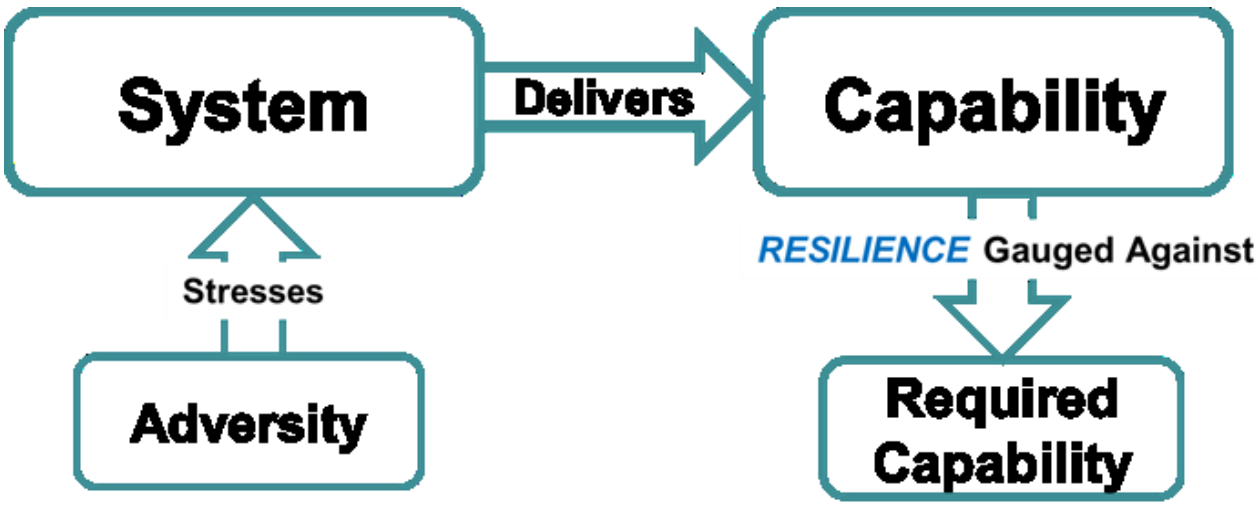

Figure 1. General Depiction of Resilience (Brtis & McEveley 2016, Used with Permission)

Scope of the Means

In applying this definition, one needs to consider the range of means by which resilience is achieved. The high-level means, and fundamental objectives of resilience include avoiding, withstanding, and recovering from adversity (Brtis and McEvilley 2019). "Withstanding" and "recovering" from adversity are classic aspects of resilience. For the purpose of engineered systems, "avoiding" adversity is also an important means of achieving resilience (Jackson and Ferris 2016). Finer granularity low-level means of achieving resilience are discussed in the taxonomy portion of this article.

Scope of the Adversity

An adversity is any condition that could degrade the delivered capability of a system. When discussing system resilience, the full spectrum of sources and types of adversity should be considered. For example, adversity may come from within the system or from the system's environment, and can be expected or unexpected. Adversity may also come from opponents, friendlies or neutral parties, and if from human sources, can be malicious or accidental (Brtis & McEvilley 2020).

"Stress" and "strain" are two useful concepts for understanding adversities. Adversities may affect the system through a causal chain of adversities. The proximate adversities that affect the system directly (rather than indirectly) are called "stresses" on the system. The effects on the system are referred to as "strains" on the system.

It is important to recognize that risks that can impact a system in the future can cause a detrimental **strain** on the system in the present. Systems should be designed to be resilient to future risks, just as they are to current issues.

Taxonomy for Achieving Resilience

A taxonomy describing the fundamental objectives of resilience and the means for achieving those objectives is valuable to the engineer developing a resilient design. It is important to distinguish "fundamental objectives" from "means objectives" and their impact on trades and engineering decision-making (Clemen & Reilly 2001; Keeney 1992).

A three-layer objectives-based taxonomy that implements this distinction is provided below. The first level addresses the fundamental objectives of resilience, the second level addresses the means objectives of resilience, and the third level addresses architecture, design, and operational techniques for achieving resilience. The three layers are related by many-to-many relationships. The terms and their descriptions are, in many cases, tailored to best address the context of resilience. (Most of the taxonomy content came from Brtis (2016), Jackson and Ferris (2013), Winstead (2020), with other content developed over time by the RSWG.)

Taxonomy Layer 1: The Fundamental Objectives of Resilience

Fundamental objectives are the first level decomposition of resilience objectives. They establish the scope of resilience. They identify the values pursued by resilience. They represent an extension of the definition of resilience. They are ends in themselves rather than just means to other ends. They should be relatively immutable. Being resilient means achieving three fundamental objectives:

- **Avoid adversity:** eliminate or reduce exposure to **stress**
- **Withstand adversity:** resist capability degradation when stressed
- **Recover from adversity:** replenish lost capability after degradation

These *fundamental* objectives can be achieved by pursuing *means* objectives. Means objectives are not ends in themselves. Their value resides in helping to achieve the three fundamental objectives.

Taxonomy Layer 2: Means Objectives

Means objectives are not ends in themselves but enable achieving the fundamental objectives in Layer 1. This level tends to reflect the stakeholder perspective. The means objectives are high-level functional requirements that should be considered during the stakeholder needs and requirements definition process. The definitions and descriptions are specific to how each concept is applied for resilience.

- **adapt:** be or become able to deliver required capability in changing situations. This allows systems to function in changing conditions. Adaptability address known-unknowns, and potentially, unknown-unknowns. It may be real-time, near-term, or long-term. The system may adapt itself or be adapted by external actors. The driving situation changes may be in the adversities, environment, system state, required capability, mission, business, stakeholders, stakeholder needs and requirements, system requirements, system architecture, or design. Adaptability is related to **flexibility**, **agility**, and evolution, and serves as a complement to the “preserve integrity” objective. (See the entry for "evolve" below as well.) Examples of adaptability include adding a crumple zone to an automobile, streaming services shifting to different modalities when faced by unexpectedly high loads or anomalies, self-healing systems, etc.
- **anticipate:** (1) consider and understand potential adversities, their consequences, and appropriate responses -- before the system is stressed; and/or (2) develop and maintain courses of design and operation that address predicted adversity. Anticipation facilitates the mitigation of risks before they manifest. The "anticipate" objective is similar to the “prepare” objective. Examples include use of prognostic data, predictive maintenance, hurricane early warning systems, and emergency response planning.
- **constrain:** withstand stress by limiting damage propagation within the system. Examples include fault containment, circuit breakers, fire walls, multiple independent levels of security, vaccines, amputation, etc.
- **continue:** withstand and recover from stress to deliver required capability, while and after being stressed. Examples include fail-safe, backup capability, redundant capability, fault tolerance, rapid recovery, etc.
- **degrade gracefully:** withstand stress by transitioning to desirable system state(s) after degradation. This allows partial useful functionality instead of complete system failure. Examples include automobile crumple zone absorption of kinetic energy, deorbiting a satellite, safety system engagement, and failing over to backup systems.
- **disaggregate:** disperse functions, systems, or system elements. This eliminates a single point of failure and eliminates a single target for opponents. Examples include processor load distribution, mechanical/electrical/thermal load distribution, networks, the nuclear triad, etc.
- **evade:** avoid adversity through design or action. Examples include stealth and maneuver.
- **evolve:** adapt over time. Examples include: B-52 transition to multiple roles, upgrading software-defined radio capabilities, and adoption of fuel injection to address fuel economy needs.
- **fortify:** strengthen the system to withstand stress. Examples include shielding, strengthening weakest “links,” and protective aircraft cockpits.
- **manage complexity:** reduce adversity or its effects by eliminating unnecessary complexity and the resulting unintended consequences. Unintended consequences can be or can create an adversity, or they may cause an inappropriate response to adversity. Examples include the principle of “Keep it Simple Stupid” and suppressing undesirable emergent behavior.
- **minimize adversity:** avoid adversity by reducing the amount or effectiveness of adversities. Examples include battlefield preparation, and fighting an infection (biological).
- **minimize faults:** avoid adversity by reducing the likelihood and severity of adversities arising within the system, such as by using system elements with a long mean time to failure.
- **monitor:** observe and evaluate changes or developments that could lead to degradation. This allows projection and anticipation of future status, to allow early detection and early response. An example would be smart grid real-time power monitoring.
- **preserve integrity:** withstand adversity by remaining complete and unaltered. This is a compliment to “adapt/evolve.” Examples include blockchain, which provides tamper-proof data logging and cryptographic digital

signatures.

- **prevent:** avoid degradation by precluding the realization of strain on the system. Examples include backup power to serve critical system capability, anti-corrosion coatings, etc.
- **reduce vulnerability**: better withstand adversity by identifying system vulnerabilities and modifying the system to reduce the degradation caused by adversity. Examples include performing and acting on Failure Modes and Effects Analysis (FMEA), reducing the attack surface, hardening vulnerable components, and flood-resistant urban infrastructures.
- **repair:** recover by fixing damage.
- **replace:** recover by substituting a capable element for a degraded one.
- **tolerate:** withstand degraded capability. Examples include excess margin, RAID storage, an aircraft hydraulic redundancy.
- **understand:** develop and maintain useful representations of required system capabilities, how those capabilities are generated, the system environment, and the potential for degradation due to adversity. Examples include digital twins, and battlefield simulations.

Taxonomy Layer 3: Architecture, Design, and Operational Techniques to Achieve Resilience Objectives

Architecture, design, and operational techniques that may achieve resilience objectives are listed below. This level tends to represent the system viewpoint, and should be considered during the system requirements, system architecture, design definition, and operation processes. The definitions and descriptions are specific to how each concept is applied for resilience.

- **absorption:** withstanding adversity by assimilating stress without unacceptable degradation of the system capability. Examples include dissipating kinetic energy with automobile crumple zones.
- **adaptability**: see “adapt” in layer 2 above. Adaptability has commonality with flexibility, agility, improvising, overcoming.
- **anomaly detection:** discovering salient abnormalities in the system or its environment to enable effective response.
- **backward recovery:** recovery to a previous stable state of a system.
- **boundary enforcement:** implementing the process, temporal, and spatial limits to protect the system.
- **buffering:** reducing the effect of degradation through excess capacity.
- **coordinated defense:** having multiple, synergistic mechanisms to protect required capability, such as via the defense-in-depth strategy.
- **deception:** confusing and thus impeding an adversary.
- **defense-in-depth:** minimizing loss by employing multiple coordinated mechanisms, each of which can at least partially achieve resilience.
- **detection avoidance:** reducing an adversary's awareness of the system. Examples include stealth.
- **distributed privilege:** requiring multiple authorized entities to act in a coordinated manner before a system function can proceed. Examples include authorization for use of nuclear weapons.
- **distribution:** spreading the system’s ability to perform – physically or virtually.
- **diversification:** use of heterogeneous design techniques to minimize common vulnerabilities and common mode failures. Examples include heterogeneous technologies, data sources, processing locations, equipment locations, supply chains, communications paths.
- **domain separation:** physically or logically isolating items with different protection needs.
- **drift correction:** monitoring the system’s movement toward the boundaries of proper operation and taking corrective action.
- **dynamic positioning:** relocation of system functionality or components to confound opponent understanding of the system.

- **effect tolerance:** providing required capability despite damage to the system.
- **error recovery:** detection, control, and correction of internal errors.
- **fail soft:** prioritizing and gradually terminating affected functions when failure is imminent.
- **fault tolerance:** providing required capability in spite of faults.
- **forward recovery:** recovery by restoring the system to a new, not previously occupied state in which it can perform required functions.
- **human participation:** including people as part of the system. A human in the loop brings a unique capability for agile and adaptable thinking and action.
- **least functionality:** system elements accomplish their required functions, but no more.
- **least persistence:** system elements are available, accessible, and fulfill their design intent only while needed.
- **least privilege:** system elements are allocated authorizations necessary to accomplish their specified functions, but not more.
- **least sharing:** system resources are accessible by multiple system elements only when necessary, and to as few system elements as possible.
- **loose coupling**: minimizing the interdependency of elements. This can reduce the potential for propagation of damage.
- **loss margins:** excess capability, so partial capability degradation is acceptable.
- **maintainability:** ability to be retained or restored to perform as required.
- **mediated access:** controlling the ability to access and use system elements.
- **modeling and analytic monitoring:** developing a representation of the system; and gathering, and analyzing data based on that understanding, to identify vulnerabilities, find indications of potential or actual adverse conditions, identify potential or actual system degradation and evaluate the efficacy of system countermeasures.
- **modularity:** composing a system of discrete elements so that a change to one component has a minimal impact on other elements.
- **neutral state:** providing a condition of the system where stakeholders (especially operators) can safely take no action while awaiting determination of the most appropriate action.
- **protection:** mitigation of stress to the system.
- **protective defaults:** providing default configurations of the system that provide protection.
- **protective failure:** ensuring that failure of a system element does not result in an unacceptable loss of capability.
- **protective recovery:** ensuring that recovery of a system element does not result in unacceptable loss of capability.
- **realignment:** reconfigure the system architecture to improve the system's resilience.
- **rearchitect/redesign:** Modify the system elements or system structure for improved resilience.
- **redeploy:** reorganize resources to provide required capabilities and address adversity or degradation. Examples include rapid launch to replace satellites lost from a constellation, emergency vehicle repositioning during disasters.
- **redundancy:** having more than one means for performing the required function. This can mitigate single point failures. Examples include: multiple pumps in parallel.
- **redundancy (functional):** achieving redundancy by heterogeneous means. This can mitigate common mode failures and common case failures. This is also called, "homogeneous redundancy."
- **redundancy (physical):** achieving redundancy by more than one identical element.
- **repairability:** the ease with which a system can be restored to an acceptable condition.
- **replacement:** changing system elements to regain capability.
- **safe state:** providing the ability to transition to a state that does not lead to unacceptable loss of capability.
- **segmentation:** separation (logically or physically) of elements to limit the spread of damage.
- **shielding:** interposition of items (physical or virtual) that inhibit the adversity's ability to stress the system.
- **substantiated integrity**: ability to ensure and prove that system elements have not been corrupted.

- **substitution:** using new system elements to provide or restore capability.
- **unpredictability:** making changes randomly that confound an opponent's understanding of the system.
- **virtualization**: creating a simulated, rather than actual, version of something. This facilitates stealth, dynamic positioning, and unpredictability. Examples include virtual computer hardware platforms, storage devices, and network resources.

The means objectives and architectural and design techniques will evolve as the resilience engineering discipline matures.

The Resilience Process

Resilience should be considered throughout a system's life cycle, but most especially in early life cycle activities that lead to resilience requirements. Once resilience requirements are established, they can and should be managed along with all the other requirements in the trade space. Specific considerations for inclusion in early life cycle activities can include the following items listed below (Brtis and McEvilley 2019).

- **Business or Mission Analysis Process**
  - Defining the problem space should include identification of adversities and expectations for performance under those adversities.
  - ConOps, OpsCon, and solution classes should consider the ability to avoid, withstand, and recover from adversities.
  - Evaluation of alternative solution classes must consider ability to deliver required capabilities under adversity.
- **Stakeholder Needs and Requirements Definition Process**
  - The stakeholder set should include people who understand potential adversities and stakeholder resilience needs.
  - When identifying stakeholder needs, identify expectations for capability under adverse conditions and degraded/alternate, but useful, modes of operation.
  - Operational concept scenarios should include resilience scenarios.
  - Transforming stakeholder needs into stakeholder requirements includes stakeholder resilience requirements.
  - Analysis of stakeholder requirements includes resilience scenarios in the adverse operational environment.
- **System Requirements Definition Process**
  - Resilience should be considered in the identification of requirements.
  - Achieving resilience and other adversity-driven considerations should be addressed in concert.
- **Architecture Definition Process**
  - Selected viewpoints should support the representation of resilience.
  - Resilience requirements can significantly limit and guide the range of acceptable architectures. Resilience requirements must be mature when used for architecture selection.
  - Individuals developing candidate architectures should be familiar with architectural techniques for achieving resilience.
  - Achieving resilience and other adversity-driven considerations should be addressed in concert.
- **Design Definition Process**
  - Individuals developing candidate designs should be familiar with design techniques for achieving resilience.
  - Achieving resilience and the other adversity-driven considerations should be addressed in concert.
- **Risk Management Process**
  - Risk management should be planned to handle risks, issues, and opportunities identified by resilience activities.

Resilience Metrics

Commonly used resilience metrics include the following (Uday and Marais 2015):

- Time duration of failure
- Time duration of recovery
- Ratio of performance recovery to performance loss
- The speed of recovery
- Performance before and after the disruption and recovery actions
- System importance measures

However, resilience principles that are implied or substantiated by recommendations by domain experts are often missing in practice (Jackson and Ferris 2013). This has led to the development of a new metric for evaluating various systems in domains (aviation, fire protection, rail, and power distribution) to address resilience principles that are often omitted (Jackson 2016).

Numerous candidate resilience metrics have also been identified, including the following (Brtis 2016):

- Maximum outage period
- Maximum brownout period
- Maximum outage depth
- Expected value of capability: the probability-weighted average of capability delivered
- Threat resiliency; i.e. the time integrated ratio of the capability provided divided by the minimum needed capability
- Expected availability of required capability; i.e. the likelihood that for a given adverse environment the required capability level will be available
- Resilience levels; i.e. the ability to provide required capability in a hierarchy of increasingly difficult adversity
- Cost to the opponent
- Cost-benefit to the opponent
- Resource resiliency; i.e. the degradation of capability that occurs as successive contributing assets are lost

Multiple metrics may be required depending on the situation. If one has to select a single most effective metric for reflecting the meaning of resilience, consider "the expected availability of the required capability", where the probability-weighted availability is summed across the scenarios under consideration (Brtis 2016).

Resilience Requirements

Resilience requirements often take the form of resilience scenarios, which can often be found in ConOps or OpsCons.

The following information is often part of a resilience requirement (Brtis & McEvilley 2019):

- operational concept name
- system or system portion of interest
- capability(s) of interest their metric(s) and units
- target value(s); i.e., the required amount of capabilities
- system modes of operation during the scenario, e.g., operational, training, exercise, maintenance, and update
- system states expected during the scenario
- adversity(s) being considered, their source, and type
- potential stresses on the system, their metrics, units, and values (Adversities may affect the system directly or indirectly. Stresses are adversities that directly affect the system.)
- resilience related scenario constraints, e.g., cost, schedule, policies, and regulations
- timeframe and sub-timeframes of interest
- resilience metric, units, determination methods, and resilience metric target

- impact on other systems if the system of interest fails its resilience goals

Importantly, many of these parameters may vary over the timeframe of the scenario (see **Figure 2**). A single resilience scenario may involve multiple adversities, which may be involved at multiple times during the scenario.

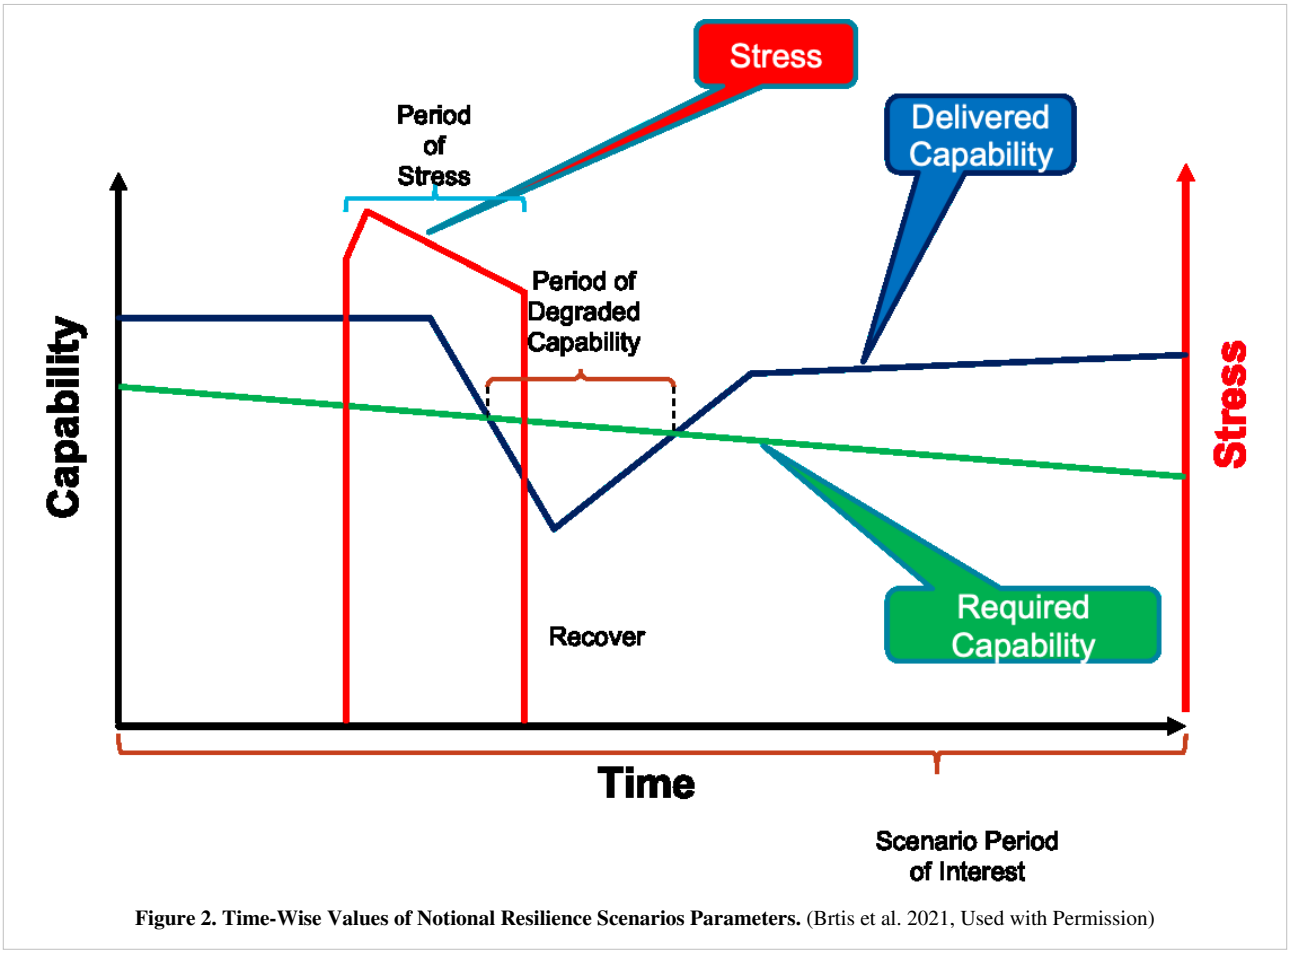

Figure 2. Time-Wise Values of Notional Resilience Scenarios Parameters. (Brtis et al. 2021, Used with Permission)

Resilience requirements are compound requirements. They can be classified into three forms: (1) natural language, (2) entity-relationship diagram (data structure), and (3) an extension to SysML. All contain the same information, but are in forms that meet the needs of different audiences (Brtis et al. 2021). An example of a natural language pattern for representing a resilience requirement is:

> The <system, mode(t), state(t)> encountering <adversity(t), source, type>, which imposes <stress(t), metric, units, value(t)> thus affecting delivery of <capability(t), metric, units> during <scenario timeframe, start time, end time, units> and under <scenario constraints>, shall achieve <resilience target(t) (include excluded effects)> for <resilience metric, units, determination method>

Affordable Resilience

"Affordable resilience" means achieving an effective balance between cost and system resilience over the system life cycle. Life cycle considerations for affordable resilience should address not only risks and issues associated with known and unknown adversities over time, but also opportunities for gain in known and unknown future environments. This may require balancing the time value of funding vs. the time value of resilience in order to achieve affordable resilience as shown in **Figure 3**.

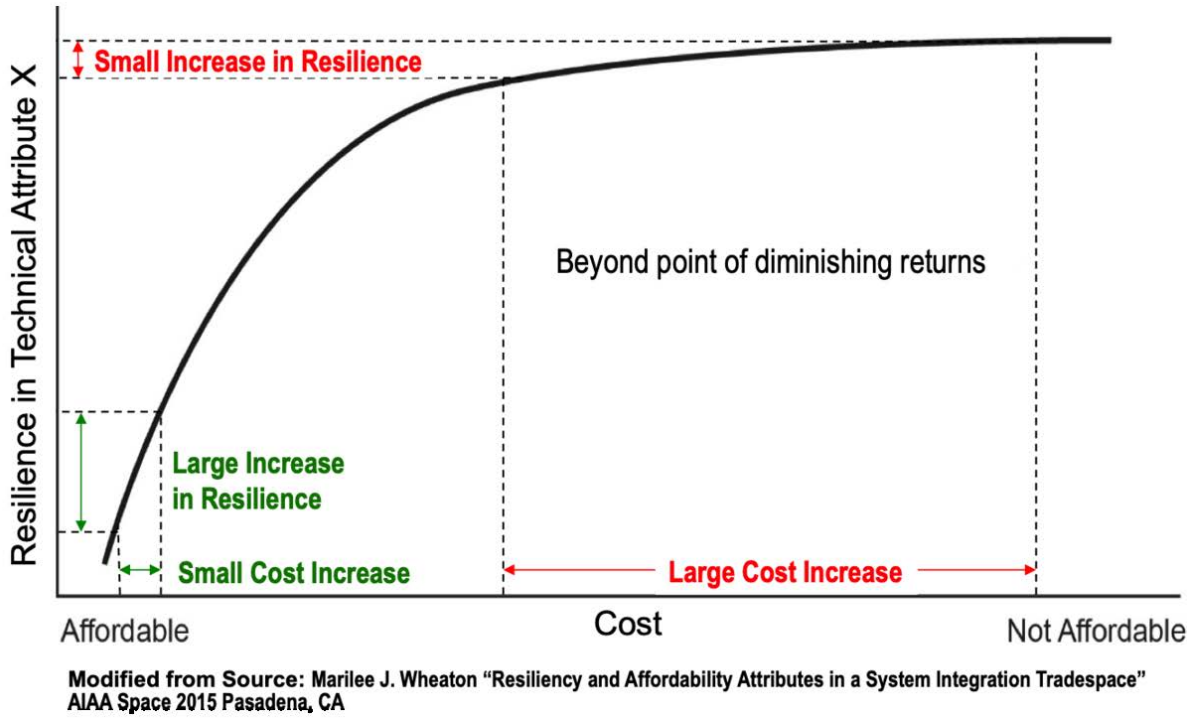

Figure 3. Resilience versus Cost. (Wheaton 2015, Used with Permission)

Once affordable levels of resilience are determined for each key technical attribute, the affordable levels across those attributes can be prioritized via standard techniques, such as Multi-attribute Utility Theory (MAUT) (Keeney and Raiffa 1993) or Analytical Hierarchy Process (AHP) (Saaty 2009).

The priority of affordable resilience attributes for systems is typically domain-dependent. For example:

- Electronic funds transfer systems may emphasize transaction security, meeting regulatory requirements, and liability risks
- Unmanned space exploration systems may emphasize survivability to withstand previously-unknown environments, usually with specified (and often limited) near-term funding constraints
- Electrical power grids may emphasize safety, reliability, and meeting regulatory requirements together with adaptability to changing power generation and storage technologies, shifts in power distribution and usage, etc.
- Medical capacity for disasters may emphasize rapid adaptability, with affordable planning, preparation, response, and recovery levels to meet public health demands. This emphasis must balance potential liability with medical practices, such as triage and "first do no harm".

Discipline Relationships

Resilience has commonality and synergy with many other quality characteristics. Examples include availability, environmental impact, survivability, maintainability, reliability, operational risk management, safety, security, and quality. This group of quality characteristics forms what is called loss-driven systems engineering (LDSE), because they focus on potential losses involved in developing and using systems (INCOSE 2020). These areas frequently share the assets considered, losses considered, adversities considered, requirements, and architectural, design and operational techniques. It is imperative that these areas work closely with one another and share information and decision-making.

The concept of pursuing loss-driven systems engineering, its benefits, and the means by which it can be pursued are addressed in the SEBoK Part 6 article focused on LDSE and the 2020 INCOSE INSIGHT issue on LDSE.

Discipline Standards

Two standards stand out for insight on resilience:

- ASISI (2009) is a standard pertaining to the resilience of organizational systems.
- NIST 800-160 (Ross, R. et al. 2018) considers the resilience of physical systems.

Personnel Considerations

People are important components of systems for which resilience is desired. This aspect is reflected in the human-in-the-loop technique. (Jackson and Ferris 2013). A human in the loop brings a unique capability for agile and adaptable thinking and action. Decisions made by people are at the discretion of the decision-makers in real time, as exemplified by the Apollo 11 mission (Eyles 2009) and similar examples.

Organizational Resilience

Because organizational systems and cyber-physical systems differ significantly, it is not surprising that resilience is addressed differently in each. Organizations, as systems, typically view resilience in terms of managing continuity of operations when facing adverse events and apply a host of processes focused on ensuring that the organization's core functions can withstand disruptions, interruptions, and adversities. ISO 22301 addresses requirements for security and resilience in business continuity management systems. It is an international standard that provides requirements appropriate to the amount and type of impact the organization may or may not accept following a disruption.

Resilient organizations require resilient employees. Resilient organizations and resilient people generally have the following characteristics: (1) they accept the harsh realities facing them, (2) they find meaning in terrible times, and (3) they are creative under pressure, making do with whatever is at hand (Coutu 2002).

Resilient organizations strive to achieve *strategic resilience*, i.e., "the ability to dynamically reinvent business models and strategies as circumstances change…and to change before the need becomes desperately obvious" (Hamel & Valiikangas 2003). An organization with this capability constantly remakes its future rather than defending its past.

Organizational resilience can be measured based on three dimensions: (1) the level of organizational situational awareness, (2) management of organizational vulnerabilities, and (3) organizational adaptive capacity (Lee, Vargo, & Seville 2013). These three items seem well accepted and appear in some form in many papers.

Preparing for the unknown is a recurring challenge of resilience. Organizations must frequently deal with adversities that were previously unknown or unknowable by developing *strategic foresight*. Strategic foresight can be developed by adopting the practice of scenario planning, where multiple adverse futures are envisioned, countermeasures are developed, and coping strategies that appear most frequently are deemed "robust" and candidates for action (Scoblic et. al. 2020). This process also trains personnel to better deal with emerging adversity.

Overview

Resilience modeling is an emerging topic in digital engineering (DE), model-based systems engineering (MBSE), and artificial intelligence/machine learning (AI/ML). Systems Engineers and developers need to identify, characterize, and accomplish trade-offs regarding cost, schedule, performance, and quality characteristics (including resilience) over the life cycle of a system. If system resilience could be accurately modeled, then quantitative (or at least qualitative) metrics could be used to evaluate a system's resilience characteristics (e.g., via a digital twin). However, no single methodology is accepted for resilience modeling of simple, complicated, or complex systems. This section examines a few potential (and evolving) modeling techniques that practitioners of resilience engineering could use.

Definition

A system resilience model represents a selective abstraction of a system to provide the required capability when facing adversity within the system and its environment. This definition of a resilience model is limited to human-made systems containing software, hardware, humans (e.g., socio-technical, organizational), infrastructures, concepts, and processes.

Potential Resilience Metrics

Please refer to the Resilience Metrics description in the "System Resilience" section.

Modeling, Measuring, & Evaluating System Resilience

Formal Methods of Constructing Models for Systems Resilience—Resilience Contracts

Madni, Erwin, & Sievers (2020) proposed resilience contracts (RCs) as an upgrade to the widely used Contract-Based Design (CBD) approach. They observed that traditional methods like Büchi automatons and Linear Temporal Logic (LTL) work for systems that behave predictably. However, many modern systems do not always behave predictably. To handle this, an RC is a mathematical model that extends CBD to account for uncertainty and unpredictability.

An RC is a mixed model that uses fixed rules and flexible assertions and is represented as a Partially Observable Markov Decision Process (POMDP). A POMDP is a special form of a Markov decision process that deals with situations where some states and transitions are not directly observable.

RCs add flexibility to deterministic contracts for systems with random elements by repeatedly checking the environment and system status, choosing the best actions to achieve a goal, and executing those actions. After each action, the system's environment and health are reassessed. The planning function then decides whether to continue with the current plan if the actions are effective or to make changes if they are not.

Application of System Dynamics

System dynamics is suitable for resilience modeling because it captures behavior over time, and resilience takes a behavior over time perspective, as shown in Figure 1 (from the System Resilience article, reproduced below). As with other types of modeling, one of the primary values of system dynamics modeling is that it can be used to build a shared understanding of the issues for all stakeholders.

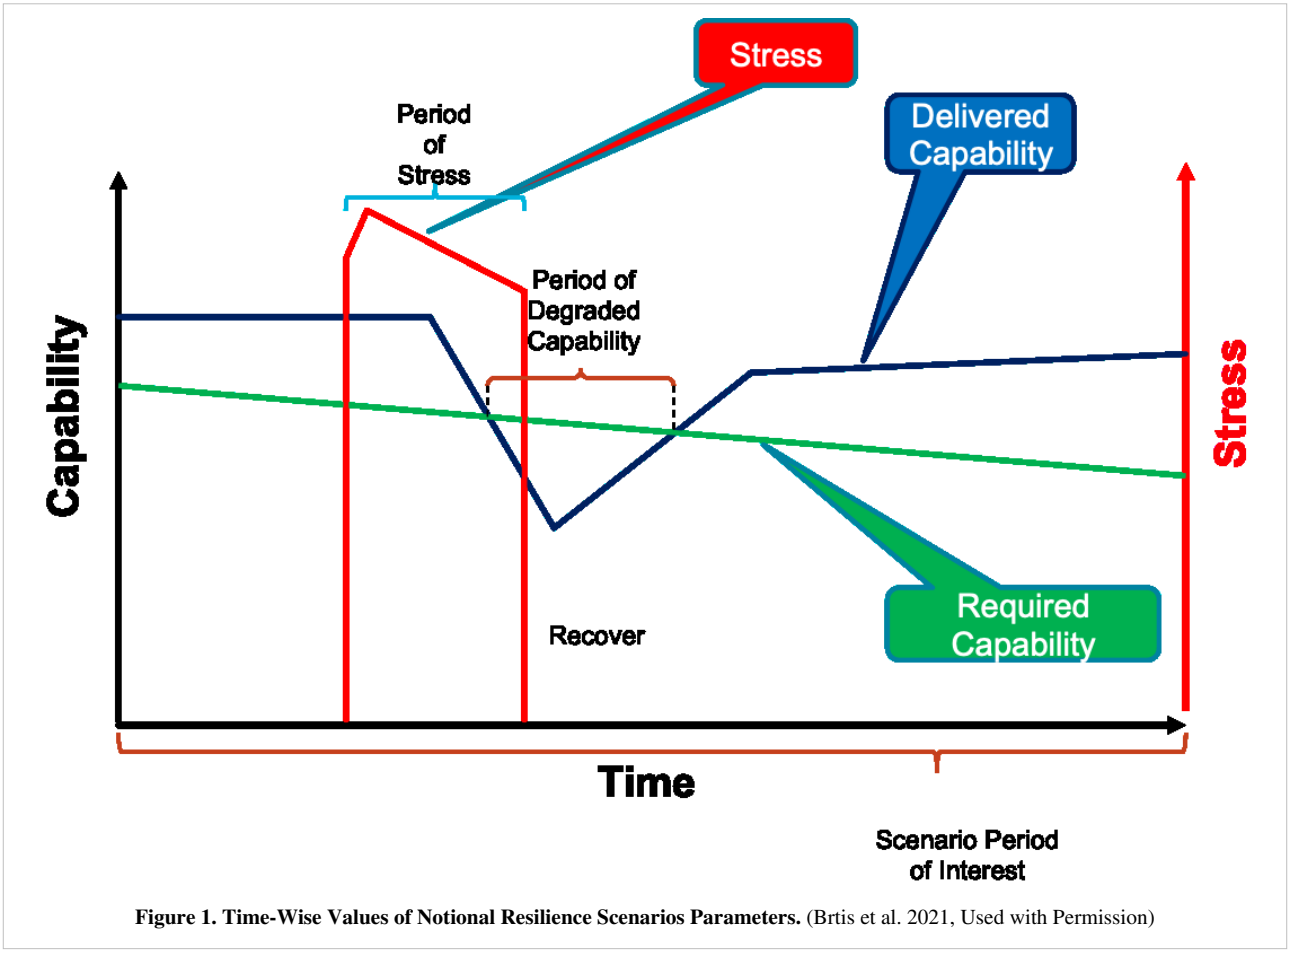

Figure 1. Time-Wise Values of Notional Resilience Scenarios Parameters. (Brtis et al. 2021, Used with Permission)

In this regard, system dynamics's long tradition of participatory model building can be uniquely valuable (Herrera & Kopainsky, 2020). These group model building activities produce causal loop diagrams, which demonstrate the feedback structure in a system in which a change in one component can ripple through the other connected components in the design and return to the original part in a reinforcing way that can lead to catastrophic failure or in a balanced way that can lead to stability and recovery from adversity.

Archetypes are another qualitative tool used in system dynamics modeling (Onyekachi, Onyeagoziri, & Ryan, 2021). In archetypes, a small set of models can examine many behavior types. In terms of resilience modeling, archetypes evaluate the feedback loops in the system that lead to both intended and unintended consequences in behavior where often the unintended consequences are not foreseen when the system is designed.

Quantitative system dynamics models have been applied to resilience modeling (Iturriza et al., 2017; Yabe et al., 2021). In this case, a highly interconnected system of first-order linear differential equations is solved using numerical methods (Radzicki & Taylor, 1997). There are two types of quantitative system dynamics models: exploratory models, which are based on theoretical behavior of a system (Taylor & Willett, 2024), and calibrated models, which use historical time-series data to estimate the model parameters (Taylor & Hossain, 2024).

Software tools can be used to build interactive models applied to resilience modeling (Iturriza et al., 2017). Using interactive models, system engineers could experiment in a virtual environment to test procedures to improve the system's Resilience under conditions that are not economical or even possible in real life.

A system's response to adversity can be analyzed using quantitative system dynamics to determine the effectiveness of the resilience processes. This is effective in learning about the impact of natural disasters on critical infrastructure (Yabe et al., 2021).

Caveats Regarding Resilience Models

Misusing models can lead to problems. It is therefore essential to use a model only for its intended purpose. Modelers must ensure the model is suitable for this purpose, check that all assumptions are valid, and ensure that no constraints are violated.

Neches & Madni (2013) suggest that modeling tools and languages should align with their intended use. Sometimes, modelers must use different tools or languages, which can cause compatibility issues. Because of this, multiple models need to be developed and made to work together, as models must cover various disciplines, aspects, and phenomena. Modelers must also create and manage different models, such as executable, depictional, and statistical models, and multiple categories, including device and environmental physics, communications, sensors, effectors, software, and systems.

Model Analysis with Consideration of Constraint Theory

Friedman & Phan (2017) point out that models face typical "well-posed" problems in mathematics. Modelers must check whether complex models are internally consistent and whether the requested calculations are mathematically allowable.

Complex models, especially those created by diverse teams, often have internal inconsistencies. Even if a model is consistent, many possible calculations might not be allowable due to over-constrained computational sets, with too many input values for the equations. On the other hand, under-constrained calculations, with too many equations and not enough values, can lead to unclear or undefined results.

Most models of complex systems include tight interaction loops called Basic Nodal Squares (BNS), which form the "kernel of intrinsic constraint." These models often have more extensive, nested interaction loops important for emergent behavior and attributes of Resilience such as adaptability, flexibility, and handling disruptions.

When computational requests that are not allowed are made on models, it often leads to incorrect predictions.

System Resistance to Electromagnetic Interference

- Lead Author:
- Paul Phister
- Contributing Authors:
- Scott Jackson, Richard Turner, John Snoderly, and Alice Squires

-

Electromagnetic Interference (EMI) is the disruption of operation of an electronic device when it is in the vicinity of an electromagnetic field in the radio frequency (RF) spectrum. Many electronic devices fail to work properly in the presence of strong RF fields. The disturbance may interrupt, obstruct, or otherwise degrade or limit the effective performance of the circuit. The source may be any object, artificial or natural, that carries rapidly changing electrical currents.

Electromagnetic Compatibility (EMC) is the ability of systems, equipment, and devices that utilize the electromagnetic spectrum to operate in their intended operational environments without suffering unacceptable degradation or causing unintentional degradation because of electromagnetic radiation or response. It involves the application of sound electromagnetic spectrum management; system, equipment, and device design configuration that ensures interference-free operation; and clear concepts and doctrines that maximize operational effectiveness (DAU 2010, Chapter 7).

Overview

Spectrum

Each nation has the right of sovereignty over the use of its spectrum and must recognize that other nations reserve the same right. It is essential that regional and global forums exist for the discussion and resolution of spectrum development and infringement issues between bordering and proximal countries that might otherwise be difficult to resolve.

The oldest, largest, and unquestionably the most important such forum, with 193 member countries, is the International Telecommunications Union (ITU) agency of the United Nations, which manages spectrum at a global level. As stated in Chapter 3 of the NTIA Manual, “The International Telecommunication Union (ITU)...is responsible for international frequency allocations, worldwide telecommunications standards and telecommunication development activities” (NTIA 2011, 3-2). The broad functions of the ITU are the regulation, coordination and development of international telecommunications.

The spectrum allocation process is conducted by many different international telecommunication geographical committees. Figure 1 shows the various international forums represented worldwide.

Figure 1. International & Regional Spectrum Management Forums. (SEBoK Original)

Assigning frequencies is very complicated, as shown in the radio spectrum allocation chart in Figure 2. Sometimes, commercial entities try to use frequencies that are actually assigned to US government agencies, such as the Department of Defense (DoD). One such incident occurred when an automatic garage door vendor installed doors on homes situated near a government installation. Random opening and closing of the doors created a problem for the vendor that could have been avoided.

Four ITU organizations affect spectrum management (Stine and Portigal 2004):

1. World Radio-communication Conference (WRC)
2. Radio Regulations Board (RRB)
3. Radio-communications Bureau (RB)
4. Radio-communication Study Groups (RSG)

The WRC meets every four years to review and modify current frequency allocations. The RB registers frequency assignments and maintains the master international register. The RRB approves the Rules of Procedures used by the BR to register frequency assignments and adjudicates interference conflicts among member nations. The SG analyzes spectrum usage in terrestrial and space applications and makes allocation recommendations to the WRC. Most member nations generally develop national frequency allocation polices that are consistent with the Radio Regulations (RR). These regulations have treaty status.

Dual Management of Spectrum in the US

Whereas most countries have a single government agency to perform the spectrum management function, the US has a dual management scheme intended to insure that

- decisions concerning commercial interests are made only after considering their impact on government systems; and
- government usage supports commercial interests.

The details of this scheme, established by the Communications Act of 1934, are as follows:

- the Federal Communications Commission (FCC) is responsible for all non-government usage
- the FCC is directly responsible to Congress;
- the president is responsible for federal government usage, and by executive order, delegates the federal government spectrum management to the National *Telecommunications and Information Administration (NTIA); and
- the NTIA is under the authority of the Secretary of Commerce.

The FCC regulates all non-federal government telecommunications under Title 47 of the Code of Federal Regulations. For example, see FCC (2009, 11299-11318). The FCC is directed by five Commissioners appointed by the president and confirmed by the Senate for five-year terms. The Commission staff is organized by function. The responsibilities of the six operating Bureaus include processing applications for licenses, analyzing complaints, conducting investigations, implementing regulatory programs, and conducting hearings (http://www.fcc.gov).

The NTIA performs spectrum management function through the Office of Spectrum Management (OSM), governed by the Manual of Regulations and Procedures for Federal Radio Frequency Management. The IRAC develops and executes policies, procedures, and technical criteria pertinent to the allocation, management, and usage of spectrum. The Spectrum Planning and Policy Advisory Committee (SPAC) reviews the reviews IRAC plans, balancing considerations of manufacturing, commerce, research, and academic interests.

Within the DoD, spectrum planning and routine operation activities are cooperatively managed. Spectrum certification is a mandated process designed to ensure that

1. frequency band usage and type of service in a given band are in conformance with the appropriate national and international tables of frequency allocations;
2. equipment conforms to all applicable standards, specifications, and regulations; and
3. approval is provided for expenditures to develop equipment dependent upon wireless communications.

Host Nation Coordination and Host Nation Approval

In peacetime, international spectrum governance requires military forces to obtain host nation permission — Host Nation Coordination (HNC)/Host Nation Approval (HNA) — to operate spectrum-dependent systems and equipment within a sovereign nation. For example, international governance is honored and enforced within the United States by the US departments of State, Defense, and the user service.

In wartime, international spectrum governance is not honored between warring countries; however, the sovereign spectrum rights of bordering countries must be respected by military forces executing their assigned missions. For example, HNA is solicited by US naval forces to use spectrum-dependent systems and equipment in bordering countries' airspace and/or on bordering countries' soil. HNA must be obtained before the operation of spectrum-dependent systems and equipment within a sovereign nation. The combatant commander is responsible for coordinating requests with sovereign nations within his or her area of responsibility. Because the combatant commander has no authority over a sovereign nation, the HNC/HNA process can be lengthy and needs to be started early in the development of a system. Figure 2 illustrates a spectrum example.

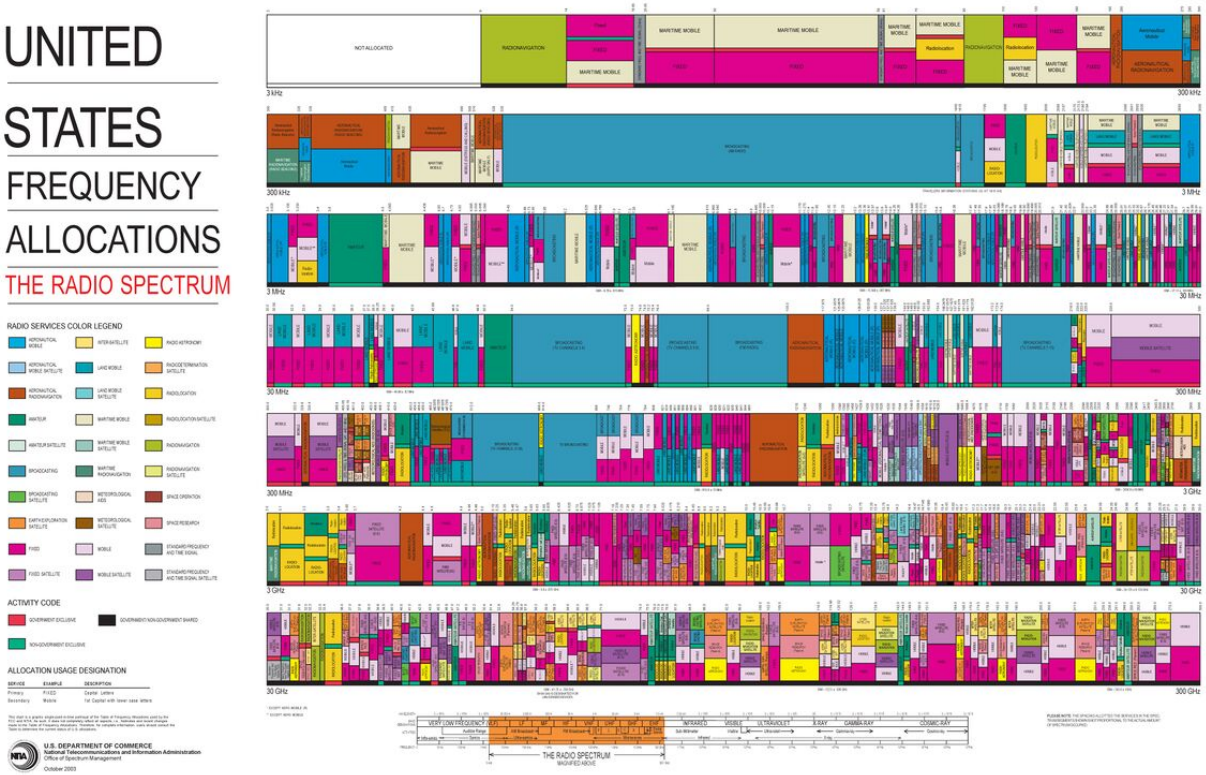

Figure 2. The Radio Spectrum (Department of Commerce 2003). Released by the U.S. Department of Commerce. Source is available at http://www.ntia.doc.gov/files/ntia/publications/2003-allochrt.pdf (Retrieved September 15, 2011)

Practical Considerations

EMI/EMC is difficult to achieve for systems that operate world-wide because of the different frequencies in which products are designed to operate in each of the telecommunication areas. Billions of US dollars have been spent in retrofitting US DoD equipment to operate successfully in other countries.

It is important to note that the nuclear radiation environment is drastically more stressing than, and very different from, the space radiation environment.

System Description

Narrowband and Broadband Emissions

To help in analyzing conducted and radiated interference effects, EMI is categorized into two types—narrowband and broadband—which are defined as follows:

- **Narrowband Emissions**

  A narrowband signal occupies a very small portion of the radio spectrum… Such signals are usually continuous sine waves (CW) and may be continuous or intermittent in occurrence… Spurious emissions, such as harmonic outputs of narrowband communication transmitters, power-line hum, local oscillators, signal generators, test equipment, and many other man made sources are narrowband emitters. (Bagad 2009, G-1)

- **Broadband Emissions**

  A broadband signal may spread its energy across hundreds of megahertz or more… This type of signal is composed of narrow pulses having relatively short rise and fall times. Broadband signals are further

> *divided into random and impulse sources. These may be transient, continuous or intermittent in occurrence. Examples include unintentional emissions from communication and radar transmitters, electric switch contacts, computers, thermostats, ignition systems, voltage regulators, pulse generators, and intermittent ground connections.* (Bagad 2009, G-1)

TEMPEST

TEMPEST is a codename used to refer to the field of emission security. The National Security Agency (NSA) investigations conducted to study compromising emission (CE) were codenamed TEMPEST. National Security Telecommunications Information Systems Security Issuance (NSTISSI)-7000 states:

> *Electronic and electromechanical information-processing equipment can produce unintentional intelligence-bearing emanations, commonly known as TEMPEST. If intercepted and analyzed, these emanations may disclose information transmitted, received, handled, or otherwise processed by the equipment.* (NSTISS 1993, 3)

These compromising emanations consist of electrical, mechanical, or acoustical energy intentionally or unintentionally emitted by sources within equipment or systems which process national security information. Electronic communications equipment needs to be secured from potential eavesdroppers while allowing security agencies to intercept and interpret similar signals from other sources. The ranges at which these signals can be intercepted depends upon the functional design of the information processing equipment, its installation, and prevailing environmental conditions.

Electronic devices and systems can be designed, by means of Radiation Hardening techniques, to resist damage or malfunction caused by ionizing and other forms of radiation (Van Lint and Holmes Siedle 2000). Electronics in systems can be exposed to ionizing radiation in the Van Allen radiation belts around the Earth's atmosphere, cosmic radiation in outer space, gamma or neutron radiation near nuclear reactors, and electromagnetic pulses (EMP) during nuclear events.

A single charged particle can affect thousands of electrons, causing electronic noise that subsequently produces inaccurate signals. These errors could affect safe and effective operation of satellites, spacecraft, and nuclear devices. Lattice displacement is permanent damage to the arrangement of atoms in element crystals within electronic devices. Lattice displacement is caused by neutrons, protons, alpha particles, and heavy ions. Ionization effects are temporary damages that create latch-up glitches in high power transistors and soft errors like bit flips in digital devices. Ionization effects are caused by charged particles.

Most radiation-hardened components are based on the functionality of their commercial equivalents. Design features and manufacturing variations are incorporated to reduce the components' susceptibility to interference from radiation. Physical design techniques include insulating substrates, package shielding, chip shielding with depleted boron, and magneto-resistive RAM. Logical design techniques include error-correcting memory, error detection in processing paths, and redundant elements at both circuit and subsystem levels (Dawes 1991). Nuclear hardness is expressed as susceptibility or vulnerability for given environmental conditions. These environmental conditions include peak radiation levels, overpressure, dose rates, and total dosage.

System Safety

- Lead Author:
- Dick Fairley
- Contributing Authors:
- Art Pyster and Alice Squires

-

In the most general sense, safety is freedom from harm. As an engineering discipline, system safety is concerned with minimizing hazards that can result in a mishap with an expected severity and with a predicted probability. These events can occur in elements of life-critical systems as well as other system elements. MIL-STD-882E defines system safety as “the application of engineering and management principles, criteria, and techniques to achieve acceptable risk, within the constraints of operational effectiveness and suitability, time, and cost, throughout all phases of the system life cycle" (DoD 2012). MIL-STD-882E defines standard practices and methods to apply as engineering tools in the practice of system safety. These tools are applied to both hardware and software elements of the system in question.

Overview

System safety engineering focuses on identifying hazards, their causal factors, and predicting the resultant severity and probability. The ultimate goal of the process is to reduce or eliminate the severity and probability of the identified hazards, and to minimize risk and severity where the hazards cannot be eliminated. MIL STD 882E defines a hazard as "a real or potential condition that could lead to an unplanned event or series of events (i.e., mishap) resulting in death, injury, occupational illness, damage to or loss of equipment or property, or damage to the environment." (DoD 2012).

While systems safety engineering attempts to minimize safety issues throughout the planning and design of systems, mishaps do occur from combinations of unlikely hazards with minimal probabilities. As a result, safety engineering is often performed in reaction to adverse events after deployment. For example, many improvements in aircraft safety come about as a result of recommendations by the U.S. National Air Traffic Safety Board based on accident investigations. Risk is defined as “a combination of the severity of the mishap and the probability that the mishap will occur" (DoD 2012). Failure to identify risks to safety and the according inability to address or "control" these risks can result in massive costs, both human and economic (Roland and Moriarty 1990)."

Personnel Considerations

System Safety Specialists are typically responsible for ensuring system safety. Chapter 11 of Air Force Instruction (AFI) 191-202 (USAF 2020) is a lengthy exposition of the responsibilities of system safety specialists. AFI 191-202 defines system safety as "the application of engineering and management principles, criteria and techniques to achieve acceptable risk within the constraints of operational effectiveness and suitability, time and cost throughout all phases of the system life cycle." The AFI identifies eight activities to achieve systems safety:

1. Documenting the system safety approach
2. Hazard identification and analysis over the system life cycle
3. Assessment of risk, expressed as severity and probability of consequences
4. Identification and assessment of potential risk mitigation measures
5. Implementation of measures to reduce risks to acceptable levels
6. Verification of risk reduction
7. Acceptance of risks by appropriate authorities
8. Tracking of hazards and risks throughout the system life cycle

Although these activities are documented in an Air Force Instruction, they are actually quite generic and applicable to almost any system safety process.

Safety personnel are responsible for the integration of system safety requirements, principles, procedures, and processes into the program and into lower system design levels to ensure a safe and effective interface. Two common mechanisms are the Safety Working Group (SWG) and the Management Safety Review Board (MSRB). The SWG enables safety personnel from all integrated product teams (IPTs) to evaluate, coordinate, and implement a safety approach that is integrated at the system level in accordance with MIL-STD-882E (DoD 2012). Increasingly, safety reviews are being recognized as an important risk management tool. The MSRB provides program level oversight and resolves safety related program issues across all IPTs.

Table 1 provides additional information on safety.

Table 1. Safety Ontology. (SEBoK Original)

Ontology Element Name	Ontology Element Attributes	Relationships to Safety
Failure modes	Manner of failure	Required attribute
Severity	Consequences of failure	Required attribute
Criticality	Impact of failure	Required attribute
Hazard Identification	Identification of potential failure modes	Required to determine failure modes
Risk	Probability of a failure occurring	Required attribute
Mitigation	Measure to take corrective action	Necessary to determine criticality and severity

Table 1 indicates that achieving system safety involves a close tie between Safety Engineering and other specialty Systems Engineering disciplines such as System Reliability, Availability, and Maintainability.

System Security

- Lead Author:
- Mark Winstead
- Contributing Authors:
- Terri Chan and Keith Willett

-

Security is freedom from those conditions that may lead to loss of assets (anything of value) with undesired consequences (Ross, Winstead, & McEvilley 2022). Systems Security specifically is concerned with systems delivering capability (an asset) with intended and only intended behaviors and outcomes (no unacceptable consequences such as loss of asset integrity) in contested operational environments (cyberspace or physical).

Restated, Systems Security is about engineering for intended and authorized system behavior and outcomes despite anticipated and unanticipated adversity, conditions that may cause loss (e.g., threats, attacks, hazards, disruptions, exposures). (McEvilley & Winstead 2022)

Note: This is a completely new article inserted in SEBoK 2.9, replacing the previous version by Richard Fairley, Alice Squires, and Keith Willett which originally appeared in SEBoK 1.0 and was periodically updated through SEBoK 2.8.

Overview

Secure systems ideally have three essential characteristics (Ross, Winstead, & McEvilley 2022):

- Enable required system capability delivery despite intentional and unintentional forms of adversity.
- Enforce constraints to ensure only the desired behaviors and outcomes associated with the required capability are realized while realizing the first characteristic.
- Enforce constraints based on a set of rules defining the only authorized interactions and operations allowed to occur while satisfying the second characteristic.

Desired behaviors and outcomes are those reflecting the delivery of the desired system capabilities and features without experiencing loss with undesired consequences, such as loss of information privacy.

While these characteristics are to be achieved to the extent practicable, gaps will occur between the ideal and what can be dependably achieved. A system should be as secure as reasonably practical (ASARP) while meeting minimum stakeholder expectations for security and optimized among other performance objectives and constraints, informed by the principle of commensurate trustworthiness – trustworthy to a level commensurate with the most significant adverse effect resulting from loss or failure. (Hild, McEvilley, & Winstead 2021)

Secure systems ideally have three essential characteristics (Ross, Winstead, & McEvilley 2022):

- Enable required system capability delivery despite intentional and unintentional forms of adversity.

- Enforce constraints to ensure only the desired behaviors and outcomes associated with the required capability are realized while realizing the first characteristic.
- Enforce constraints based on a set of rules defining the only authorized interactions and operations allowed to occur while satisfying the second characteristic.

Desired behaviors and outcomes are those reflecting delivery of the desired system capabilities and features without experiencing loss with undesired consequences, such as loss of information privacy.

While these characteristics are to be achieved to the extent practicable, gaps will occur between the ideal and what can be dependably achieved. A system should be as secure as reasonably practical (ASARP) while meeting minimum stakeholder expectations for security and optimized among other performance objectives and constraints, informed by the principle of commensurate trustworthiness – trustworthy to a level commensurate with the most significant adverse effect resulting from loss or failure. (Hild, McEvilley, & Winstead 2021)

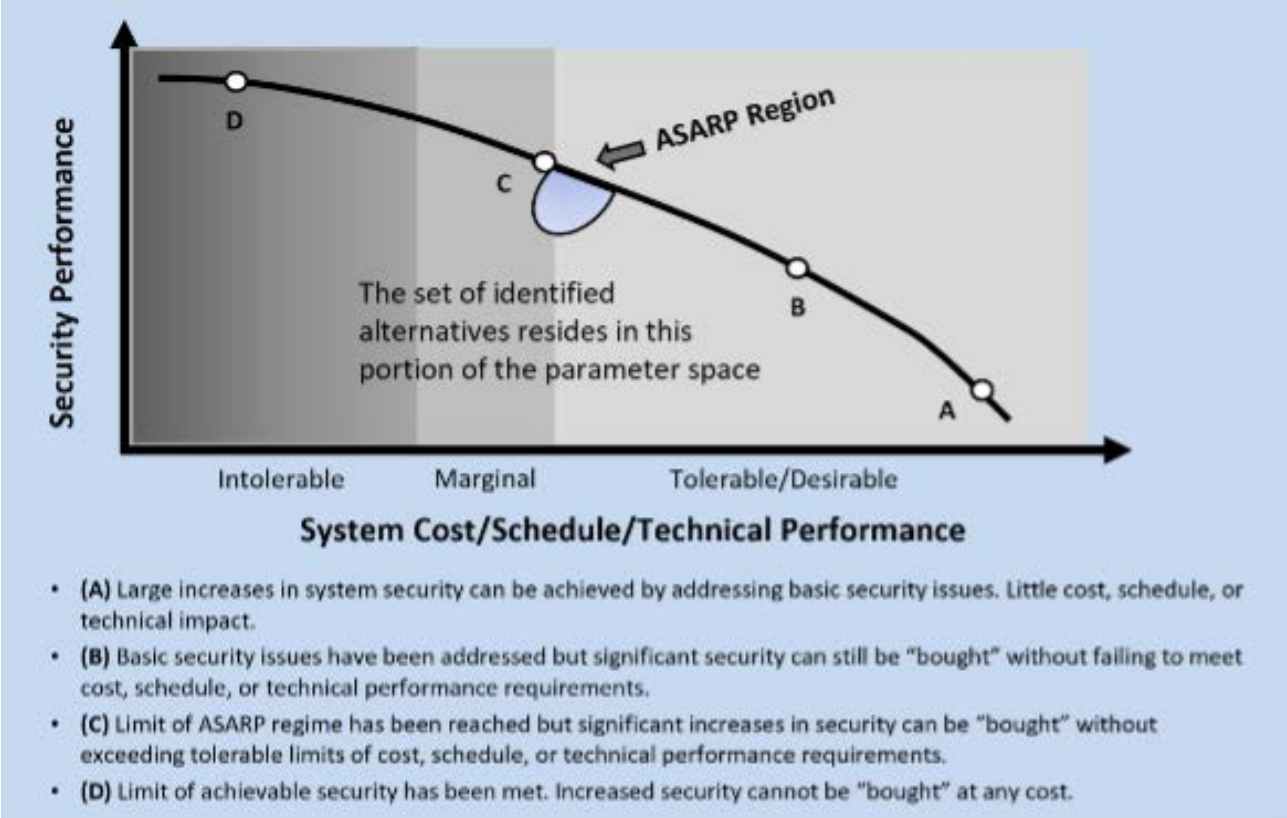

Figure 1. System Security and Cost/Schedule/other Performance (Ross, Winstead, & McEvilley, 2022 - Public Domain)

To understand the optimization of security among other performance objectives, stakeholders need to be aligned and respectful of each other's needs. As loss and loss effects or consequences are easily understood, a collaborative understanding of loss tolerances provides a means to alignment as well as forms a basis for metrics across the system lifecycle. (Dove, et al. 2023)

Why Security?

Security, one of 10 acknowledged areas of growing stakeholder expectations in INCOSE's Systems Engineering Vision 2035, is recognized as needed to become a foundational perspective for system design. (INCOSE 2021) This growing expectation is motivated by increasing cyberspace-based attacks as evidenced by reports such as Security Magazine's report for computers with Internet access, an attack occurred every 39 seconds in 2017 and has increased since (Security 2017) by observations from the conflict in Ukraine (Carnegie Endowment for International Peace 2023) including attacks on civilian targets such as critical infrastructure, and many well-publicized exploited

vulnerable systems. (Agile IT 2023)

Scope

Adversity, conditions that can cause a loss of assets (e.g., threats, attacks, vulnerabilities, hazards, disruptions, and exposures), occurs throughout the system lifecycle. Such conditions are internal and external to the system, with internal conditions often the result of faults and defects (e.g., missing requirements, implementation errors). Consequently, system security's scope matches systems engineering's scope, and every systems engineering process and activity has security considerations. (Ross, Winstead, & McEvilley 2022)

"Unless security is [engineered] into a system from its inception, there is little chance that it can be made secure by retrofit". (Anderson 1972) Consequently, security must be a foundational perspective from concept exploration.

Assets

An asset is an item of value to a stakeholder. Ross, Winstead, & McEvilley (2022) identified broad asset classes, summarized in Table 1.

Table 1. Common Asset Classes (Ross, Winstead, and McEvilley, 2022 - Public Domain)

Class	Description	Loss Protection Criteria
Material Resources and Infrastructure	Includes • physical property (e.g., buildings, facilities, equipment) • physical resources (e.g., water, fuel). • basic physical and organizational structures and facilities (i.e., infrastructure) needed for an activity or the operation of an enterprise or society. An infrastructure commonly comprised of assets, such as a nation's national airspace infrastructure, which includes the nation's airports	*Material resources* are protected from loss if they are not stolen, damaged, or destroyed or are able to function or be used as intended, as needed, and when needed. *Infrastructure* is protected from loss if it meets performance expectations while delivering only the authorized and intended capability and producing only the authorized and intended outcomes
System Capability	The set of capabilities and services provided by a system	*System capability* is protected from loss when it meets its performance expectations while delivering only the authorized and intended capability and producing only the authorized and intended outcomes.
Human Resources	Personnel who are part of the system and personnel affected by the system	*Human resources* are protected from loss if they are not injured, suffer illness, or killed.
Intellectual Property	Trade secrets, recipes, technology, and other items that constitute an advantage over competitors	*Intellectual property* is protected from loss if it is not stolen, corrupted, destroyed, copied, substituted in an unauthorized manner, or reverse-engineered in an unauthorized manner.
Data and Information	Includes all types of data and information and all encodings and representations of data and information	*Data and information* are protected from loss due to unauthorized alteration, exfiltration, infiltration, and destruction.
Derivative Non-Tangible	Includes image, reputation, and trust. Such assets are affected by the success or failure to protect other assets	*Non-tangible assets* are protected from loss by ensuring the adequate protection of assets in the other classes.

Systems Thinking

Systems thinking is the practice of thinking holistically about systems: relating systems behaviors and concepts to principles based on patterns. It is flexible, conceptual, and strategic in nature: hence generally adapted in systems architecture work. Systems thinking focuses not on immediate cause and effect, but also examines the dynamics of a system to identify secondary effects on behaviors and choices. (Goodman 2018)

Security, especially cybersecurity, has suffered from being treated as a tactics problem, focusing on threat defense and incident response. Security has also become a forensics exercise, steeped in root cause analysis, to add to the known threat defense. Systems thinking realizes the greater objective is assuring a systems' ability to produce the capability (functions and services) that users depend on the system for and contributing to business and mission needs and produce that capability in an acceptable manner (i.e., no harm to stakeholder assets). The need is to focus less on efforts to defend against adversarial action beyond the control of the systems engineer and more on assuring the system performs and protects stakeholder assets, controlling the system from effects of loss, to include avoiding vulnerability that leads to loss when practical. (Young & Leveson 2013) Systems thinking brings security back into the conceptual, design, and implementation of systems capabilities.

Consequently, the need is to focus on a system's trustworthiness rather than singularly focus on risk. (Dove, et al. 2021) Quality evidence such as that generated by verification and validation activities feed assurance arguments that merit trustworthiness, providing a basis for trust by stakeholders. Without such assurance, security functionality is a form of veneer security (Saydjari 2018), providing an unmerited sense of trustworthiness.

Loss

Loss, the experience of having an asset taken away or destroyed or the failure to keep or to continue to have an asset in a desired state or form (Ross, Winstead, & McEvilley 2022), provides language understood by all stakeholders (Dove, et al. 2023). Stakeholder concern is typically the effects of loss caused by adversity, not the adversity itself, and their priorities driven by consequences (e.g., impact to mission). Their needs and requirements can thus be expressed in terms of loss, loss scenarios, loss tolerance, and acceptable loss.

Addressing loss must consider loss results from combinations of adverse events or conditions that cause or lead to unacceptable ramifications, consequences, or impacts. Due to uncertainty (including uncertainty about adversity), guaranteeing a loss will not occur is not possible. The focus must be on controlling loss effects, including cascading or ripple events; e.g., the effect causes additional losses to occur. (Ross, Winstead, & McEvilley 2022)

Loss control objectives frame addressing loss. Loss can be addressed by use of historically-informed practices (known good things to do) and assessing specific loss scenarios for opportunities to address conditions and the potential loss itself.

Table 2. Los Control Objectives (Ross, Winstead, and McEvilley, 2022 - Public Domain)

Loss Control Objective	Discussion

Prevent the Loss from Occurring	*Loss is avoided. Despite the presence of adversity:
	• The system provides only the intended behavior and produces only the intended outcomes.
	• Desired properties of the system and assets are retained.
	• Achieved by combinations of:
	  • Preventing or removing the event or events that cause the loss
	  • Preventing or removing the condition or conditions that allow the loss to occur
	  • Not suffering an adverse effect despite the events or conditions (e.g., fault tolerance)

Limit the Extent of Loss	*Loss can or has occurred. The loss effect extent is to be limited.

- Achieved by combinations of:
  - Limiting dispersion (e.g., propagation, ripple, or cascading effects)
  - Limiting duration (e.g., milliseconds, minutes, days)
  - Limiting capacity (e.g., diminished service or capability)
  - Limiting volume (e.g., bits or bytes of data/information)
- Decisions to limit loss extent may require prioritizing what constitutes acceptable loss across a set of losses (i.e., limiting the loss of one asset requires accepting loss of some other asset).
- Loss recovery and loss delay are two means to limit loss:
  - Loss Recovery: Action is taken by the system or enabled by the system to recover (or allow the recovery of) some or all its ability to function and to recover assets used by the system. Asset restoration can limit the dispersion, duration, capacity, or volume of the loss.
  - Loss Delay: The loss event is avoided until the adverse effect is lessened or when a delay enables a more robust response or quicker recovery.

Loss Scenarios

Loss scenarios describe the events and conditions that lead to unacceptable outcomes. These scenarios do not necessarily lead back to “root causes” in each case, but must capture the internal system (e.g., system states, internal faults) and the external environmental conditions (e.g., loss of power, presence of malicious insider threat) that may lead to a loss, including unauthorized system use (e.g., loss of control). See Figure 2.

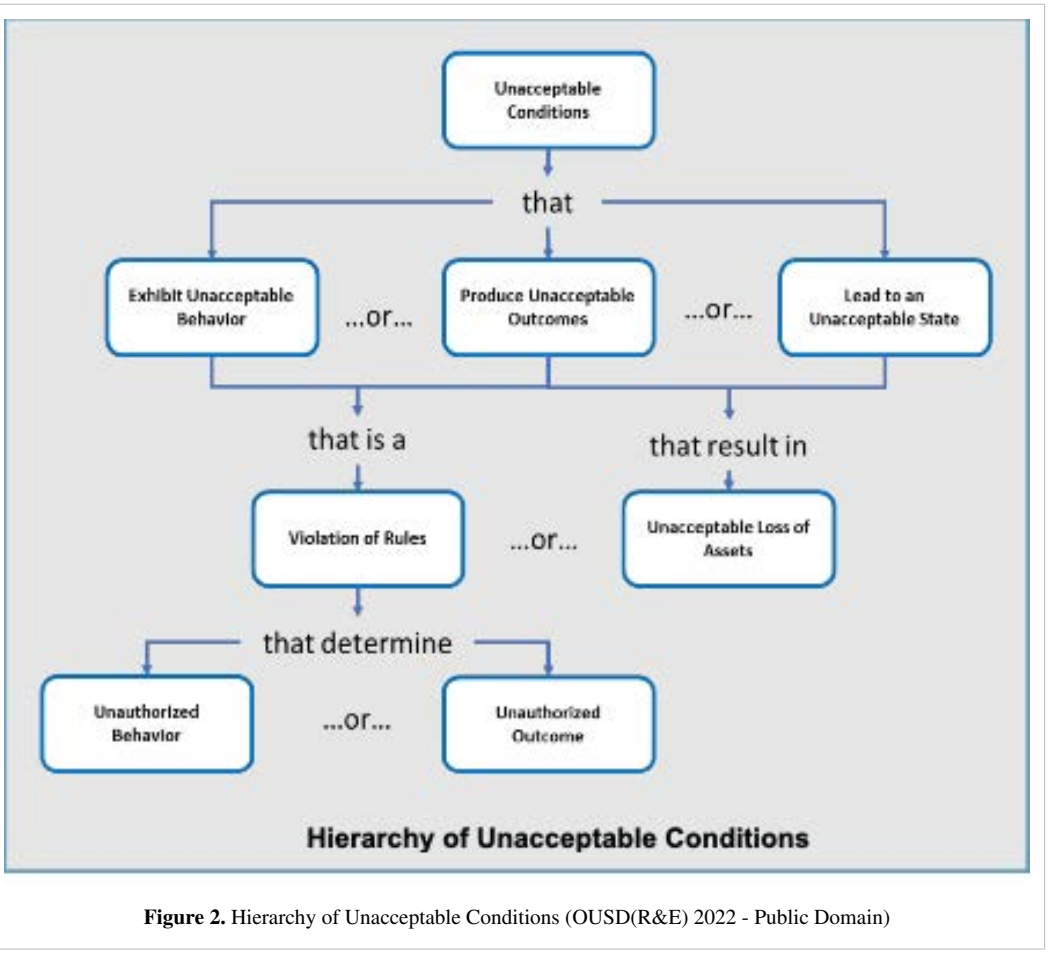

Figure 2. Hierarchy of Unacceptable Conditions (OUSD(R&E) 2022 - Public Domain)

Loss scenarios may be analyzed to inform requirements definition and derivation and analyze design alternatives, as well as inform tailoring of historically-informed practice usage.

Enterprise Relationships

Most systems are part of a larger system of systems or enterprises. Adversity often comes through or from these connected systems.

Systems engineering must balance a system's self-protection capability with opportunities for mutual collaborative protection (Dove, et al. 2021) with trustworthy systems within an enterprise. Enterprises may have dedicated systems for protection, often within network operations and security centers (NOSCs). (Knerler, Parker, & Zimmerman 2022) Systems may also collaborate by sharing situational awareness, with one system alerting others of suspicious activity that may indicate malicious actions others may experience.

Discipline Relationships

Systems Security has commonality and synergy with many other disciplines, such as safety; quality management; reliability, availability, and maintenance (RAM); survivability; operational risk management; and resilience. Overlapping concerns exist with assets, losses, and adversities considered; requirements; and various engineering processes and analyses similarities and opportunities; e.g., System Theoretic Process Analysis, or STPA (Young & Leveson 2013). Some considerations for pursuing these commonalities and synergies were explored in Brtis (2020).

Personnel Considerations

Systems security engineering is a sub-discipline of systems engineering, defined in Ross, Winstead, & McEvilley (2022) as a transdisciplinary and integrative approach to enable the successful secure realization, use, and retirement of engineered systems using systems, security, and other principles and concepts, as well as scientific, technological, and management methods. Systems security engineers are part of the systems engineering teams.

But as security is demonstrated in a system's behaviors and outcomes, systems engineering responsibility, the systems engineer is ultimately responsible for a system's security. (Thomas 2013) However, reflecting the maxim "Security is everyone's job", all engineering disciplines have security responsibilities (Dove, et al. 2021), not just the systems engineer and various specialists in areas like supply chain assurance, hardware assurance, software assurance, cybersecurity, and physical security.

Security in the Future of Systems Engineering

The INCOSE SE Vision 2035 sets an aim that security "will be as foundational a perspective in systems design as system performance and safety are today". (INCOSE 2021) To that end and other aims for security within the Vision, the INCOSE Systems Security Engineering Working Group has set objectives and roadmap concepts (Dove 2022).

Roadmap Concept	General Needs to Fill
Security Proficiency in the Systems Engineering Team	System security and its evolution effectively enabled by systems engineering activity.
Education and Competency Development	Education at all levels focused on security of cyber-physical systems.
Stakeholder Alignment	Common security vision and knowledge among all stakeholders.
Loss-Driven Engineering	Standard metrics and abstractions relevant to all system lifecycle phases.
Architectural Agility	Readily composable and re-composable security with feature variants.
Operational Agility	Ability for cyber-relevant response to attack and potential threat; resilience in security system.
Capability-Based Security Engineering	Top-down approach to security starting with desired results/value.
Security as a Functional Requirement	Systems engineering responsibility for the security of systems.

Modeled Trustworthiness	Reinvigorate formal modeling of system trust as a core aspect of system security engineering; address issues of scale with model-based tools and automation.
Security Orchestration	Tightly coupled coordinated system defense in cyber-relevant time.
Collaborative Mutual Protection	Augmented detection and mitigation of known and unknown attacks with components collaborating for mutual protection.

Challenges

The challenging problems for system security are numerous. Some of this is a result of neglecting the addressing of security early in the system life cycle as recognized by the Systems Engineering Vision call for security to be a foundational perspective – as Carl Landwehr wrote "This whole economic boom in [security] seems largely to be a consequence of poor engineering" (Landwehr 2015).

For example, system of systems engineering security faces challenges in part to not knowing or trusting the component systems which may not have been engineered with security in mind, or at least did not consider documenting the evidence that informs trustworthiness. Another system of systems challenge comes as formerly isolated cyber-physical systems (CPSs) are increasingly connected to form larger system of systems, negating assumptions impacting security if security was considered at all. Additionally, legacy CPSs were not built thinking of the need to update the software; i.e. use sustainable security (Rosser 2023)), which creates a challenge in upgrading software to reflect revised assumptions and security models for the CPS in question.

Another challenge comes with the advancing use of Artificial Intelligence (AI). Any new technology presents security challenges until its usage matures, but AI introduces complexity and decreases predictability (INCOSE 2021). Managing complexity and uncertainty is necessary for security (Ross, Winstead, & McEvilley 2022), and AI increasing of both compounds the problem space for systems engineering security.

Videos

Keith Willett previously authored a series of videos that explain aspects of systems security. They are not referenced in the above article, but remain quite relevant and interesting viewing.

Part 7: SE Implementation Examples

Systems Engineering Implementation Examples

Contents of this Part

- Matrix of Implementation Examples (Heidi Davidz, Alice Squires, and Tom Hilburn) (Alex Lee, John Brackett, and Richard Turner)
- Implementation Examples
- Defense System Examples
- Information System Examples
- Management System Examples
- Medical System Examples
- Space System Examples
- Transportation System Examples
- Utilities Examples
- Lead Authors:
- Heidi Davidz and Richard Turner

-

Part 7 is a collection of systems engineering (SE) implementation examples to illustrate the principles described in the Systems Engineering Body of Knowledge (SEBoK) Parts 1-6. These examples describe the application of SE practices, principles, and concepts in real settings.

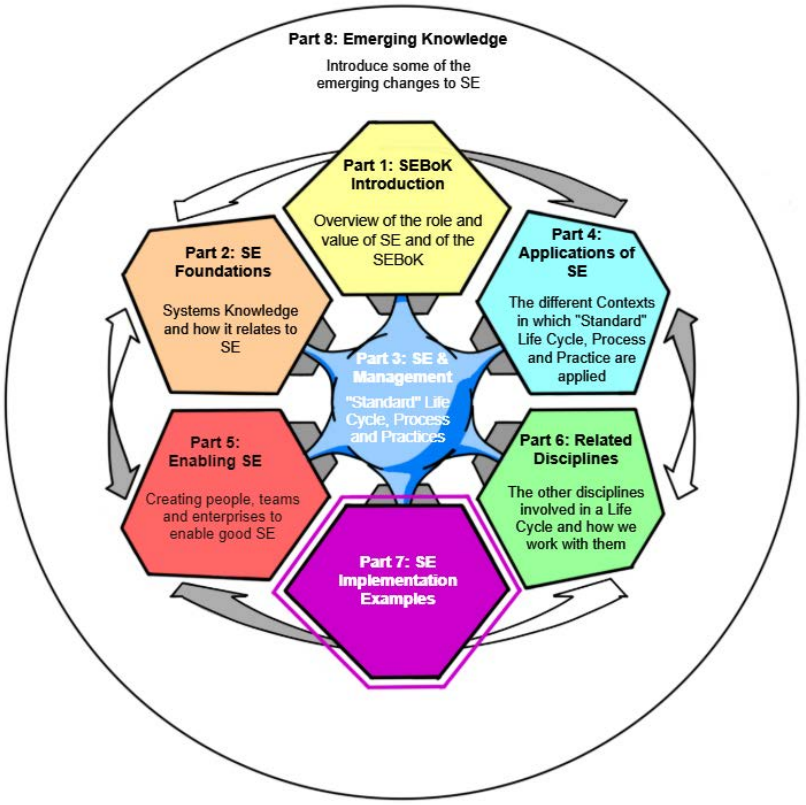

Figure 1 SEBoK Part 7 in context (Modified from Adcock et al. 2016). For more detail see Structure of the SEBoK

The intent is to provide typical instances of the application of systems engineering (SE) and relate these to key SE principles and concepts from the rest of the SEBoK. This can improve the practice of SE by illustrating to students, educators, and practitioners the benefits of effective practice, as well as the risks and liabilities of poor practice.

A published case study will typically describe aspects of the practice of SE in a particular situation and then provide comments and critique of that practice. Where possible, examples in the SEBoK refer to published case studies and relate the discussions in them to appropriate areas of the SEBoK. In some case, good or bad examples of SE practice are available but have not been documented in a case study. In these cases the SEBoK authors have described and commented on these examples directly.

A matrix of implementation examples is used to map these examples to main topics in the SEBoK which they cover.

More examples will be added over time to highlight the different aspects and applications of SE. In addition, new examples can be added to demonstrate the evolving state of practice, such as the application of model-based SE and the engineering of complex, adaptive systems.

Knowledge Areas in Part 7

Part 7 is organized in the following way:

- Matrix of Implementation Examples
- Implementation Examples

Value of Implementation Examples

Learning from critical examples has been used for decades in medicine, law, and business to help students learn fundamentals and to help practitioners improve their practice. A Matrix of Implementation Examples is used to show the alignment of systems engineering case studies to specific areas of the SEBoK. This matrix is intended to provide linkages between each implementation example to the discussion of the systems engineering principles illustrated. The selection of examples covers a variety of sources, domains, and geographic locations. Both effective and ineffective use of systems engineering principles are illustrated.

The United States Air Force Center for Systems Engineering (AF CSE) has developed a set of case studies "to facilitate learning by emphasizing the long-term consequences of the systems engineering/programmatic decisions on cost, schedule, and operational effectiveness." (USAF Center for Systems Engineering 2011) The AF CSE is using these cases to enhance SE curriculum. The cases are structured using the Friedman-Sage framework (Friedman and Sage 2003; Friedman and Sage 2004, 84-96), which decomposes a case into contractor, government, and shared responsibilities in the following nine concept areas:

1. Requirements Definition and Management
2. Systems Architecture Development
3. System/Subsystem Design
4. Verification/Validation
5. Risk Management
6. Systems Integration and Interfaces
7. Life Cycle Support
8. Deployment and Post Deployment
9. System and Program Management

This framework forms the basis of the case study analysis carried out by the AF CSE. Two of these case studies are highlighted in this SEBoK section, the Hubble Space Telescope Case Study and the Global Positioning System Case Study.

The United States National Aeronautics and Space Administration (NASA) has a catalog of more than fifty NASA-related case studies (NASA 2011). These case studies include insights about both program management and systems engineering. Varying in the level of detail, topics addressed, and source organization, these case studies are used to enhance learning at workshops, training, retreats, and conferences. The use of case studies is viewed as important by NASA since "organizational learning takes place when knowledge is shared in usable ways among organizational members. Knowledge is most usable when it is contextual" (NASA 2011). Case study teaching is a method for sharing contextual knowledge to enable reapplication of lessons learned. The MSTI Case Study is from this catalog.

Matrix of Implementation Examples

- Lead Authors:
- Heidi Davidz, Alice Squires, and Tom Hilburn
- Contributing Authors:
- Alex Lee, John Brackett, and Richard Turner

-

The following matrix maps the Systems Engineering Implementation Examples to topics in the Systems Engineering Body of Knowledge (SEBoK). It provides both a list of systems engineering implementation examples for topics of interest, and a list of relevant topics for each implementation example. Since the number of topics in the SEBoK is extensive, only a subset is included here for clarity. For additional information, see the example of interest and the corresponding SEBoK topic.

Organization and Mapping of Examples to the SEBoK

The following short titles shown in Table 1 are used for the implementation examples:

Table 1. Short Titles for the SEBoK Examples. (SEBoK Original)

Case Studies	
BT	Business Transformation
ATC	NextGen Air Traffic Control
NASA	NASA's Mission to Saturn
HST	Hubble Space Telescope
GPS	Global Positioning System
GPS II	Global Positioning System II
Radiation	Medical Radiation
FBI VCF	FBI Virtual Case File System
MSTI	Miniature Seeker Technology Integration
Infusion Pump	Next Generation Medical Infusion Pump
DfM	Design for Maintainability
CAS	Complex Adaptive Operating System
PM	Project Management
TS	Taxi Service
SWFTS	SWFTS MBSE
Bag Handling	Denver Airport Baggage Handling System
VA Sub	Virginia Class Submarine
Route Mod	UK West Coast Route Modernisation Project
Water Mgmt	Singapore Water Management
FAA AAS	FAA Advanced Automation System
Light Rail	Standard Korean Light Transit System
TMT	Thirty-Meter Telescope

Implementation Examples

-

Characteristics of the organization(s) which perform SE have an impact on the engineering itself. It is for this reason that the examples are grouped into three categories: government examples, commercial examples, and examples which represent issues from both ("combined"). As the SEBoK continues to evolve, additional categorizations may be developed. A matrix is used to map the specific systems engineering principles illustrated in each example to the associated SEBoK topics.

Characterization of Examples

Systems engineering (SE) principles described in the SEBoK Parts 1-6 are illustrated in Part 7, Systems Engineering Implementation Examples. These examples describe the application of systems engineering practices, principles, and concepts in real settings and can be used to improve the practice of systems engineering by illustrating to students, practitioners, and those new to SE the benefits of effective practice and the risks of poor practice.

The examples here have been developed by examining previously published case studies from external sources that demonstrate the real-world examples of systems engineering principles. These case studies were then summarized by the BKCASE team. The summaries include links to the original documentation as well as links to the relevant areas of the SEBoK highlighted in the example.

Systems engineering (SE) examples can be characterized in terms of at least two relevant parameters, viz., their degrees of complexity and engineering difficulty. Although a so-called quad chart is likely an oversimplification, a 2 x 2 array can be used to make a first-order characterization, as shown in Figure 1.

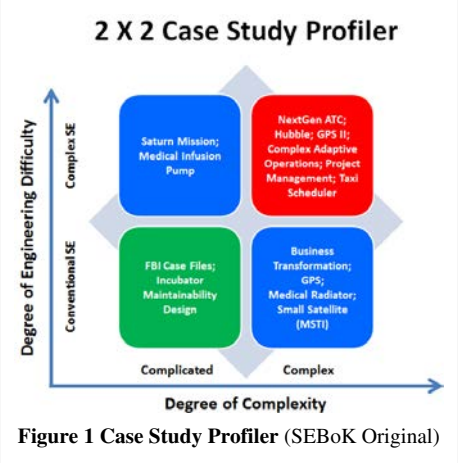

Figure 1 Case Study Profiler (SEBoK Original)

The x-axis depicts complicated, the simplest form of complexity, at the low-end on the left, and complex, representing the range of all higher forms of complexity on the right. The y-axis suggests how difficult it might be to engineer (or re-engineer) the system to be improved, using Conventional (classical or traditional) SE, at the low-end on the bottom, and Complex SE, representing all more sophisticated forms of SE, on the top. This upper range is intended to cover system of systems (SoS) engineering (SoSE), enterprise systems engineering (ESE), as well as Complex SE (CSE).The distinctions among these various forms of SE may be explored by visiting other sections of the SEBoK. In summary, the SEBoK case study editors have placed each case study in one of these four quadrants to provide readers with a suggested characterization of their case study's complexity and difficulty. For sake of compactness the following abbreviations have been used:

- Business Transformation (Successful Business Transformation within a Russian Information Technology Company)
- NextGen ATC (Federal Aviation Administration Next Generation Air Transportation System)
- Saturn Mission (How Lack of Information Sharing Jeopardized the NASA/ESA Cassini/Huygens Mission to Saturn)
- Hubble (Hubble Space Telescope Case Study)
- GPS and GPS II (Global Positioning System Case Study)
- Medical Radiator (Medical Radiation Case Study)
- FBI Case Files (FBI Virtual Case File System Case Study)
- Small Satellite MSTI (MSTI Case Study)
- Medical Infusion Pump (Next Generation Medical Infusion Pump Case Study)
- Incubator Maintainability Design (Design for Maintainability)
- Complex Adaptive Operations (Complex Adaptive Operating System)
- Taxi Scheduler (The Development of the First Real-Time Complex Adaptive Scheduler for a London Taxi Service)
- Project Management (The Development of a Real-Time Complex Adaptive Project Management System)
- SWFTS MBSE (Submarine Warfare Federated Tactical Systems Case Study)

Defense System Examples

Submarine Warfare Federated Tactical Systems

-

This article describes the transformation of the systems engineering and integration program that produces the common combat system used across the United States Navy (USN) submarine fleet from traditional document-based systems engineering (DBSE) to model-based systems engineering (MBSE).. The topic may be of particular interest to those dealing with programs in the sustainment and evolution phase of their life cycle. For addition information, refer to the links provided in Section V, Lessons Learned below.

Background

Modern submarines are typically in service for 20 - 40 years. Historically, each new class of submarines has been equipped with a new combat system, with a corresponding logistics and sustainment tail unique to that class. Submarines and their internal systems are commonly state-of-the-practice at launch, but most navies find it necessary to upgrade the ship's combat system at least once during the operational lifetime. The evolution of threats, technology and interoperability drives the USN to upgrade their submarine combat systems and key components including the sonar (Fages 1998) (Ford and Dillard 2009) and tactical control systems continuously (Jacobus and Barrett 2002).

Over the last three decades submarine combat systems have evolved from multiple independent systems (sonar, combat control, imaging, electronic warfare, weapon control, etc.) with manual or point-to-point interfaces into networked federations of systems (FoS). Confusingly, these component systems are often referred to as subsystems in the literature.

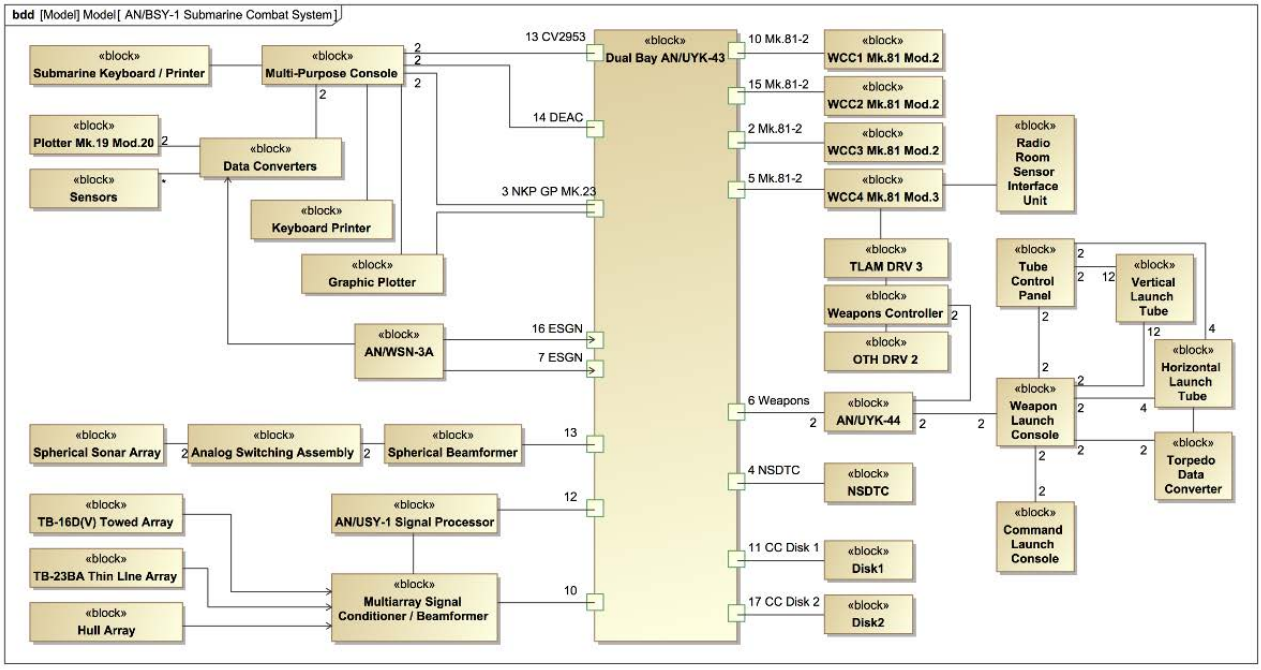

Figure 1. ***1985-era submarine combat system composed from independent component systems with point-to-point interfaces*** (SEBoK Original)

In the USN, each of these component systems has its own acquisition program, customer, and contractor team. Starting as legacy military systems hosted on traditional military-unique computational platforms, these systems have evolved to utilize Commercial Off-The-Shelf (COTS) computational and networking platforms, and leverage large amounts of COTS software.

As the component systems became more tightly interconnected, the acquisition customers established and collaboratively funded a systems engineering and integration (SE&I) program to manage the interfaces between systems, manage technology insertion and the obsolescence of common COTS components, and to integrate and test the production systems (Cooper, Sienkiewicz and Oliver 2006). Starting with the Virginia class, this SE&I program was expanded to encompass both new-production and in-service submarine modernization efforts. Over time, the combat systems of the various USN submarine classes were converged into variants of a single product line (Zingarelli, et al. 2010).

Purpose

The submarine combat system SE&I program delivers an updated production baseline annually, along with product line variants for each submarine class or subclass being built or upgraded that year. Production systems implementing this baseline are delivered to new-build submarines, and to in-service submarines being upgraded on a roughly six-year cycle. The common combat system product line is referred to as the Submarine Warfare Federated Tactical Systems (SWFTS). SWFTS is deployed by the USN on submarines of the Los Angeles (SSN 688), Ohio (SSGN 726, SSBN 730), Seawolf (SSN 21), and Virginia (SSN 774) classes, and by the Royal Australian Navy on the Collins (SSG 73) class. SWFTS is also planned for the next-generation USN Columbia (SSBN) class. Compared to the submarine combat systems that it replaced, SWFTS significantly reduces development, maintenance and training costs while delivering enhanced combat capabilities and facilitating the rapid insertion of new or improved capabilities (Zingarelli, et al. 2010).

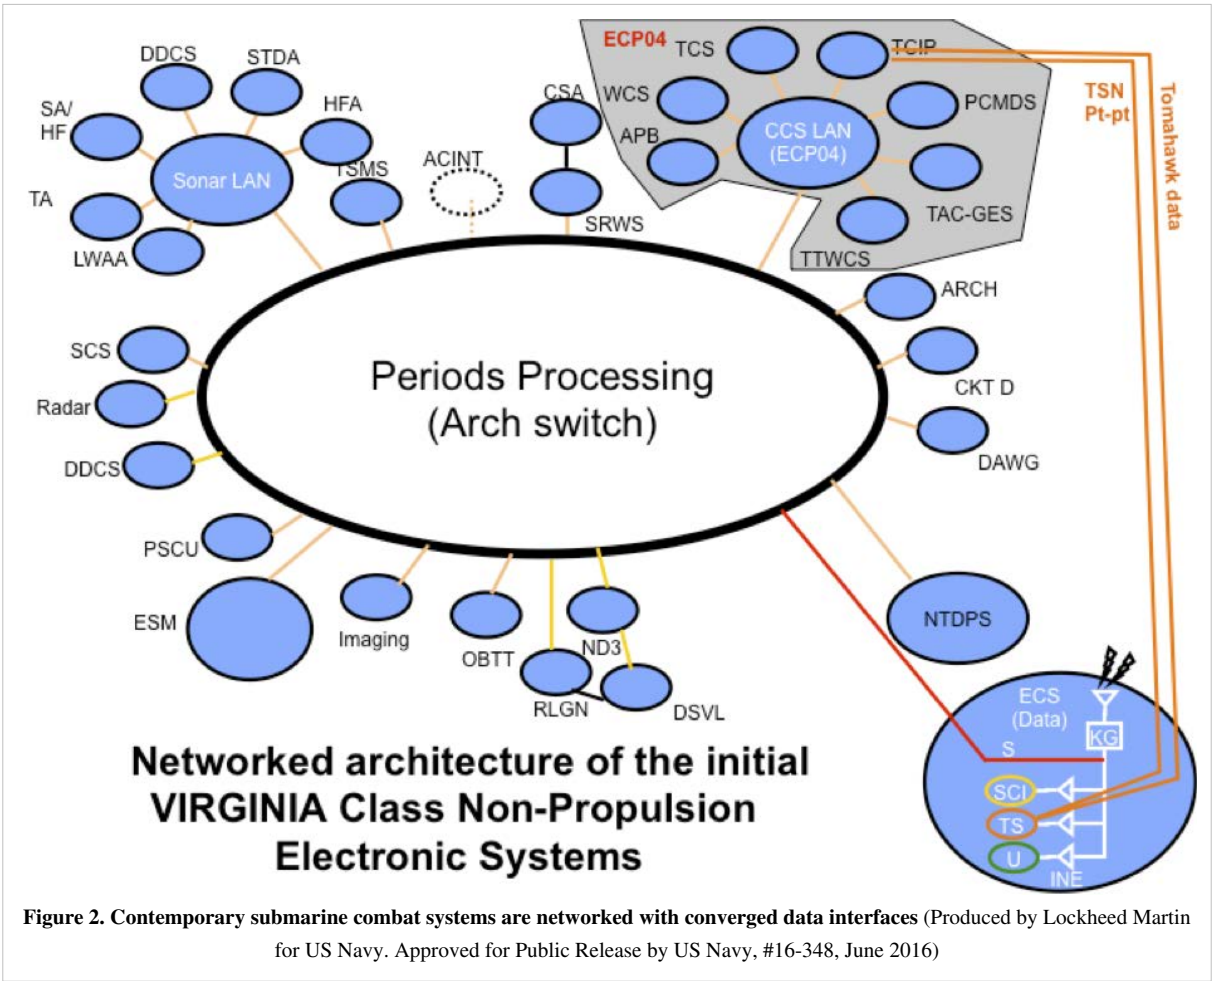

Figure 2. Contemporary submarine combat systems are networked with converged data interfaces (Produced by Lockheed Martin for US Navy. Approved for Public Release by US Navy, #16-348, June 2016)

Challenges

The USN submarine fleet encompasses substantial platform variability between class, sub-classes, and even individual ships within a sub-class. The RAN Collins class contributes additional variability. Platform variability drives combat system variability.

SWFTS is a Federation of Systems, with each platform hosting a subset of 40 systems produced by 20 different program offices. As is common with system of systems (SoS) and FoS, there is no central program office that can command the compliance of all of the component system programs. Instead, the evolution of SWFTS is executed through negotiation and consensus.

Many baselines must be produced each year: new common hardware baselines are introduced in odd years, while new common software baselines are introduced in even years (Jacobus, Yan and Barrett 2002). In addition, multiple incremental developmental baselines are established each year. Once the annual production baseline for the product line is defined, variants must be developed for each submarine class or subclass built or upgraded that year (Mitchell 2012).

Like most other defense programs, the SWFTS SE&I program is under constant pressure to accomplish more with decreasing resources. There has been steady increase in SE scope despite decreasing budgets. Program leadership has responded in part through continuous SE process improvement. Improvements have included test automation, changes in the requirements management processes and tools (spreadsheets to IBM® Rational® DOORS® to OMG® SysML®), refined tooling for change management, and the DBSE to MBSE transition that is the focus of this case study. Substantial Return on Investment (ROI) has been achieved with each major SE process or tooling improvement (Mitchell 2014, Rogers III and Mitchell 2021).

Systems Engineering Practices

During 2009 the SWFTS SE&I program conducted a Model Driven Architecture (MDA) study to determine if MDA should be the next step in the program's continuous SE process improvement. The MDA study predicted a positive ROI from converting to MBSE. In January 2010 the SWFTS SE&I program office kicked-off a three-year effort to develop and validate a SWFTS FoS model and MBSE process. In 2013 a SWFTS baseline was developed using both DBSE and MBSE in parallel. The DBSE products were used to validate the MBSE products. Based on that successful validation, the SWFTS SE&I program transitioned to MBSE for all ongoing work.

Until the transition in 2013, SWFTS SE was performed using traditional DBSE. Requirements were managed in DOORS, and reviewed and used by engineers in the form of massive spreadsheets with hundreds of columns and thousands of rows. The design of each variant was documented in Microsoft Office files. Baseline Change Requests (BCR) were documented in briefings, and analyzed by all component system programs in parallel for potential impact. Approved BCRs were manually merged into DOORS and into revised baseline documents for each effected variant.

Starting in 2010, the customer community invested in a three-year MBSE transformation effort. The engineering team performed an in-depth tool trade study to select and set up the MBSE environment. That trade study resulted in the selection of MagicDraw™ for system modeling, using Teamwork™ as the model repository.

Once the modeling environment was installed, the MBSE transformation team architected, developed and populated a SysML-based model of the SWFTS FoS interfaces. The team updated the SWFTS SE process to take advantage of the new MBSE environment, with the constraint that the MBSE process produce SE products that were effectively identical to those produced by the DBSE process.

As the SWFTS model was developed, unanticipated benefits emerged. Capturing the architecture in a model improves the depth and quality of baseline products due to the fact that, unlike the spreadsheets it replaced, the model inherently captures relationships between elements. Using the model, one can drill down and explore various aspects of the architecture, e.g., a) the network design that supports data exchanges; b) component systems that use a particular network Virtual Local Area Network (VLAN); c) service level requirements levied upon data providers.

In 2013 the new MBSE environment and process was used to produce a set of SWFTS baseline SE products. In parallel, the DBSE process produced equivalent products. The two sets of baseline products were compared in detail, with all differences traced back to root causes.

The relationships in the model also support automated integrity and consistency checking between model elements, which is also called model concordance. Analysis of these relationships identified a significant number of minor differences that were all traced to errors in the DBSE products. This validated the MBSE process, and demonstrated that while those initial MBSE baseline products were more labor-intensive than the DBSE baseline products, the new MBSE process produced higher quality products. After this validation, the SWFTS SE&I program switched over to MBSE as their basic process.

Since that transformation, SE process improvement has continued apace. Requirements management has moved from DOORS to the system model in MagicDraw. As of 2016, the system model is the baseline for requirements, architecture and the FoS design. BCR impact analysis is now performed in model, leveraging capabilities of the toolset for automated assistance. Variants are documented in the system model as system configurations. Most SE products are generated from the system model on demand.

The MBSE process has been matured and refined over subsequent baseline development efforts. As the team climbed the learning curve, the average cost of processing a BCR declined. New SE artifacts capturing specific aspects of the FoS model were conceived and auto-generated from the model to improve communication with targeted audiences. Where before the transition to MBSE it was not cost-effective to manually generate tailored SE artifacts for individual systems, developing scripts to auto-generate tailored artifacts proved cost effective and improved the efficiency of the component system developers. Additional scripts were developed to tailor the

modeling tool user interface and focus it on the specific activities performed by the SWFTS SE&I engineers. MagicDraw™ has very extensive modeling capabilities with a correspondingly expansive user interface, and tailoring the user interface both reduced the learning curve for new engineers coming onto the program and streamlined routine SWFTS SE activities.

While the initial scope of MBSE was limited to managing the interfaces between component systems, once the transition was successful MBSE started expanding out to encompass additional SWFTS SE&I tasks. MBSE is now beginning to spread into the component system programs as well as the overall submarine combat system SE&I program.

Return on Investment Achieved by Transitioning to MBSE

After the MBSE process reached a reasonable level of maturity, a retrospective analysis (Rogers III and Mitchell 2021) was performed to determine if the anticipated cost savings had been achieved. This analysis compared the requirements database-managed 2010 baselines, which were generated using the mature common requirements baseline and common change management process institutionalized by 2008, with the 2014 baselines built using the mature MBSE process. This analysis made a quantitative comparison of the efficiencies between the legacy interface requirements management process using the IBM DOORS® toolset, and the model-based interface requirements management process employing the MagicDraw™ toolset.

These two distinct SWFTS baseline updates provided a good case study as both

- utilized the same high-level SWFTS process and contract,
- involved updating the lead boat in a new group of submarines added to the SWFTS SE&I program, and
- involved updates to a similar number of submarine classes.

The second bullet is key, since it suggests that the overall level of complexity of the requirements changes is similar between the two sets of baselines.

The 2010 baseline developed using DOORS® will be referred to hereafter as the Legacy Process Baseline. The 2014 baseline developed using MBSE with the MagicDraw™ toolset will henceforth be referred to as the MBSE Baseline. The timing of these two baselines in the context of the MBSE transition is shown in Figure 3.

Figure 3. Timing of the Legacy Process Baseline and the MBSE Baseline relative to other SE process improvement. (Rogers III and Mitchell 2021)

Since a requirement modification is the basic unit of systems engineering work depicting development needs at the FoS level, it is a useful metric to compare the scope of the updates. As can be seen from Table 1, the MBSE Baseline involved 42% more interface requirements changes than the Legacy Process, while consuming only 16% more hours. Another way of looking at these numbers is that the SE hours per requirement decreased from 12.1 in the Legacy baseline to 9.9 in the MBSE baseline. This is equivalent to saying that the MBSE process is 18% more efficient than the older DBSE process. This exceeded the 13% improvement projected by the 2009 SWFTS pilot study (Mitchell 2014).

Table 1. Summary of the SWFTS MBSE ROI Analysis Baselines. (Rogers III and Mitchell 2021)

In addition to the decrease in labor hours per requirements change, measurable improvements in quality were found. A 9% reduction in total interface defects were discovered in the MBSE Baseline compared to the Legacy Process Baseline. In addition, there was an 18% shift of defect discovery from platform integration testing to laboratory integration testing with the MBSE Baseline. Estimates of the cost savings achieved by shifting defect eradication from platform integration to laboratory integration range from 1.6x (Rogers III and Mitchell 2021) to 4x (Feiler et al. 2013), but in any case these savings can contribute significantly to the overall ROI.

Lessons Learned

Seven learning principles (LPs) (Friedman and Sage 2005) were derived that address the more broadly applicable areas of systems engineering knowledge, and inform the areas of the SEBoK that are most strongly related to the case study. They are:

- Requirements traceability (LP1);
- Communications (LP2);
- Productivity (LP3);
- Quality (LP4);
- Managing Change (LP5);
- Managing variants (LP6); and
- Life cycle (LP7).

Requirements traceability LP1: MBSE improves traceability in multiple dimensions, but maintaining requirements traceability between a traditional database and the MBSE system model can be challenging. While DOORS, MagicDraw and Teamwork can interoperate to provide requirements management and traceability, the combination is fragile. Without careful configuration management, synchronization can lead to database corruption. If DOORS and Teamwork are on separate servers, maintaining the connection can run afoul of ever-evolving corporate information assurance policies.

Requirements can be managed using the SysML language inside the system model quite effectively. This approach can reduce the resources needed to keep the system model in sync with a traditional requirements database system and increase overall SE productivity.

Communications LP2: Tailored SE products generated from the system model can substantially enhance communications both within the technical team and between customer stakeholders.

Graphical depictions of the system model often communicate better to human stakeholders than massive spreadsheets and textual documents. Further, the enhanced precision driven by modeling can reduce miscommunications between both technical and programmatic stakeholders.

Having the architecture and design in a system model makes it affordable to generate specialized SE products on demand for particular communications needs while keeping all SE products in concordance. Even technical stakeholders who thought they understood the design can find new insights by looking at it in different representations.

Productivity LP3: MBSE increases productivity by enhancing communications within the team, automating routine tasks and through cost avoidance.

DBSE processes often require substantial revision to achieve the potential productivity gains of MBSE. In particular, review processes should be modified to take advantage of the tooling.

The modeling tools selected constrain how you can practically re-engineer SE processes. Automation can replace a great deal of routine SE work (document generation, identifying potential impacts of changes, etc.).

Developing strong modeling style guidelines and specialized representations, along with training materials to indoctrinate new team members as they join the program, is worth the investment. MBSE does require a trained cadre of modelers, but not all systems engineers have to become skilled modelers.

To effectively quantify the benefits of MBSE, a program needs to plan metrics collection carefully, and then stick to the plan long enough to collect meaningful data.

Quality LP4: Much of the ROI from the MBSE transition can be in improved quality. Improving the quality of SE products enhances early discovery of defects, which reduces integration costs. It also reduces latent defects in systems delivered to the customer, reducing maintenance costs and increasing customer satisfaction.

Models are less tolerant of imprecision than documents. The increased precision improves SE product quality, both in reduced defect generation and in reduced defect escape.

The automation of product generation can make specialized SE products affordable, further enhancing system quality.

Managing change LP5: How a proposed system change is understood and executed is fundamentally different between a model- and a document-centric approach. In the document-centric approach, the focus is on "What should my final output look like?" In the model-based approach, the focus is on "What does this change mean to the system? Which other parts of the system are impacted by this change?"

Change management is hard. When moving from DBSE to MBSE you need to think carefully up front about what approach you are going to take, and then design the system model to facilitate that approach. Change management also impacts tool selection, since different tools align better with different approaches.

Managing variants LP6: The most common process for managing variants in DBSE is 'clone and own', where each new product family member takes the then-current baseline and 'forks' the baseline for evolution of the variant. This makes synchronizing changes to the core baseline across the product family a very labor-intensive process. Treating variants as deviations from a core baseline in a model greatly reduces the cost of managing variation in a product family.

Variant management is hard. You need to think about what approach you plan to take up front and design your system model to accommodate it. The selected approach impacts tool selection and tailoring.

Design the system model to treat variants as deviations from the core baseline. Then changes to the core baseline are automatically shared among all variants, and impact to product family members is limited to any impact of core baseline change on specific variant deviations. This also facilitates commonality between variants, a key customer goal as commonality reduces logistics and training costs.

Life cycle LP7: MBSE can be applied early or late in the product family life cycle. While most projects using MBSE start off model-based, a program can transition to MBSE late in the life cycle.

Getting from DBSE to MBSE requires serious engineering, careful thought, planning and implementation. The SWFTS MBSE transition required three years of investment by the customer. That time and budget was spent primarily in designing and developing the system model and in re-engineering the SE processes.

Start the transition with carefully defined scope. Once that is accomplished you can expand the scope of MBSE from there.

Note

Virginia Class Submarine

- Lead Authors:
- Heidi Davidz and Alice Squires

-

This example was developed as a SE example directly for the SEBoK. It describes the Virginia Class submarine sonar system project. In particular, it highlights the approach taken to the development of a sonar system architecture and how this helped in the integration of commercial off the shelf products.

Description

Prior to the Virginia class submarine, sonar systems were comprised of proprietary components and interfaces. However, in the mid-1990s, the United States government transitioned to the use of commercially developed products - or commercial off the shelf (COTS) products - as a cost-saving measure to reduce the escalating costs associated with proprietary-based research and development. The Virginia class submarine system design represented a transition to COTS-based parts and initiated a global change in architectural approaches adopted by the sonar community. The lead ship of the program, Virginia, reduced the number of historically procured parts for nuclear submarines by 60% with the use of standardization. The Virginia class submarine sonar system architecture has improved modularity, commonality, standardization, and reliability, maintainability and testability (RMT) over historical sonar systems.

Architectural Approach: Standardization

Based on the new architectural approach and the success of the transition, system architecture experts developed an initial set of architecture evaluation metrics:

- Commonality
  - Physical commonality (within the system)
    - Hardware (HW) commonality (e.g., the number of unique line replaceable units, fasteners, cables, and unique standards implemented)
    - Software (SW) commonality (e.g., the number of unique SW packages implemented, languages, compilers, average SW instantiations, and unique standards implemented)
  - Physical familiarity (with other systems)
    - Percentage of vendors and subcontractors known
    - Percentage of HW and SW technology known
  - Operational commonality
    - Percentage of operational functions which are automated
    - Number of unique skill codes required
    - Estimated operational training time (e.g., initial and refresh from previous system)
    - Estimated maintenance training time (e.g., initial and refresh from previous system)
- Modularity
  - Physical modularity (e.g., ease of system element or operating system upgrade)
  - Functional modularity (e.g., ease of adding new functionality or upgrading existing functionality)
  - Orthogonality
    - Level to which functional requirements are fragmented across multiple processing elements and interfaces
    - Level to which throughput requirements span across interfaces
    - Level to which common specifications are identified

    - Abstraction (i.e., the level to which the system architecture provides an option for information hiding)
    - Interfaces
        - Number of unique interfaces per system element
        - Number of different networking protocols
        - Explicit versus implicit interfaces
        - Level to which the architecture includes implicit interfaces
        - Number of cables in the system
- Standards-based openness
    - Interface standards
        - Ratio of the number of interface standards to the number of interfaces
        - Number of vendors for products based on standards
        - Number of business domains that apply/use the standard (e.g., aerospace, medical, and telecommunications)
        - Standard maturity
    - Hardware standards
        - Ratio of the number of form factors to the number of line replaceable units (LRUs)
        - Number of vendors for products based on standards
        - Standard maturity
    - Software standards
        - Number of proprietary and unique operating systems
        - Number of non-standard databases
        - Number of proprietary middle-ware
        - Number of non-standard languages
    - Consistency orientation
        - Common guidelines for implementing diagnostics and performance monitor/fault location (PM/FL)
        - Common guidelines for implementing human-machine interface (HMI)
- Reliability, maintainability, and testability
    - Reliability (fault tolerance)
    - Critical points of fragility (e.g., system loading comprised of percent of processor, memory, and network loading)
    - Maintainability (e.g., expected mean time to repair (MTTR), maximum fault group size, whether the system can be operational during maintenance)
    - Accessibility (e.g., space restrictions, special tool requirements, special skill requirements)
    - Testability
        - Number of LRUs covered by built-in tests (BIT) (BIT coverage)
        - Reproducibility of errors
        - Logging/recording capability
        - Whether the system state at time of system failure can be recreated
        - Online testing (e.g., whether the system is operational during external testing and the ease of access to external test points)
        - Automated input/stimulation insertion

Other Points

The Virginia class submarine acquisition exhibited other best practices. These are discussed by Schank (2011), GAO (2008), and General Dynamics (2002).

These best practices included stringent design trades to keep costs under control, careful consideration of technical maturity of components, and the importance of program stability.

Summary

In summary, the work on the Virginia class submarine prompted a change in the traditional architectural approach used in the sonar community to design submarine sonar and validated the cost savings in both research and development (R&D) and in component costs when transitioning from proprietary interfaces to industry standard interfaces. The identification of a list of feasible architecture evaluation metrics was an added benefit of the effort.

Information System Examples

Complex Adaptive Taxi Service Scheduler

- Lead Author:
- Rick Adcock

-

This article is based around a **London Taxi Service Case Study** (Rzevski and Skobelev, 2014). The case study focuses on the development of a Real-Time Complex Adaptive Scheduler for a London Taxi Service capable of managing the complexity of many hundreds of taxi journeys in an unpredictable and changing environment, while fitting into the goals and values of the Enterprise.

Background

When this project was initiated, the company, the largest and the best-known minicab (taxi) operator in London had a fleet of more than 2,000 vehicles, each with a Global Positioning System (GPS) navigation system. The fleet comprised a variety of vehicles, including minivans and Sport Utility Vehicles (SUVs), some with equipment to match special customer requirements. Under usual circumstances, approximately 700 drivers worked concurrently, competing with each other for customers.

The company had a modern Enterprise Resource Planning (ERP) system and a call center with over 100 operators receiving orders concurrently. Some orders were received through the company website. A large team of skilled dispatchers allocated vehicles to customers.

Main characteristics of the taxi service were as follows:

- More than 13,000 orders per day
- Occasionally more than 1,500 orders per hour (1 order every 2.4 seconds)
- Unpredictable order arrival times and locations
- Various clients, e.g., personal, corporate, Very Important Persons (VIPs), a variety of discounted tariffs, special requirements suitable for the disabled, small children (child seats), transportation of pets, etc.
- Many freelance drivers who leased cars from the company and were allowed to start and finish their shifts at times that suited them, which may have differed from day to day
- Clients in central London were guaranteed pick up times within 15 minutes of order placement
- Fundamentally, the company tried to find the best economic match of vehicle to every client. However, dynamic exceptions to this basic requirement included:
  - Matching drivers going to and from home with passengers travelling in the same direction (to reduce drivers' idle runs); and
  - Giving priority to drivers with less work during a particular day (to increase drivers' satisfaction with working conditions)

No pre-planned taxi schedule was viable because any of the following unpredictable "Disruptive Events" occurred every 2 to 10 seconds:

- Order arrival, change, or cancellation
- Changes in driver profile, status, or location
- Client no-show
- Vehicle failure

- Delays due to traffic congestion, or queues at airports, railway stations, etc.

Purpose

Rescheduling up to 700 independent entities travelling in London under unpredictable conditions that change every few seconds represented an exceedingly complex task, which was not feasible to accomplish using any known mathematical method.

Manual scheduling, as practiced, could not handle the frequent disruptive events. Many perturbations, such as unexpected delays, had to be ignored by the human dispatchers.

Therefore, the project's objective was to provide effective, real-time, automated assistance to accommodate the disruptions that drove the scheduling. Thus, the project purpose became the development of a complex adaptive software system capable of managing the taxi operation complexity described above with the aim of substantially improving: (1) operational profitability; (2) customer service quality; and (3) driver working conditions.

The planned transformation was from a manual to semi-automated managed taxi operation that facilitated optional human dispatcher interactions with a complex adaptive system scheduler. A thorough analysis of contemporary practices showed that such a transformation has never been achieved before. To the best of the project team's knowledge, there were no real-time schedulers of taxi operations in existence anywhere in the world.

Challenges

The team undertaking the development of a new real-time scheduler for this client had vast experience of designing and implementing complex adaptive software, and therefore no particular challenges were anticipated. The multi-agent technology, which underpinned the system, was well understood by the team, and a methodology for managing complexity (Rzevski and Skobelev, 2014) of the task was in place.

Systems Engineering Practices

Overview

The complexity of the taxi service ruled out all conventional systems engineering practices. The real-time adaptive scheduler for the client's taxi service was developed using multi-agent software technology. STOPPED HERE The scheduler design consisted of the following major components (Rzevski and Skobelev, 2014):

1. A Knowledge Base containing domain-useful information relevant to the client's taxi service
2. A Multi-agent Virtual World which models the Real World of the taxi service and is capable of managing its complexity
3. Communication channels between the Virtual and Real Worlds which enable the Virtual World management of the Real World with or without human intervention.

The system was designed to behave as follows. In reaction to every disruptive event, Order Agents, assigned to every received order, and Driver Agents, assigned to every working driver, negotiate the most suitable Order-Driver match through the exchange of messages. Before starting negotiations, these software agents consult the Knowledge Base for the current negotiation rules. Once the best possible match (under prevailing circumstances) is agreed upon, the result is communicated to Drivers, who are free to accept or reject the task (Glaschenko et al. 2009). This process is depicted simply in the figure below.

After a successful prototype implementation, a basic version of the complex adaptive scheduler was developed as described below.

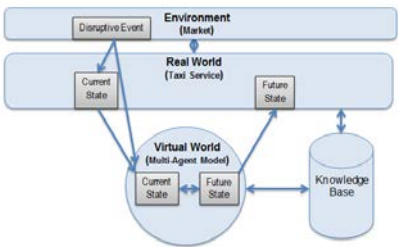

Figure 1. Essence of the event driven, real-time, adaptive scheduling of a taxi service.

Knowledge Base

The Knowledge Base consisted of: (1) Ontology, containing conceptual knowledge as a semantic network; and (2) Values, in standard databases.

The basic Ontology contained two Object Classes: Order and Driver. Order attributes were:

- Location of pick-up and drop-off
- Pick-up(urgent or booked in advance for a certain date and time)
- Type of service (standard car, minivan, VIP, etc.)
- Importance of service (a number from 0 to 100 depending upon the client)
- Special requirements (pet, child chair, etc.)

Driver attributes were:

- Type of vehicle
- Capability to complete special jobs
- Driver experience (novice or experienced)
- Domicile of driver
- Current vehicle location (GPS coordinates)
- Driver status (unavailable, break, working, free, will be free in 5/10 minutes, home transit)

Factual data on Object Instances (Individual Orders and Drivers/Vehicles statuses) were stored in client's databases, including Scenes (i.e., instantaneous models of the taxi service yielding every vehicle location and driver availability).

Virtual World

In the basic version of the scheduler, the allocation of taxis to customers was done by the negotiation between Order Agents, assigned to customers, and Driver Agents, assigned to taxi drivers. Order Agents were active: they compiled lists of available vehicles and initiated negotiations with Driver Agents. In this first version of the system, Driver Agents were designed to be only reactive: they only replied to requests from Order Agents and implemented the option selected by an Order Agent.

In the extended version, hereafter described, Order Agents and Driver Agents competed with each other or co-operated, depending on what was best for the whole enterprise. In addition to Order and Driver Agents, this version used some new types of agents, namely: External Events Agents, Regional Loading Agents, and Orders Allocation Agents.

Agents were designed to use flexible decision-making criteria instead of direct priorities, which is valuable when there is a need to deal with different categories of clients. For example, if a VIP order arrived and there was only one

driver that fully corresponded to the specified requirements and if that driver was already assigned to another job, the system would nevertheless allocate the VIP order to this driver and initiate re-scheduling of the previously agreed matches, if required.

The system first attempted to maximize company profit. Then, other criteria that are important for the business were considered, such as the service level and driver working conditions. For example, when choosing from two approximately equal options the system allocated the order to the driver who had not received orders for a longer time, thus ensuring relatively fair distribution of orders.

This virtual agent-based scheduling system was designed to work effectively with human dispatchers. In a situation where one dispatcher takes a new order and schedules a vehicle to come from north to south to pick up a client, and another dispatcher independently schedules another vehicle to go from south to north for another order, the virtual agents can spot this schedule anomaly and recommend dispatchers change their decisions to be more effective.

To enable improved performance, the taxi allocation system functioned in short cycles rather than as an immediate reaction to every event. Between the cycles, the system collected the events and placed them in a queue. During each cycle, the events from the queue were processed one by one and appropriate agents, in turn, were given control by a designated human system dispatcher. Each event thus initiated a chain of negotiations among virtual agents. When all events were processed and the system dispatcher was satisfied that the best possible schedule was produced for that cycle, the schedule perturbation was implemented in the real world, and the system fell asleep (was idled) until a new event arrived causing the initiation of the next cycle.

To decrease the dimensions of the decision space, a pre-matching mechanism was used, which determined the suitability of Order-Driver matching. This mechanism cuts off unpromising options.

The Order-Driver pairs were evaluated before the final decision was made. An evaluation mark was given to each option and good options were remembered so that the evaluations did not need to be repeated later. The evaluation mark was determined using a multi-criteria model and calculated as a sum of all criteria values multiplied by their (variable) weights.

The following criteria were used for option evaluation: distance to the order, predicted delay of the pick-up, if any, preferences of the driver, driver experience, distance of the driver to overloaded area (to utilize drivers from outlying districts), service level conformity, importance and priority of the order, driver's place in a queue (if he is waiting at an airport), driver's home address (if he is looking for an order to or from home).

Scheduling workflow included the following steps:

1. New order arrives and joins the event queue
2. Possibility of order scheduling is checked
3. A software agent is assigned to the order
4. All drivers that can complete this order are included in pre-matching
5. Evaluation of all Order-Driver pairs is done according to agreed criteria
6. The Order Agent requests order completion costs from selected Driver Agents. This cost includes the cost of transferring the order from the previously allocated driver, if any
7. The Driver Agent receives the information on the reallocation costs by sending a request to its current Order Agent
8. If the revised decision is better than the previous one, it is applied
9. Step 6 continues for all candidate drivers, for whom the initial evaluation (without transfers) was better than the current evaluation
10. If no further changes occur during the cycle, the event processing is considered finished

In order to achieve the best possible solution, the system continued to search for improvements in previously agreed Order-Driver matches until the last moment when it had to issue the instruction to a driver to fulfil an order (commitment time). During this time interval, the Driver was considered to be available for new allocations but only

if the new allocation improved specified performance indicators.

When required, Driver Agents attempted “to come to an agreement” with each other about proposed re-allocation of orders. Occasionally, compensation was offered to the Driver Agent who lost a good client in order to improve overall value of the business, and Driver Agent satisfaction, in particular. Very often the re-scheduling of allocated resources caused a wave of negotiations aimed at the resolution of conflicts between new and old orders. The length of the re-scheduling chain was limited only by the time required for a taxi to reach a customer in a busy city such as London, which normally was sufficient for several changes of the schedule.

To summarize, the system built a schedule and perpetually reviewed it, attempting to improve key performance indicators as long as the time for essential re-scheduling was still available.

The Commitment Time was dynamically calculated for each order, taking into account the priority and service type of the order and some other parameters. The introduction of the dynamic Commitment Time resulted in the increase of the fleet effectiveness by reducing the average task completion time per driver.

An option was introduced for the system to distribute the fleet according to the order-flow forecasts. Having information about the current order-flow and distribution of orders in the past, the expected order-flow was extrapolated, enabling the system to generate short-term (30 minutes) forecasts, which were normally reasonably correct. Based on the forecast, the system sent text messages to unoccupied drivers with recommendations to stay in, or move to, the region where an increased order flow was expected. This feature enabled an improved distribution of the fleet, reducing response times and idle miles and increasing the number of pick-ups.

In cases when forecasts envisaged a probability of a VIP order arrival at a significant distance from the point where drivers were advised to congregate, the system would recommend that a proximate driver to move closer to the likely order point, offering him/her a guaranteed next order in exchange for compliance. This was an important feature because there were usually enough proximate drivers to complete available orders in areas that were not overloaded, and productivity of work in overloaded areas determined the actual fleet effectiveness. The system was also designed with an option to temporarily amend criteria for the allocation of orders to drivers (for example, to extend the area where drivers are allowed to search for orders) to enable drivers to reach critical locations without being intercepted by less important orders from nearby locations.

The forecasting functionality was supported by an agent-based dynamic data mining system, which was, in fact, another complex adaptive system cooperating with the complex adaptive scheduler.

In later versions the system was designed to detect and identify drivers that cheat, i.e., deliberately providing the scheduler with false information to gain personal advantages. Recorded cases include attempts to:

- Reduce their ultimate waiting time by reporting that they were already waiting in an airport queue when, in reality, they may still have been tens of miles from the airport
- Get an earlier next order by indicating “free in 10 minutes” at or near the beginning of a long assignment
- Receive orders in their home direction by indicating “going home” several times during a day.

To reduce cheating, Driver Agents were designed to monitor drivers’ schedules and ignore their messages, when judged inappropriate.

The final version of the complex adaptive taxi service scheduler negotiated only with agents that were affected by a disruptive event and then modified only affected parts of the schedule. This capability was a key feature that improved overall effectiveness.

Connecting Virtual and Real Worlds

The Virtual World, which is a model of reality and resides in the scheduler, is connected with the Real World of customers, dispatchers, and drivers, as follows.

As customers ring the call center or visit the website to place, modify or cancel an order, dispatchers enter the pertinent information into the system. Drivers communicate with the system using GPS, mobile phones, or specialized handheld devices, conveying information on their location, direction of travel, availability, etc., and, in turn, receive instructions to pick up customers.

Lessons Learned

The system began its operation and maintenance phase in March 2008, only 6 months from the beginning of the project.

Results were extremely good: 98.5 % of all orders were allocated automatically without dispatcher's assistance; the number of lost orders was reduced by up to 2 %; the number of vehicles idle runs was reduced by 22.5 %. Each vehicle was able to complete two additional orders per week spending the same time and consuming the same amount of fuel, which increased the yield of each vehicle by 5 – 7 %.

Time required to repay investments was 2 months from the beginning of the operation and maintenance phase. During the first month of operation the fleet utilization effectiveness was increased by 5 – 7 %, which represents potential additional revenue of up to 5 million dollars per year. Such realized additional income has benefited both the company and the taxi drivers. According to available statistics, driver wages have increased by 9 % since 2008, and there is a possibility for an overall fleet growth.

Delayed pick-ups were reduced by a factor of 3, which considerably improved customer service. Urgent order average response time (from booking until taxi pick-up arrival) decreased to 9 minutes, which is the best time among all taxi services in London. For high priority orders, the response time is 5 – 7 minutes or less. Response time reductions are especially noticeable in overloaded areas.

Implementation of "on the way home" orders, an improved allocation mechanism, when compared with a previous system, gives 3 – 4 thousand miles reduction in daily fleet run, greatly benefiting both drivers and the city's ecology.

Further developments targeting business effectiveness improvements may include an analysis of vehicle movements to determine actual vehicle velocities that could improve courier service by increasing the number of orders per courier.

Successful Business Transformation within a Russian Information Technology Company

- Lead Author:
- Brian White

-

This article describes a successful business transformation of an information technology enterprise. The topic may be of particular interest, especially because this transformation was accomplished by a Russian company during the republic's fast-growing economic recovery.

For addition information, refer to the closely related topics of Enabling Businesses and Enterprises and Enterprise Systems Engineering.

Background

In 2001, the top management of the IBS company [1] in Moscow initiated a fundamental transformation to change the company's strategy and business model. The company was one of the biggest Russian information technology (IT) systems integrators at that time, with about 900 employees. Annual revenues of about $80M were mainly generated by information technology (IT) infrastructure projects (complex computing systems, multi-service networks, etc.) and hardware and software distribution. The transformation of the company to form new capabilities in IT services and the associated consulting area is the main topic in the case study.

During the transformation period (from 2001 to the present) IBS was represented as a set of autonomous business units (BUs), called constituent systems, which are virtual, independent businesses with the following characteristics:

- Profit and loss reporting was required for each BU according to management accounting procedures
- BU management established and independently conducted human resources, technology, and product policy
- A centralized back-office was organized to provide supporting functions for each BU. Thus, BUs do not have back-offices; they rely on and "pay" a corporate governing center (CGC) for these services.

A thorough enterprise system (ES) transformation was executed as a set of activities: mission analysis and capabilities decomposition, business architecting, planning of the project program, and implementation of the new business model.

Before and after transformation IBS was an exemplar directed system of systems (sos): the constituent BUs are autonomous but their operations are supervised by CGC. At the same time IBS also has significant features of an acknowledged SoS: the constituent BUs retain their independent development and sustainment approaches, and changes in the company are based on collaboration between the CGC and each constituent; even operations of BUs are not controlled but only supervised/governed by the CGC through "soft" recommendations and coordination.

IBS was a quite mature ES before the transformation, and it was thoroughly upgraded to form new capabilities of the whole system as well as of the constituents.

Purpose

In 2000-2001 IBS management forecasted considerable growth of the Russian IT services and consulting market based on the fast growing Russian economy, which was rapidly recovering from the national financial crisis of 1998. The largest corporations started overseas expansion and borrowed from international markets to finance this growth. IBS predicted corresponding growth in the complexity of business processes and their associated software and hardware systems, all of which should require more consulting and IT services.

Based on this forecast, management established a strategy goal to double the share of IT services and consulting from 25% to 50% over one year; further growth in this business was planned as a long-term trend.

The consulting and IT services business is very complex technologically and organizationally and dramatically differs from IBS's former infrastructure focus. Thus, a fundamental transformation was required, and it was executed during 2002.

Initially detected problems appeared as expenditures exceeding resources, slow delivery of the projects and reworking. Later, as it was expected, new problems appeared, for example, disinterest of BUs' managers in developing new technologies or raising qualified employees' motivation. All those problems were solved during transformation and during further development.

The first step of the transformation included strategic analysis and mission-to-capabilities decomposition. Five major capability groups to be focused on were defined. The groups and exemplar capabilities for each group are represented at Figure 1.

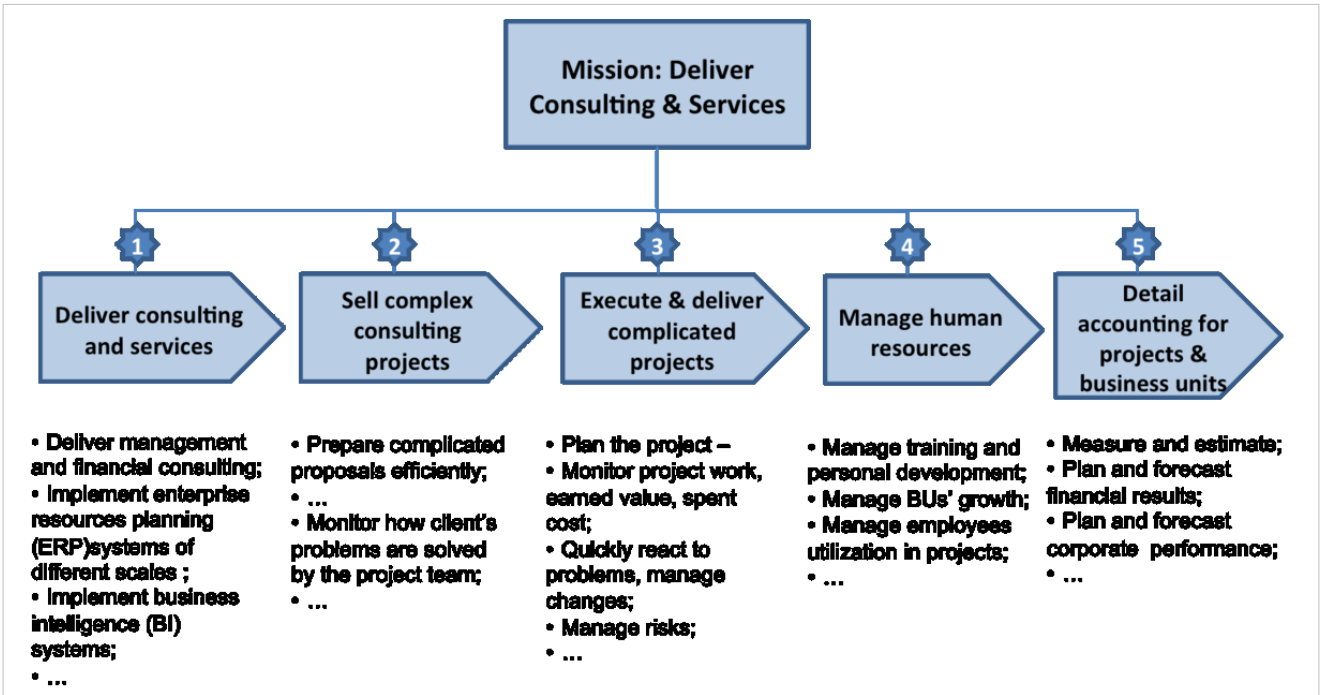

Figure 1. Mission and capabilities desired. (Belov 2014) Reprinted with permission of Taylor and Francis, New York, NY. All other rights are reserved by the copyright owner.

Challenges

All main challenges were caused by knowledge/information deficit described by three factors listed as a, b, and c below.

a. The lack of experience in enterprise transformation (and capability-based approaches, even the lack of any textbooks or guides in those areas) was the major challenge which IBS management faced. The task to be solved did not devolve to organizational changes (which was a well-developed and described area), but was appropriately allocated to enterprise system or system of systems (SoS) engineering. In spite of the lack of experience, it was decided to prepare and execute the transformation based on the company's employees without involving external consultants. The following arguments supported the decision.

- The task to be solved was not typical, so there weren't widely used and well tested algorithms or methods, and there weren't a lot of consultants experienced in exactly what was needed. So only consultants with general experience (strategy consulting, organizational management) might be hired.
- The Russian consulting industry in 2001-2002 was not well developed, so only foreign professionals were available. But foreign consultants would have needed to study Russian specifics; such study would have unduly lengthened the duration and increased the cost of the transformation.
- A joint transformation team would have to be formed, and IBS employees would have to be involved: management would have to be interviewed and be involved in decision making. In any case, all employees would have to participate in change implementations.
- External consultants are not stakeholders; so their level of interest in helping to achieve success might not be very high, and their output also might not be outstanding.
- Unwillingness to open professional secrets and other intellectual property issues to direct competitors were other factors that prevented hiring of external consultants.

Thus, the final decision was to execute the transformation without involvement of external consulting resources. A special BoU responsible for business processes development was established and an agile program management approach was applied to handle challenges and to pursue opportunities as well as to mitigate risks.

b. A very high complexity IBS as an enterprise system or SoS. Management recognized that the company and its environment was very complex, with many different agents, many constituents, and countless relationships; and that an enterprise system or SoS might become even more complex after transformation. This complexification happened as the company became an "extended enterprise," the governing hierarchies weakened, and the demand for more sophisticated relationships increased.

c. The risk of mistaken forecast of IT market development. The expected growth of the consulting and services market might have not happened. In this case the transformation would have been senseless. This challenge generated additional emotional stress for management.

Systems Engineering Practices

The SE task of the transformation was established in the form: to develop required capabilities for an enterprise system or SoS – IBS company. The SE process might be represented by the following specific IBS interpretation of the vee (v) model ("V model") with Stages 1 through 7 (Figure 2).

Initially (Stage 1) the mission was translated to capabilities (Figure 1); "understanding the constituent systems (BUs) and their relationships" was executed. The transformation team found that capabilities might not be directly translated to any business-agent. Neither BUs (they serve as resource pools), nor projects (being temporal elements), nor employees (each of them have a finite set of skills, experience, responsibilities, etc.) might realize necessary capabilities.

Realizing this (Stage 2) transformation team defined several key areas (Figure 2) of company's operations or activities which were supposed to be changed to form new capabilities. Appropriate artifacts (procedures, guides,

documents, software systems) to support new capabilities were developed and implemented for each of the areas; these new assets formed exactly the corporate infrastructure of new business model.

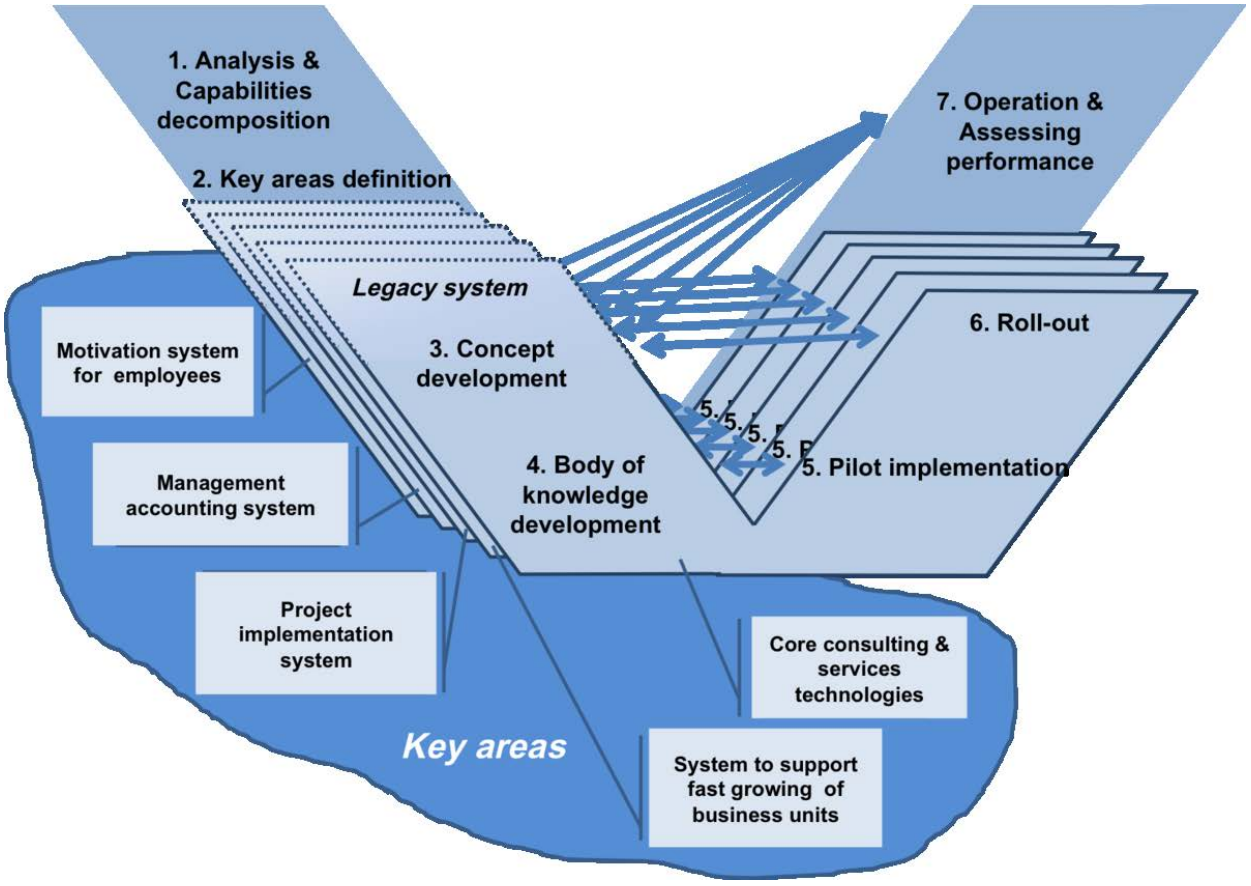

Figure 2. "V model" of the systems engineering process of the transformation. (Belov 2014) Reprinted with permission of Taylor and Francis, New York, NY. All other rights are reserved by the copyright owner..

For each new and legacy system (Stage 3), a set of conceptual design documents was developed, describing approaches, polices, processes, and procedures. The entire set of documents formed the business architecture description of the company. The description connected all key areas and defined a target operation model of the company after transformation. This architecture represented multiple views of the IBS company, and thus aptly reflected its enterprise system or SoS nature.

Somewhat in contrast with the conventional linear systems engineering approach advocated by the V model, Stages 4-6 were conducted in parallel to save time and resources. The company's performance (Stage 7) should be monitored based on indicators' measurements, and improvements should be developed and implemented (arrows from Stage 3 to Stage 7). Such iterations have been executed in practice not only during transformation but also later, when procedures, guides and the whole systems were updated.

Integration and interoperability of the new systems required a thorough integration of parallel development jobs. So joint workgroups were formed of the employees at the level of low officers; and CGC played the role of integrated workgroup at the management level. Actually, multi-level integrated workgroups were formed.

The major complexity and risks derived from the challenges described above.

The transformation team developed and used an approach which is very similar to the agile development approach to address those risks. The following principles were used to manage the portfolio of projects in case of uncertainty and deficit of knowledge.

- Form solutions as fast as possible (but not necessarily with pure quality) to test them in practice faster.
- Recognizing failures are unavoidable, perceive them readily and react rationally.

- In case of failure, analyze the situation and find a new solution, generate changes, and update the plan.
- Work in parallel, verifying and coordinating intermediate results.
- The schedule might be corrected and updated but should not be jeopardized by improper execution.
- Formulate and test the most critical and most questionable solutions at first.
- Start from pilot area and then expand to embrace the entire scope.
- Use high quality monitoring and a "manual control mode" for piloting and testing developing solutions but not additional aspects to limit waste of the resources.

Following those principles, including a very strong discipline of execution, a high level of the sponsorship and all-employee involvement enabled the transformation to be completed on time without hiring consultants while keeping and developing on-going business.

Lessons Learned

IBS's accomplishment of the mission was the major result of ES transformation. Shareholders and management recognized that new capabilities had been formed, that the company could deliver consulting and services, sell and execute complex projects, manage consulting resources effectively, measure its performance, and plan and forecast financial results. Created capabilities are emergent in some sense because they are not directly related to concrete constituents (BUs, or employee, or projects) but are realized by means of integrated end-to-end processes and functions, which are executed in the projects by employees.

The systems organization did not dramatically change during transformation; "visible structure" was not practically changed: no new types of business-agents appeared, existing types did not change much. Those factors did not create new capabilities. Target capabilities were formed as the result of development and implementation of, it would seem, auxiliary and supporting tools – new capabilities support systems. New capabilities were formed mainly by the changes in the intangible areas of governing media, corporate culture, relations, and personnel competences; as well as by the creation of new capabilities support systems; without considerable changes in main company's business-agents. (Refer to Figure 3.)

The main challenges which management faced (the lack of experience and the ambiguity of market growth forecast) made the uncertainty factor the critical one in the transformation.

What Worked and Why?

An agile program management in general demonstrated its efficiency and applicability to "soft and uncertain" tasks, especially in triggering a pre-established process for dealing with unexpected events; the main aspects of the approach are:

- Senior and credible sponsors
- Multi-level integrated project team(s)
- Open information exchange
- Partnership and collaboration
- Proactive and motivated parties and constituents
- Creative and innovative way of development

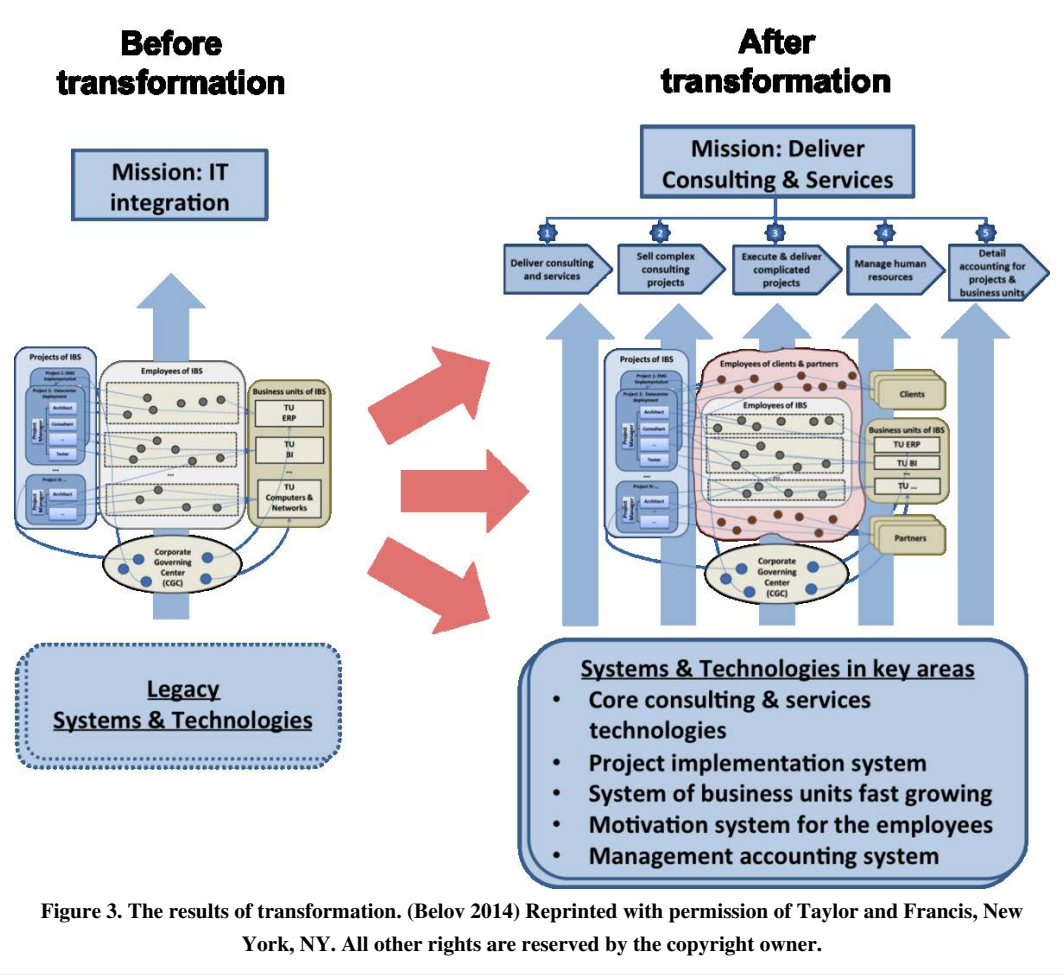

Figure 3. The results of transformation. (Belov 2014) Reprinted with permission of Taylor and Francis, New York, NY. All other rights are reserved by the copyright owner.

- Prioritizing and focusing on the most ambiguous elements of systems design
- Piloting and subsequent roll-out in realistic environments
- Strong project scope control
- Strong project execution control – time schedule and resources control.

What Did Not Work and Why?

Perhaps corporate knowledge base development was the only more or less serious task which was not solved in transformation. The company's management understood the usefulness of knowledge accumulation and further alienation from the carriers in utilizing their business knowledge, so the goal of developing their own knowledge base was established. Special database and software systems were developed with appropriate guides, reports and data collection forms; but formal regulation to fill in engineering knowledge accumulation templates did not work. However, this issue later progressed quite naturally and simply: common folders were established to store project data in free formats. Such folders served to accumulate knowledge but in flat, unstructured form.

Best Practices and Replication Prospects

The following methods and approaches were proven as efficient and convenient in transformation.

1. Capability-based development approach and capability-based architecting might be recommended to be utilized in creation and transformation of an enterprise system or SoS. These focused all efforts on the required capabilities and involved very important relations from mission to capabilities and to functions in the systems engineering process.
2. An agile program management might be used to solve a wide range of fuzzy and ambiguous problems of different scale in the areas of SE, ES engineering, and SoS engineering where there is much uncertainty and lack of expertise and proven methods or algorithms to solve them. The combination of “soft” and very creative designs with strong planning and progress control is the crucial foundation of this approach.
3. Key area definition and development appropriate to generating new capabilities for support systems (core consulting and services technologies, project implementation systems, systems for business unit growth, management accounting systems, motivation systems). Precisely defining these areas and developing integrated systems in these areas might be considered as quite common for application to a broader group of ESs.

Federal Bureau of Investigation (FBI) Virtual Case File System

- Lead Authors:
- Heidi Davidz and John Brackett

-

This case study presents systems and software engineering issues encountered in the Federal Bureau of Investigation (FBI) Virtual Case File (VCF) project in the period between 2000-2005. VCF development was abandoned in 2005 after over $170 million had been spent.

Domain Background

The FBI is an organization within the United States Department of Justice (DoJ) consisting of 23 divisions, including counterintelligence, criminal investigation, and cybercrime. The Bureau's 12,400 agents investigate everything from counter-terrorism leads to kidnappings. They interview witnesses, develop informants, conduct surveillance, hunt for clues, and collaborate with local law enforcement to find and arrest criminals. Agents document every step and methodically build case files. They spend a tremendous amount of time processing paperwork. This system of forms and approvals stretches back to the 1920s when forms for all of the bureau's investigative reports were standardized.

In 2000, the Bureau had hundreds of standardized paper forms and an obsolete information technology (IT) systems. The FBI's 13,000 computers could not run modern software. Most of the agency offices were connected to the FBI Intranet with links operating at about the speed of a 56 kilobits-per-second modem. Agents could not e-mail U.S. Attorneys, federal agencies, local law enforcement, or each other; instead, they typically sent case-related information by fax. The agency's problems in 2000 were summarized in the *9/11 Commission Report*: "The FBI's information systems were woefully inadequate. The FBI lacked the ability to know what it knew; there was no effective mechanism for capturing or sharing its institutional knowledge" (National Commission on Terrorist Acts upon the United States 2004).

In September 2000, Congress approved $380 million over three years for what was then called the FBI Information Technology Upgrade Program. Eventually divided into three parts, the program became known as the Trilogy Information Technology Modernization Program. The first part would provide all 56 FBI field offices with updated computer terminals, as well as new hardware such as scanners, printers, and servers. The second part would re-implement the FBI Intranet to provide secure local area and wide area networks, allowing agents to share information with their supervisors and each other. The third part was intended to replace the FBI's investigative software applications, including the obsolete Automated Case Support (ACS) system.

In June 2001, the FBI awarded a contract to develop the investigative software applications of Trilogy to Science Applications International Corporation (SAIC) over a three year period. The purpose of the software to be developed was to:

- provide the capability to find information in FBI databases without having prior knowledge of its location, and to search all FBI databases with a single query through the use of search engines;
- Web-enable the existing investigative applications;
- improve capabilities to share information inside and outside the FBI;
- provide access to authorized information from both internal and external databases; and
- allow the evaluation of cases and crime patterns through the use of commercial and FBI-enhanced analytical and case management tools.

After the September 11 terrorist attacks, the inability of FBI agents to share the most basic information about al Qaeda's U.S. activities was front-page news. Within days, the FBI's obsolete technology infrastructure was being

discussed in Congress and the FBI was under intense pressure to improve its information sharing capabilities. On September 4, 2001, Robert S. Mueller III became FBI director, and, in the face of intense public and congressional pressure, Mueller accelerated the Trilogy program. The planned three-year period to develop the investigative software was considered politically unacceptable. In January 2002, the FBI requested an additional $70 million to accelerate Trilogy; Congress went further, approving $78 million.

Providing web-enablement of the existing but antiquated and limited ACS system would not provide the investigative case management capabilities required to meet the FBI's post-September 11 mission. In December 2001, the FBI asked SAIC to stop building a Web-based front end for the old programs. Instead, SAIC was asked to devise a new case management system, the Virtual Case File (VCF), to replace ACS. The VCF would contain a major new application, database, and graphical user interface. In order to make both criminal and terrorist investigation information readily accessible throughout the FBI, major changes to the standardized FBI processes would be required. This case study focuses on the VCF component of the Trilogy program.

Case Study Background

The most complete description of the development of the VCF is the report by the DoJ Office of the Inspector General (OIG). The OIG reports to the Attorney General and is independent of the FBI organizations responsible for the Trilogy program. The introduction to the report states, "We conducted this audit to assess the FBI's progress in meeting cost, schedule, technical, and performance targets for the three components of Trilogy. We also examined the extent to which Trilogy will meet the FBI's current and longer-term IT needs" (OIG 2004).

An IEEE *Spectrum* article complements the OIG audit report by detailing the development of the VCF requirements, the contractor's activities, and the project management failures by both the FBI and the contractor. The contractor's viewpoint is presented in testimony given before a subcommittee of the U.S. Senate Appropriations Committee.

These materials, in total, provide a comprehensive view of the VCF program and the reasons for its failure.

Case Study Description

In the political environment following the 9/11 attacks, funding for the VCF project was never a problem. By early 2002, SAIC and the FBI committed to creating an entirely new case management system in 22 months. High-level funding enabled the project to continue gaining momentum in spite of the problems it encountered. The scheduling for the VCF project focused on what was desired, not what was possible. Trilogy's scope grew by approximately 80% from the initial project baseline (Moore 2010).

The reasons for the failure of the VCF project are associated with the non-use or misuse of numerous system engineering practices, especially within stakeholder needs definition, system requirements definition, planning, assessment and control, and risk management. Given the political pressures following the 9/11 attacks, the schedule was accelerated to the point that it was nearly impossible for the developers to follow an appropriate systems engineering process.

The FBI cycled through five people in the role of Chief Information Officer in four years and most decisions were made by committees. In order to compress the schedule, the FBI even proposed replacing the ACS with the VCF over a weekend using an IT procedure called a "flash cut-over." In this proposed implementation, the ACS system would be taken offline and entirely replaced by VCF. Once the cut-over happened, there would be no mechanism to return to ACS, even if the VCF did not work properly.

SAIC worked under a cost-plus-award-fee contract for the VCF as the scope of the project was undefined in early 2002 when work began. Given the schedule pressures, the FBI believed that there was no time to develop formal requirements (glossary), validate them with the various FBI user communities, and then estimate the cost and time required to develop the VCF. The SAIC contract did not require specific completion milestones and the cost-plus contract allowed the scope to increase. VCF was a case of not having the requirements sufficiently defined in terms

of completeness and correctness. The continuous redefinition of requirements had a cascading effect on what had already been designed and produced. Once there was demonstrable software, change requests started arriving—roughly 400 from December 2002 to December 2003.

The new FBI Intranet was specified during 2001, before the start of the VCF project and with little understanding of the network traffic that would result from information sharing. By early 2003, the FBI began to realize how taxing the network traffic would be once all 22,000 users came online. The requirements for the FBI Intranet were modified based on the best guesses for the bandwidth that would be required when the VCF was fully operational. By early 2004, the new FBI Intranet was in operation, although the VCF software was far from complete.

In reaction to the time pressure, SAIC broke its VCF development group into eight teams working in parallel on different functional elements of the program. However, this posed many integration challenges and the eight threads would later prove too difficult for SAIC to combine into a single system. By the time VCF was canceled, SAIC had developed over 700,000 lines of software based upon an incomplete set of requirements that were documented in an 800-page volume.

Summary

The OIG summarizes its conclusions as:

> *Various reasons account for the delays and associated cost increases in the Trilogy project, including:*
>
> - *poorly defined and slowly evolving design requirements,*
> - *contracting weaknesses,*
> - *IT investment management weaknesses,*
> - *lack of an Enterprise Architecture,*
> - *lack of management continuity and oversight,*
> - *unrealistic scheduling of tasks,*
> - *lack of adequate project integration, and*
> - *inadequate resolution of issues raised in our previous reports on Trilogy. . . .*
>
> *According to the Government Accountability Office (GAO), an Enterprise Architecture is a set of descriptive models such as diagrams and tables that define, in business and technology terms, how an organization operates today, how it intends to operate in the future, and how it intends to invest in technology to transition from today's operational environment to tomorrow's. . . .*
>
> *As of early 2005 the FBI's operations remain significantly hampered due to the poor functionality and lack of information-sharing capabilities of its current IT systems. . . .* (OIG 2005)

In May 2005, FBI director Mueller announced Sentinel, a four-phase, four-year project intended to fulfill the purpose of VCF and provide the Bureau with a web-based case and records management system. During the previous five years, commercial case management software had become available; as a result, Sentinel is intended to utilize commercial off-the-shelf (COTS) software. A report by the OIG in late 2009 describes Sentinel and its status at that time. Sentinel was put online for all employees on July 1, 2012, and it ended up at $451 million and 2 1/2 years overdue (Yost 2012).

Management System Examples

Project Management for a Complex Adaptive Operating System

- Lead Author:
- Rick Adcock

-

This article is based on the **Complex Adaptive Operating System: Creating Methods for Complex Project Management** case study (Findlay and Straus, 2015). The case study focuses on creating tools and methods that project managers can use in managing complex adaptive systems projects.

Background

The International Centre for Complex Project Management (ICCPM) is a non-profit organization that was created to address "the international community's ability to successfully deliver very complex projects and manage complexity across all industry and government sectors" (ICCPM, 2012).

In an ongoing effort to help member organizations successfully undertake major complex projects, ICCPM conducted a bi-annual series of international round-tables. The purpose of the round-tables was to better understand what contributes to the success of complex projects and to identify and develop new and improved tools and approaches. The round-tables were facilitated using a computer-assisted collaborative meeting process that leverages the features of complex adaptive systems—described below—to help people with diverse viewpoints and experience create new collective understanding and plans for action.

Complex major projects are known for being unsuccessful in on-time and on-budget completion. A survey (IBM, 2008) of 1,500 change managers found that only 40% of projects finished on time and on budget. Barriers to success were the inability to change attitudes or mindsets (58%), dysfunctional culture (40%), lack of senior management support (32%), and underestimating the complexity of a project (35%).

However, several new systemic approaches show considerable promise as a way to think about and manage projects. Six frameworks help inform these approaches: systems thinking, the features of complex adaptive systems (CASs), complexity theory, the Complexity Model of Change (Findlay and Straus, 2011), polarity thinking as a way of thinking about and leveraging wicked problems, cognitive complexity, and adult development theory.

Systems thinking recognizes whole systems and the interdependencies of their parts. A system may be defined as "a set of things, organisms, and people that, as a result of their interconnection, produce their own patterns of behavior over time" (Meadows, 2008, p. 2). A system cannot be understood by focusing on its parts alone (Wheatley, 1999). To successfully address and influence a system, such as a complex project, one must understand the whole and how its parts interact.

Some project managers continue to think of a project as a "machine" that operates according to linear or algorithm rules. This persistent and largely unhelpful meme is now being displaced by a new and more robust model, which regards projects as complex adaptive systems (CASs). Unlike strictly mechanical systems, CASs are self-organizing, learn from experience, are emergent, and from time to time undergo large scale phase transitions to new and higher states of the system. This view of large-scale projects—which are heavily influenced by human interaction—is proving to be much more accurate and allows project managers to leverage techniques for exerting influence in

environments that have previously presented intractable problems .

Leaders of complex projects would also be wise to consider three fundamental theorems of complexity theory, which apply to CASs and which are critical to project success. These are a robust model of the system, requisite variety and adopting solutions which act at an appropriate scale.

- The robust model axiom considers that “no one can effectively influence a system until they have a thorough understanding of its scope and the connections and interdependencies” (Conant and Ashby, 1970).
- The law of requisite variety contends that “complexity can only be dealt with by equal or greater complexity” (Ashby, 1956, p. 2). In other words, in order to deal effectively with the diversity of problems presented by a complex project, one must have a repertoire of responses which is (at least) as nuanced as the problems themselves (Requisite Variety, 2015).
- The scale condition requires that those who wish to exercise leverage over a system must recognize that “highly complex situations can best be addressed by greater degrees of freedom at the local scale so that innovation and adaptability are maximized” (Bar-Yam, 2004).

A third framework, the Complexity Model of Change, is a model of socio-technological change, comprising a series of growth and decay curves or waves, which helps project managers better understand how to influence systems and design new ones, so the roles, methods, rules of interaction or engagement, technologies, and relationships between people are better aligned with each other and the desired outcome. The overlapping waves represent large-scale eras, for example, the Industrial Age and the Information Age, which have at their core a metaphor, for example, the machine and the computer. The current wave, the Knowledge Age, is based on a network metaphor. The wave we are now entering is the Wisdom Age, which began in 2010. Its core metaphor is the complex adaptive system and the main thrust of this period is the wise application of knowledge.

Another area that project managers may now address differently is that of wicked problems or paradoxes: problems that are ill-defined and recurrent, and which, when attempts are made to solve them with single optimal solutions, create another problem. Polarity thinking regards wicked problems as sets of interdependent values or ideas—like centralizing for efficiency and decentralizing for adaptability—that persist together over time and need each other for the success of the system. If we pay attention to one pole at the expense of the other, we achieve sub-optimal results. When we manage polarities as a system, we realize the benefits of both poles and achieve high performance over time with a minimum of vacillation and the need for correction.

Other disciplines that are critical to project success are understanding and making best use of new ways of thinking about issues and relating to others in more flexible and adaptive ways. Theories of cognitive complexity and adult development theory can contribute to how we think about this problem. For example, “triple-loop learning” (Gragert, 2013), helps us think about issues from a higher level of cognitive complexity. Instead of asking “Are we doing things right (single loop)?”, we might ask, “Are we doing the right things (double loop)?” or “How do we decide what is the most effective paradigm to use to influence and create benefit for the system (triple)?”

Purpose

The purpose of the ICCPM roundtables was to help project managers develop new and better ways to lead complex major projects, by bringing together people from both the buy-side and the supply-side to share their knowledge and experience and to grow a network of practitioners, professionals, researchers, and educators able to deliver leading edge complex project management solutions to client organizations and partners around the world (Findlay and Straus, 2015, p. 489).

Challenges

There are many challenges to be addressed in the complex project management environments. The three top contenders are 1) developing new ways of thinking, acting, and interacting; 2) developing more robust models of the system by getting everyone in the room—the project management team and their stakeholders; and 3) steering projects through multiple disruptive socio-technological shifts using the feature of complex adaptive systems.

> "People, their organizations, and their projects need to be capable of reorganizing into new forms, which are a better fit with the new context" (Findlay and Straus, 2015, p. 494).

Systems Engineering Practices

One of the tools Findlay and Straus use to deal with all three challenges in the context of group interaction, such as the ICCPM round-tables, is the Zing complex adaptive meeting process. The process is used to guide conversation in the room, to capture, simultaneously display ideas and to help participants integrate and make meaning from the ideas. The tool was used for the round-tables to help people work together in new ways, develop new and better models of the system together and to design and pilot new and better decision and learning methods.

The technology "provide[s] a container for a suitably representative sample of the people in the system to meet and conceptualize a robust model of the system and develop strategies for how to leverage the system" (Findlay and Straus, 2015, p. 492).

A "talk-type-read-review" (Findlay and Straus, 2015, p. 492) etiquette was employed to organize the session, which, in complexity theory terms, is a simple rule of interaction. Rich, open-ended questions guide the conversations, the ideas are read out loud and the common themes or stand out ideas are recorded by the facilitators.

The open-ended questions are asked one at a time to explore all possibilities and reduce complexity. Although, round-table participants often held opposing views at the beginning of the session, through a processes of continual, iterative feedback, they ultimately arrived at similar or complementary conclusions by the end of the round-table.

The process "automates"—or helps participants engage in—ways of interacting that incorporate a higher level of cognitive complexity than the participants might engage in individually, thus facilitating a shift in the group to a higher level of system performance.

Lessons Learned

The role of leaders of complex projects is to help their organization systems successfully deliver on time and on budget amidst constant change. Their mandate is to deliver amazing new solutions while making few or no mistakes—a challenging goal even in far less complex environments. In order to be successful, project leaders (and their teams) need new systems structures—new tools and methods—that reliably get better results. They need to have a robust and fresh understanding of the systems over which they preside and how they might influence them to greatest effect.

No longer can the complex project leader go off into a corner and design a project and then try to sell it to the community and political leaders, for example. Leaders now need to involve the whole system in the design of a project from its inception through to completion. They need to deal with wicked problems not by looking for the one best solution, but by integrating and leveraging competing ideas. This requires a shift in perspective: from attempting to "control" a complex project system as one might control a mechanical device, to understanding projects as highly complex and interconnected "living" systems that evolve over time. While we do not have "control" over our systems in the classical sense, we can exert influence very effectively, provided that we constantly update our understanding of what is going on and learn new ways to act and interact that are more likely to achieve our desired outcomes.

To achieve this, leaders need to develop the capacity to "anticipate the skills, leadership and coordination roles, technologies, methods, and processes that will be required to successfully surf the waves of change…" (Findlay and Straus, 2015, p. 501).

The 2012 ICCPM round-table series discussion paper (ICCPM, 2012) uses the example of a system undergoing transformation of many levels to illustrate the difficulty that complex project leaders face:

> "The issue has been characterized as learning to fly a plane, while the plane is already in the air, and being re-assembled into another kind of transportation technology altogether. And, at the same time, the current passengers are disembarking and another group is boarding that demands a better quality of service or experience at lower cost than ever before. (ICCPM 2015 p. 21)"

This case study illustrates the need, in times of accelerating change, of "a real-time, systems-wide approach to the development of the methods and tools for managing complex projects" (Findlay and Straus, 2015, p. 500) so leaders can deal successfully and creatively with uncertainty and ambiguity.

Medical System Examples

Next Generation Medical Infusion Pump

- Lead Author:
- Heidi Davidz

-

This case study summarizes the systems engineering aspects of the next-generation Symbiq™ IV (intravenous) medical pump development. Symbiq™ was developed by Hospira Inc. and documented in detail in Chapter 5 of the National Research Council book, *Human-System Integration in the System Development Process.* As described in the book, Symbiq™'s purpose was "to deliver liquid medications, nutrients, blood and other solutions at programmed flow rates, volumes and time intervals via intravenous and other routes to a patient, primarily for hospital use with secondary limited feature use by patients at home" (Pew 2007).

Domain Background

This case study provides insight into the use of systems engineering practices in a medical application.

Case Study Background

The project that is the subject of this report was approved by the Governing Board of the National Research Council, whose members are drawn from the councils of the National Academy of Sciences, the National Academy of Engineering, and the Institute of Medicine.

The study was supported by Award Nos. W911NF-05-0150 and FA5650-06-1-6610 between the National Academy of Sciences, the U.S. Department of the Army, and the U.S. Department of the Air Force.

Case Study Description

In creating a next-generation product, Hospira proposed to introduce new IV pump features, such as:

- multi-channel vs. single-channel liquid delivery;
- the ability to group multi-channeled devices together;
- associated user-programming capabilities and programmable drug libraries for specifying parallel delivery of liquids;
- use of color touchscreen devices;
- integration with numerous types of hospital information systems;
- ease of use for both medical personnel and patients at home;
- handling of potential hardware, software, and human-user faults;
- compliance with U.S. and international safety standards;
- use of alternating-current or battery power; and
- the ability to be cost-competitive and attractive to traditional medical and hospital administration personnel.

Many of these features are highly coupled, such as the multi-channel hardware controls, concurrent software synchronization, distinctive displays and alarms for multi-channel devices, and rigorous medical safety standards.

Views of the resulting medical infusion pump can be found as Figures 5-5 and 5-6 in Chapter 5, page 107 of the Pew and Mavor (2007) book. Systems engineering for the device involved a great deal of concurrent analysis and

engineering of its hardware, software, human factors, operational, business, and safety aspects. It has been a commercial success and won the 2006 Human Factors and Ergonomics Society's User-Centered Product Design Award and the 2007 Medical Design Excellence Award.

Not only were there numerous technical challenges in the development of Symbiq™, but there were also challenges in the systems engineering of a product with a life-cycle operational concept that would produce satisfactory outcomes for a wide variety of product and operational stakeholders whose value propositions were often in some conflict. Some stakeholders wanted numerous features that would require a complex user interface, while others wanted a simple and easy to learn interface. Some users wanted the most advanced color touchscreen displays available, while others wanted a simpler, less-expensive product that was harder to misuse due to inadvertent screen commands. Some organizations felt that a minimal interpretation of the required safety features would be acceptable, while others advocated ultrahigh assurance levels. Some marketing personnel wanted a quick development and fielding of the basic product to capture market share, while maintainers wanted initial built-in life cycle support, maintenance, and diagnostic capabilities.

In such situations, many organizations focus on making quick requirement decisions and rapidly proceed into development. However, Hospira's understanding of the uncertainties and risks caused them to pursue a risk-driven, incremental commitment course of buying information to reduce risk, as emphasized in the SEBoK Part 3 knowledge area on Risk Management. As described in Pew and Mavor (2007), Hospira used a version of the Incremental Commitment Spiral Model (ICSM) summarized in the SEBoK Part 3 Knowledge Area on representative systems engineering process models. The following sections describe the project's incremental system definition progress through the ICSM exploration, valuation, foundations, and Development phases. Some evolution of terminology has occurred, the Pew and Mavor (2007) version uses ICM instead of ICSM and "architecting phase" instead of "foundations phase".

Symbiq™ Exploration Phase Summary

In the exploration phase, the project carried out numerous analyses on stakeholder needs, technical opportunities, and business competition. Using these analyses, the project team determined ranges of preferred options. Stakeholder needs analyses included contextual inquiry via shadowing of nurses using IV pumps and followup interviews, as well as creating task flow diagrams, use environment analyses, and user profiles analyses. Technical opportunity analyses included initial conceptual designs of multi-channel pump configurations, evaluation of commercially available single-color and multicolor display devices with touchscreen capabilities, and software approaches for specifying multi-channel delivery options and synchronizing concurrent processes.

Business competition analyses included hiring a management and marketing planning firm to examin next-generation pump competitor strengths and weaknesses with respect to such capabilities as the number of pump channels, therapies, programming options, air-in-line management, battery and alternating current capabilities, biomedical domain expertise, and alarms. Several key competitive advantages of a next-generation pump were identified, such as the ability to read bar-codes, small size, light weight, stand-alone functional channels, an extensive drug library, a high level of reliability, and clear mapping of screen displays and pumping channels.

Market research and market segment analyses also identified market windows, pricing alternatives, hospital purchasing decision-making trends, and safety aspects. These were iterated by focus groups of key thought leaders in critical care. The results were factored into a product concept plan, cost analysis, and business case analysis. These were independently reviewed by experts as part of the ICSM Valuation Phase Commitment Review process, which resulted in a go-ahead decision with an identification of several risks to be managed.

Symbiq™ Valuation Phase Summary

The valuation phase focused on the major risks highlighted in the Valuation Commitment Review, such as the multi-channel pump options, the types of programmable therapies, the need for tailorable medication libraries, the display screen and user interface options, and the safety considerations. The valuation phase also elaborated the product concept plan for the most attractive general set of options, including a development plan and operations plan, along with an associated cost analysis, risk analysis, and business case for review at the Foundations Commitment Review.

The multi-channel pump options were explored via several hardware industrial design mockups and early usability tests of the mockups. These included evaluation of such desired capabilities as semi-automatic cassette loading, special pole-mounting hardware, stacking of and total number of channels, and tubing management features. The evaluations led to the overall all choice to use a semi-automatic cassette loading capability with a red-yellow-green LED display to indicate concerns with the loading mechanism and with the pump in general.

Field exercises with prototypes of the pole mountings indicated the need for quick release and activation mechanisms, which were subsequently implemented. Risk analyses of alternative stacking mechanisms and the potential number of channels available established a preference for side-by-side stacking, a decision to develop one and two channel units, and to support a maximum of four channels in a stacked configuration.

The types of programmable therapies considered included continuous delivery for a specified time period, patient weight-based dosing, piggyback or alternating delivery between the two channels, tapered or ramped-rate delivery, intermittent-interval delivery, variable-time delivery, and multistep delivery. These were evaluated via prototyping of the software on a simulated version of the pump complexes and were iterated until satisfactory versions were found.

Evaluation of the tailorable medication libraries addressed the issue that different hard and soft safety limits were needed for dosages in different care settings (e.g., emergency room, intensive care, oncology, pediatric care, etc.) which creates a need for hospitals to program their own soft limits (overridable by nurses with permission codes) and hard limits (no overrides permitted). Stakeholder satisfaction with the tailoring features was achieved via prototype exercises and iteration with representative hospital personnel.

A literature review was conducted to determine the relative advantages and disadvantages of leading input and display technologies, including cost and reliability data. After down-selecting to three leading vendors of touch screen color LCD displays and further investigating their costs and capabilities, a business risk analysis focused on the trade offs between larger displays and customer interest in small-footprint IV pumps. The larger display was selected based on better readability features and the reduced risk of accidental user entries since the larger screen buttons would help to avoid these occurrences. Extensive usability prototyping was done with hardware mockups and embedded software that delivered simulated animated graphic user interface (GUI) displays to a touchscreen interface that was integrated into the hardware case.

The safety risk analysis in the valuation phase followed ISO 14971:2000 standards for medical device design, focusing on Failure Modes and Effects Analyses (FMEAs). This analysis was based on the early high-level design, such as entry of excessive drug doses or misuse of soft safety limit overrides. Subsequent-phase FMEAs would elaborate this analysis, based on the more detailed designs and implementations.

As in the exploration phase, the results of the valuation phase analyses, plans, budgets for the succeeding phases, the resulting revised business case, evidence of solution feasibility, and remaining risks with their risk management plans were reviewed by independent experts and the ICSM Foundations Commitment Review was passed, subject to a few risk level and risk management adjustments.

Symbiq™ Foundations Phase Summary

During the foundations phase, considerable effort was focused on addressing the identified risks such as the need for prototyping the full range of GUI usage by the full range of targeted users, including doctors, home patients, the need for interoperability of the Symbiq™ software with the wide variety of available hospital information systems, and the need for fully detailed FMEAs and other safety analyses. Comparable added effort went into detailed planning for development, production, operations, and support, providing more accurate inputs for business case analyses.

GUI prototyping was done with a set of usability objectives, such as

- 90% of experienced nurses will be able to insert the cassette the first time while receiving minimal training;
- 99% will be able to correct any insertion errors;
- 90% of first time users with no training will be able to power the pump off when directed; and
- 80% of patient users would rate the overall ease of use of the IV pump three or higher on a five-point scale (with five being the easiest to use).

Similar extensive evaluations were done on the efficacy and acceptability of the audio alarms, including the use of a patient and intensive care unit simulator that included other medical devices that produced noises, as well as other distractions such as ringing telephones. These evaluations were used to enable adjustment of the alarms and to make the visual displays easier to understand.

Software interoperability risk management involved extensive testing of representative interaction scenarios between the Symbiq™ software and a representative set of hospital information systems. These resulted in several adjustments to the software interoperability architecture. Also, as the product was being developed as a platform for the next generation of infusion pump products, the software design was analyzed for overspecialization to the initial product, resulting in several revisions. Similar analyses and revisions were performed for the hardware design.

As the design was refined into complete build-to specifications for the hardware and the operational software, the safety analyses were elaborated into complete FMEAs of the detailed designs. These picked up several potential safety issues, particularly involving the off-nominal usage scenarios, but overall confirmed a high assurance level for the safety of the product design. However, the safety risk assessment recommended a risk management plan for the development phase to include continued FMEAs, thorough off-nominal testing of the developing product's hardware and software, and extensive beta-testing of the product at representative hospitals prior to a full release.

This plan and the other development and operations phase plans, product feasibility evidence, and business case analysis updates were reviewed at a Development Commitment Review, which resulted in a commitment to proceed into the development phase.

Symbiq™ Development Phase Systems Engineering Summary

The development phase was primarily concerned with building and testing the hardware and software to the build-to specifications, but continued to have an active systems engineering function to support change management; operations, production, and support planning and preparation; and further safety assurance activities as recommended in the risk management plan for the phase.

For hospital beta-testing, thoroughly bench-tested and working beta versions of the IV pump were deployed in two hospital settings. The hospitals programmed drug libraries for at least two clinical care areas. The devices were used for about four weeks. Surveys and interviews were conducted with the users to capture their "real world" experiences with the pump. Data from the pump usage and interaction memory was also analyzed and compared to the original doctors' orders. The beta tests revealed a number of opportunities to make improvements, including revision of the more annoying alarm melodies and the data entry methods for entering units of medication delivery time in hours or minutes.

Usability testing was also conducted on one of the sets of abbreviated instructions called TIPS cards. These cards serve as reminders for how to complete the most critical tasks. Numerous suggestions for improvement in the TIPS cards themselves, as well as the user interface, came from this work, including how to reset the “Air-in-Line” alarm and how to check all on-screen help text for accuracy.

The above mentioned usability objectives were used as acceptance criteria for the validation usability tests. These objectives were met. For example, the calculated task completion accuracy was 99.66% for all tasks for first time nurse users with minimal training. There were a few minor usability problems uncovered that were subsequently fixed without major changes to the GUI or effects on critical safety related tasks.

The risk analysis was iterated and revised as the product development matured. FMEAs were updated for safety critical risks associated with three product areas: the user interface, the mechanical and electrical subsystems, and the product manufacturing process. Some detailed implementation problems were found and fixed, but overall the risk of continuing into full-scale production, operations, and support was minimal. Systems engineering continued into the operations phase, primarily to address customer change requests and problem reports, and to participate in planning for a broader product line of IV pumps.

Overall, customer satisfaction, sales, and profits from the Symbiq™ IV pump have been strong and satisfaction levels from the management, financial, customer, end user, developer, maintainer, regulatory, and medical-community stakeholders have been quite high (Pew 2007).

Summary

In summary, the Symbiq™ Medical Infusion Pump Case Study provides an example of the use of the systems engineering practices discussed in the SEBoK. As appropriate for a next-generation, advanced technology product, it has a strong focus on risk management, but also illustrates the principles of synthesis, holism, dynamic behavior, adaptiveness, systems approach, progressive entropy reduction, and progressive stakeholder satisfying discussed in Part 2 of the SEBoK. It provides an example of an evolutionary and concurrent systems engineering process, such as the incremental commitment spiral process, and of other knowledge areas discussed in SEBoK Parts 3 and 4, such as system definition, system realization, system engineering management, and specialty engineering.

Medical Radiation

- Lead Authors:
- Heidi Davidz and John Brackett

-

This case study presents system and software engineering issues relevant to the accidents associated with the Therac-25 medical linear accelerator that occurred between 1985 and 1988. The six accidents caused five deaths and serious injury to several patients. The accidents were system accidents that resulted from complex interactions between hardware components, controlling software, and operator functions.

Domain Background

Medical linear accelerators, devices used to treat cancer, accelerate electrons to create high energy beams that can destroy tumors. Shallow tissue is treated with the accelerated electrons. The electron beam is converted to X-ray photons to reach deeper tissues. Accidents occur when a patient is delivered an unsafe amount of radiation.

A radiation therapy machine is controlled by software that monitors the machine's status, accepts operator input about the radiation treatment to be performed, and initializes the machine to perform the treatment. The software turns the electron beam on in response to an operator command. The software turns the beam off whenever the treatment is complete, the operator requests the beam to shut down, or when the hardware detects a machine malfunction. A radiation therapy machine is a reactive system in which the system's behavior is state dependent and the system's safety depends upon preventing entry into unsafe states. For example, the software controls the equipment that positions the patient and the beam. The positioning operations can take a minute or more to execute, thus it is unsafe to activate the electron beam while a positioning operation is in process.

In the early 1980s, Atomic Energy of Canada (AECL) developed the Therac-25, a dual-mode (X-rays or electrons) linear accelerator that can deliver photons at 25 megaelectron volts (MeV) or electrons at various energy levels. The Therac-25 superseded the Therac-20, the previous 20-MeV dual mode accelerator with a history of successful clinical use. The Therac-20 used a DEC PDP-11 (Digital Equipment Corporation Programmed Data Processor) minicomputer for computer control and featured protective circuits for monitoring the electron beam, as well as mechanical interlocks for policing the machine to ensure safe operation. AECL decided to increase the responsibilities of the Therac-25 software for maintaining safety and eliminated most of the hardware safety mechanisms and interlocks. The software, written in PDP-11 assembly language, was partially reused from earlier products in the Therac product line. Eleven Therac-25s were installed at the time of the first radiation accident in June 1985.

The use of radiation therapy machines has increased rapidly in the last 25 years. The number of medical radiation machines in the United States in 1985 was approximately 1000. By 2009 the number had increased to approximately 4450. Some of the types of system problems found in the Therac-25 may be present in the medical radiation devices currently in use. References to more recent accidents are included below.

Case Study Background

The Therac-25 accidents and their causes are well documented in materials from the U.S. and Canadian regulatory agencies (e.g., the U.S. Food and Drug Administration (FDA) and the Canadian Bureau of Radiation and Medical Devices) and in depositions associated with lawsuits brought against AECL. An article by Leveson and Turner (1993) provides the most comprehensive, publicly available description of the accident investigations, the causes of the accidents, and the lessons learned relevant to developing systems where computers control dangerous devices.

Case Study Description

The Therac-25 accidents are associated with the non-use or misuse of numerous system engineering practices, especially system verification and validation, risk management, and assessment and control. In addition, numerous software engineering good practices were not followed, including design reviews, adequate documentation, and comprehensive software unit and integration tests.

The possibility of radiation accidents increased when AECL made the systems engineering decision to increase the responsibilities of the Therac-25 software for maintaining safety and eliminated most of the hardware safety mechanisms and interlocks. In retrospect, the software was not worthy of such trust. In 1983 AECL performed a safety assessment on the Therac-25. The resulting fault tree did include computer failures, but only those associated with hardware; software failures were not considered in the analysis.

The software was developed by a single individual using PDP-11 assembly language. Little software documentation was produced during development. An AECL response to the FDA indicated the lack of software specifications and of a software test plan. Integrated system testing was employed almost exclusively. Leveson and Turner (1993) described the functions and design of the software and concluded that there were design errors in how concurrent processing was handled. Race conditions resulting from the implementation of multitasking also contributed to the accidents.

AECL technical management did not believe that there were any conditions under which the Therac-25 could cause radiation overdoses, and this belief was evident in the company's initial responses to accident reports. The first radiation overdose accident occurred in June 1985 at the Kennestone Regional Oncology Center in Marietta, Georgia, where the Therac-25 had been operating for about 6 months. The patient who suffered the radiation overdose filed suit against the hospital and AECL in October 1985. No AECL investigation of the incident occurred and FDA investigators later found that AECL had no mechanism in place to follow up potential reports of suspected accidents. Additionally, other Therac-25 users received no information that an accident had occurred.

Two more accidents occurred in 1985, including a radiation overdose at Yakima Valley Memorial Hospital in Yakima, Washington that resulted in an accident report to AECL. The AECL technical support supervisor responded to the hospital in early 1986: "After careful consideration, we are of the opinion that this damage could not have been produced by any malfunction of the Therac-25 or by any operator error… there have apparently been no other instances of similar damage to this or other patients."

In early 1986 there were two accidents at the East Texas Cancer Center in Tyler, Texas, both of which resulted in the death of the patient within a few months. On March 21, 1986 the first massive radiation overdose occurred, though the extent of the overdose was not realized at the time. The Therac-25 was shut down for testing the day after the accident. Two AECL engineers, one from the plant in Canada, spent a day running machine tests but could not reproduce the malfunction code observed by the operator at the time of the accident. The home office engineer explained that it was not possible for the Therac-25 to overdose a patient. The hospital physicist, who supervised the use of the machine, asked AECL if there were any other reports of radiation overexposure. The AECL quality assurance manager told him that AECL knew of no accidents involving the Therac-25.

On April 11, 1986 the same technician received the same malfunction code when an overdose occurred. Three weeks later the patient died; an autopsy showed acute high-dose radiation injury to the right temporal lobe of the brain and to the brain stem. The hospital physicist was able to reproduce the steps the operator had performed and measured the high radiation dosage delivered. He determined that data-entry speed during editing of the treatment script was the key factor in producing the malfunction code and the overdose. Examination of the portion of the code responsible for the Tyler accidents showed major software design flaws. Levinson and Turner (1993) describe in detail how the race condition occurred in the absence of the hardware interlocks and caused the overdose. The first report of the Tyler accidents came to the FDA from the Texas Health Department. Shortly thereafter, AECL provided a medical device accident report to the FDA discussing the radiation overdoses in Tyler.

On May 2, 1986 the FDA declared the Therac-25 defective and required the notification of all customers. AECL was required to submit to the FDA a corrective action plan for correcting the causes of the radiation overdoses. After multiple iterations of a plan to satisfy the FDA, the final corrective action plan was accepted by the FDA in the summer of 1987. The action plan resulted in the distribution of software updates and hardware upgrades that reinstated most of the hardware interlocks that were part of the Therac-20 design.

AECL settled the Therac-25 lawsuits filed by patients that were injured and by the families of patients who died from the radiation overdoses. The total compensation has been estimated to be over $150 million.

Summary

Leveson and Turner (1993) describe the contributing factors to Therac-25 accidents: “We must approach the problems of accidents in complex systems from a systems-engineering point of view and consider all contributing factors." For the Therac-25 accidents, the contributing factors included:

- management inadequacies and a lack of procedures for following through on all reported incidents;
- overconfidence in the software and the resulting removal of hardware interlocks (causing the software to be a single point of failure that could lead to an accident);
- less than acceptable software engineering practices; and
- unrealistic risk assessments along with over confidence in the results of those assessments.

Recent Medical Radiation Experience

Between 2009 and 2011, The New York Times published a series of articles by Walter Bogdanich on the use of medial radiation, entitled “Radiation Boom" (2011).

The following quotations are excerpts from that series:

> *Increasingly complex, computer-controlled devices are fundamentally changing medical radiation, delivering higher doses in less time with greater precision than ever before.” But patients often know little about the harm that can result when safety rules are violated and ever more powerful and technologically complex machines go awry. To better understand those risks, The New York Times examined thousands of pages of public and private records and interviewed physicians, medical physicists, researchers and government regulators. The Times found that while this new technology allows doctors to more accurately attack tumors and reduce certain mistakes, its complexity has created new avenues for error — through software flaws, faulty programming, poor safety procedures or inadequate staffing and training. . . .*
>
> *Linear accelerators and treatment planning are enormously more complex than 20 years ago,’ said Dr. Howard I. Amols, chief of clinical physics at Memorial Sloan-Kettering Cancer Center in New York. But hospitals, he said, are often too trusting of the new computer systems and software, relying on them as if they had been tested over time, when in fact they have not. . . .*
>
> *Hospitals complain that manufacturers sometimes release new equipment with software that is poorly designed, contains glitches or lacks fail-safe features, records show. Northwest Medical Physics Equipment in Everett, Wash., had to release seven software patches to fix its image-guided radiation treatments, according to a December 2007 warning letter from the F.D.A. Hospitals reported that the company’s flawed software caused several cancer patients to receive incorrect treatment, government records show.*

Design for Maintainability

- Lead Author:
- Rick Adcock

-

This article describes an example of where systems thinking led to a much more practical solution to a common problem. For additional information, refer to Systems Thinking.

This article is excerpted and condensed from Johnson, S. 2010. *Where Good Ideas Come From: The Natural History of Innovation*. New York, NY, USA: Riverhead Books. pp. 25-28.

Background

In the late 1870s, a Parisian obstetrician named Stephane Tarnier was visiting the Paris Zoo where they had farm animals. While there, he conceived the idea of adapting a chicken incubator to use for human newborns, and he hired "the zoo's poultry raiser to construct a device that would perform a similar function for human newborns." At the time infant mortality was staggeringly high "even in a city as sophisticated as Paris. One in five babies died before learning to crawl, and the odds were far worse for premature babies born with low birth weights." Tarnier installed his incubator for newborns at Maternité de Paris and embarked on a quick study of five hundred babies. "The results shocked the Parisian medical establishment: while 66 percent of low-weight babies died within weeks of birth, only 38 percent died if they were housed in Tarnier's incubating box. … Tarnier's statistical analysis gave newborn incubation the push that it needed: within a few years the Paris municipal board required that incubators be installed in all the city's maternity hospitals." …

Purpose

"Modern incubators, supplemented with high-oxygen therapy and other advances, became standard equipment in all American hospitals after the end of World War II, triggering a spectacular 75 percent decline in infant mortality rates between 1950 and 1998."… "In the developing world, however, the infant mortality story remains bleak. Whereas infant deaths are below ten per thousand births throughout Europe and the United States, over a hundred infants die per thousand (births) in countries like Liberia and Ethiopia, many of them premature babies that would have survived with access to incubators.

Challenges

But modern incubators are complex, expensive things. A standard incubator in an American hospital might cost more than $40,000 [about €30,000]. But the expense is arguably the smaller hurdle to overcome. Complex equipment breaks and when it breaks you need both the technical expertise to fix it and replacement parts. In the year that followed the 2004 Indian Ocean tsunami, the Indonesian city of Meulaboh received eight incubators from a range of international relief organizations. By late 2008, when an MIT professor named Timothy Prestero visited the hospital, all eight were out of order, the victims of power surges and tropical humidity, along with the hospital staff's inability to read the English repair manual. The Meulaboh incubators were a representative sample: some studies suggest that as much as 95 percent of medical technology donated to developing countries breaks within the first five years of use.

Systems Engineering Practices

"Prestero had a vested interest in those broken incubators, because the organization he founded, Design that Matters, had been working for several years on a scheme for a more reliable, and less expensive, incubator, one that recognized complex medical technology was likely to have a very different tenure in a developing world context than it would in an American or European hospital. Designing an incubator for a developing country wasn't just a matter of creating something that worked; it was also a matter of designing something that would break in a non-catastrophic way. You couldn't guarantee a steady supply of spare parts, or trained repair technicians. So instead, Prestero and his team decided to build an incubator out of parts that were already abundant in the developing world. The idea had originated with a Boston doctor named Jonathan Rosen, who had observed that even the smaller towns of the developing world seemed to be able to keep automobiles in working order. The towns might lack air conditioning and laptops and cable television, but they managed to keep their Toyota 4Runners on the road. So Rosen approached Prestero with an idea: What if you made an incubator out of automobile parts?

Lessons Learned

"Three years after Rosen suggested the idea, the Design that Matters team introduced a prototype device called NeoNurture. From the outside, it looked like a streamlined modern incubator, but its guts were automotive. Sealed-beam headlights supplied the crucial warmth; dashboard fans provided filtered air circulation; door chimes sounded alarms. You could power the device via an adapted cigarette lighter, or a standard-issue motorcycle battery. Building the NeoNurture out of car parts was doubly efficient, because it tapped both the local supply of parts themselves and the local knowledge of automobile repair. These were both abundant resources in the developing world context, as Rosen liked to say. You didn't have to be a trained medical technician to fix the NeoNurture; you didn't even have to read the manual. You just needed to know how to replace a broken headlight."

Space System Examples

Global Positioning System

- Lead Authors:
- Heidi Davidz, Richard Freeman, and Alice Squires
- Contributing Authors:
- Tom Hilburn and Brian White

-

The Global Positioning System (GPS) case study was developed by the United States Air Force Center for Systems Engineering (AF CSE) located at the Air Force Institute of Technology (AFIT). The GPS is a space-based radio-positioning system. A constellation of twenty-four satellites, including three spares, comprise the overall system which provides navigation and timing information to military and civilian users worldwide. GPS satellites, in one of six Earth orbits, circle the globe every twelve hours, emitting continuous navigation signals on two different L-band frequencies. The system consists of two other major segments: a world-wide satellite control network, and the GPS user equipment that can either be carried by a human user or integrated into host platforms such as ships, vehicles, or aircraft.

This case study discussion is based on the original source (O'Brien and Griffin 2007), which provides useful insights into what we might consider a "traditional" SE application. A second global positioning case study looks at the same case study from the perspectives of system of systems (sos) engineering and enterprise systems engineering (ese).

Domain Background

When looking at the Global Positioning System (GPS), it would be difficult to imagine another system that relies so heavily upon such a wide range of domains, with the possible exception of the World Wide Web (WWW). Additionally, the various systems operating within these domains must all function together flawlessly to achieve success. It is evident from reading this case study that it directly relates to the following domains:

- aerospace;
- space;
- communications; and
- transportation.

This is also an example of systems of systems (SoS) and is considered an innovative technology.

The GPS case study includes a detailed discussion of the development of the GPS and its components, as well as other applicable areas. The reader of this study will gain an increased understanding of the effect that GPS has on military and commercial industries in the context of the systems engineering support required to achieve success.

Case Study Background

The United States Air Force Center for Systems Engineering (AF CSE), established in 2002 at the Air Force Institute of Technology (AFIT), was tasked to develop case studies focusing on the application of systems engineering principles within various aerospace programs. The GPS case study (O'Brien and Griffin 2007) was developed by AFIT in support of systems engineering graduate school instruction. The cases are structured using the Friedman-Sage framework (Friedman and Sage 2003; Friedman and Sage 2004, 84-96), which decomposes a case into contractor, government, and shared responsibilities in the following nine concept areas:

1. Requirements Definition and Management
2. Systems Architecture Development
3. System/Subsystem Design
4. Verification/Validation
5. Risk Management
6. Systems Integration and Interfaces
7. Life Cycle Support
8. Deployment and Post Deployment
9. System and Program Management

The Friedman-Sage framework (2004) is provided in Appendix A of the case study. This case study is an example where the government - specifically the JPO Systems Engineering Directorate - bore the responsibility for systems integration and configuration management. That is, the government played more than an oversight role in the systems engineering of the GPS system of systems. As mentioned in the case study, JPO developed the CONOPs, mission analysis, requirements and design analysis including security, and developed their own approach to the cryptology methodology. JPO coordinated the Configuration Control Board (CCB) chaired by the Program Director. JPO was also responsible for Level I ICDs and system design configurations; where the contractors were responsible for the system architecture and ICDs within their segment.

Case Study Description

The “Global Positioning System - Systems Engineering Case Study” describes the application of systems engineering during the concept validation, system design and development, and production phases of the GPS program (O'Brien and Griffin 2007). The case examines the applied systems engineering processes, as well as the interactions of the GPS joint program office (JPO), the prime contractors, and the plethora of government agencies that were associated with the program’s development and fielding. The systems engineering process is traced from the initiation of studies and the development of key technologies, which established the vision of a satellite navigation system in the 1960s, through to the multiphase joint program that resulted in a fully operational capability release in 1995. This case study does not cover system enhancements incorporated through Blocks IIM, IIF, and III.

The GPS case study derived four learning principles (LPs) that explain the more broadly applicable areas of systems engineering knowledge that are addressed by the case study. These four LPs relate strongly to the SEBoK in the following areas:

- enabling individuals (LP1);
- configuration management (LP2);
- enabling the organization (LP3); and
- risk management (LP4).

Additionally, the GPS case study contains a thorough overview of life cycle management and exemplifies systems thinking principles.

Enabling Individuals

Learning Principle 1: Programs must strive to staff key positions with domain experts.

From the program management team, to the systems engineering, design, manufacturing, and operations teams, the individuals on the program were well-versed in their disciplines and all possessed a systems view of the program. While communications, working relationships, and organization were important, it was the ability of the whole team at all levels to understand the implications of their work on the system that was vital. Their knowledge-based approach for decision making had the effect of shortening the decision cycle because the information was understood and the base and alternative solutions were accurately presented.

Configuration Management

Learning Principle 2: The systems integrator must rigorously maintain program baselines.

The joint program office (JPO) retained the role of managing and controlling the system specification and, therefore, the functional baseline. The JPO derived and constructed a mutually-agreed-to set of system requirements that became the program baseline in 1973. While conducting the development program, the GPS team was able to make performance, risk, cost, and trade analyses against the functional baseline to control both risk and cost. The JPO was fully cognizant of the implications of the functional requirements on the allocated baseline because they managed the interface control working group process. Managing that process gave them first-hand knowledge and insight into the risks at the lowest level. The individual with the system integrator role must rigorously maintain the system specification and functional baseline. There must be appropriate sharing of management and technical responsibilities between the prime contractor and their government counterparts to ensure success.

Enabling the Organization

Learning Principle 3: Achieving consistent and continuous high-level support and advocacy helps funding stability, which impacts systems engineering stability.

Consistent, continuous high-level support provides the requirements and assists funding stability. In this role, the Office of the Secretary of Defense (OSD) provided advocacy and sourced the funding at critical times in the program, promoted coordination among the various services, and reviewed and approved the GPS JPO system requirements. The OSD played the central role in the establishment and survivability of the program. The GPS JPO had clear support from the Director of Defense Development, Research, and Engineering, Dr. Malcolm Currie, and program support from the Deputy Secretary of Defense, Dr. David Packard. Clearly, the armed services – particularly the Navy and the Air Force early on, and later the Army – were the primary users of GPS and the eventual customers. However, each armed service had initial needs for their individual programs, or for the then-current operational navigation systems. Additionally, the secretary of the Air Force provided programmatic support to supply manpower and facilities.

Risk Management

Learning Principle 4: Disciplined and appropriate risk management must be applied throughout the life cycle.

The GPS program was structured to address risk in several different ways throughout the multiphase program. Where key risks were known up front, the contractor and/or the government utilized a classic risk management approach to identify and analyze risk, as well as develop and track mitigation actions. These design (or manufacturing/launch) risks were managed by the office who owned the risks. Identified technical risks were often tracked by technical performance measures (such as satellite weight and software lines of codes) and addressed at weekly chief engineer's meetings.

Serving in the clear role of program integrator allowed the JPO to sponsor risk trade studies at the top level. The JPO would issue study requests for proposals to several bidders for developing concepts and/or preliminary designs. Then, one contractor would be down-selected and the process would continue. This approach provided innovative solutions through competition, as well as helped in defining a lower risk, more clearly defined development program for the fixed-price contracts approach that was being used for development and production.

As the system integrator, the JPO was also closely involved with technical development. To identify unforeseeable unique technical challenges, the JPO would fund studies to determine the optimal approaches to new issues. There were schedule risks associated with the first launch due to unforeseen Block II issues with respect to the space vehicle and control segments (software development). Although it was a catastrophic event, the Challenger accident actually provided much needed schedule relief. Using decision analysis methodology led the JPO to an alternative approach to develop the expendable launch vehicle for the Block II satellites.

Good communication, facilitated by cooperative working relationships, was a significantly positive (though intangible) factor in the success of the GPS program, regardless of whether it was between the contractors and the government (JPO or other agencies), or between contractors and sub-contractors. A true team environment also played a significant role in reducing risk, especially considering the plethora of government agencies and contractors that were involved in the effort.

Life Cycle Management

The GPS case study takes the reader through the initial concept of GPS (March 1942) all the way to the development, production, and operational capability of the system. The current GPS program traces its heritage to the early 1960s when Air Force Systems Command initiated satellite-based navigation systems analyses conducted by The Aerospace Corporation. The case study follows the execution of the GPS program from the inception of the idea to the full operational capability release on April 27th, 1995. The concentration of the case study is not limited to any particular period, and the learning principles come from various times throughout the program's life.

Systems Thinking

The GPS case study highlights the need for systems thinking throughout. GPS satellites, in one of six Earth orbits, circle the globe every twelve hours. These satellites emit continuous navigation signals on two different L-band frequencies. The system consists of two other major segments: a world-wide satellite control network and the GPS user equipment that can either be carried by a human user, or integrated into host platforms such as ships, vehicles, or aircraft. The ability to conceive, develop, produce, field, and sustain the GPS demands the highest levels of systems thinking.

Summary

The GPS case study is useful for global systems engineering learning and provides a comprehensive perspective on the systems engineering life cycle. The study is applicable for detailed instruction in the following areas:

- enabling individuals;
- configuration management;
- enabling the organization;
- risk management;
- life cycle management; and
- systems thinking.

The GPS case study revealed that key Department of Defense personnel maintained a clear and consistent vision for this unprecedented, space-based navigation capability. The case study also revealed that good fortune was enjoyed by the JPO as somewhat independent, yet critical, space technologies matured in a timely manner.

Although the GPS program required a large degree of integration, both within the system and external to the system, amongst a multitude of agencies and contractors, the necessary efforts were taken to achieve success.

Lastly, the reader of the GPS case study will gain an increased understanding of the effect that GPS has on the military and commercial industries in the context of the systems engineering support required to achieve success. The system was originally designed to help "drop five bombs in one hole" which defines the accuracy requirement in context-specific terms. The GPS signals needed to be consistent, repeatable, and accurate to a degree that, when used by munitions guidance systems, would result in the successful delivery of multiple, separately-guided munitions to virtually the identical location anywhere at any time across the planet. Forty to fifty years ago, very few outside of the military recognized the value of the proposed accuracy and most non-military uses of GPS were not recognized before 1990. GPS has increasingly grown in use and is now used every day.

Global Positioning System II

- Lead Author:
- Brian White

-

This article highlights some of the differences between the so-called classical, traditional, or conventional systems engineering (SE) approaches and the newer, and, as yet, less defined principles of system of systems (SoS) engineering (SoSE), enterprise systems engineering (ESE), and/or complex systems engineering (CSE) or complex adaptive systems engineering (Gorod et al. 2015). The topic is still somewhat controversial, especially considering those that are skeptical that broader views of SE might work better when one is immersed in trying to cope with our most difficult problems. Indeed, the lack of a unified theory of SE is one of the prime motivations for producing and analyzing case studies to develop more knowledge of what seems to work, what does not seem to work, and reasons why, really challenging SE environments.

For addition information, refer to Systems Engineering: Historic and Future Challenges, Systems Engineering and Other Disciplines, Enterprise Systems Engineering, and System of Systems Engineering.

Rather than modifying the previous discussion of the Global Positioning System Case Study in SEBoK, the focus is on comparing and contrasting the older and newer forms of SE by commenting on quotations from the original case study source documents (O'Brien and Griffin 2007).

Preface

The original case study begins by describing systems engineering (SE) principles. For example,

> System requirements are critical to all facets of successful system program development. First, system development must proceed from a well-developed set of requirements. Second, regardless of the evolutionary acquisition approach, the system requirements must flow down to all subsystems and lower-level components. And third, the system requirements must be stable, balanced, and must properly reflect all activities in all intended environments. However, system requirements are not unchangeable. As the system design proceeds, if a requirement or set of requirements is proving excessively expensive to satisfy, the process must rebalance schedule, costs, and performance by changing or modifying the requirements or set of requirements. (O'Brien and Griffin 2007, p. 9)

The Global Positioning System (GPS), including its multi-various applications, was developed over many years as the result of the efforts of a host of contributors. It is very difficult to believe that the classical, traditional or conventional systems engineering approach described in the above paragraph (especially those phrases highlighted in bold by the present authors) was truly responsible for this remarkable achievement that so profoundly impacts our lives. Rather, some more advanced form of systems engineering (SE), that might be called system of systems (SoS) engineering (SoSE), enterprise systems engineering (ESE), or complex (adaptive) systems engineering (CSE), or a blend and/or combination of these approaches or methodologies, had to be responsible. This premise is supported explicitly and repeatedly in the following case study revision using bold font.

Continuing, the following quoted paragraphs seem flawed in several places highlighted in bold. The bold phrases might be replaced by the phrases in brackets […]. Such brackets might also include other editorial comments of the present authors.

> Systems engineering includes making key system and design trades early in the process to establish the system architecture. ‘”These architectural artifacts”’ [This architecture] can depict any new system, legacy system, modifications thereto, introduction of new technologies, and overall system-level behavior and performance. Modeling and simulation are generally employed to organize and assess architectural system alternatives at this stage. System and subsystem design follows the functional [system] architecture [as defined from a functional point of view]. System architectures designs are modified if elements are too risky, expensive, or time-consuming. (O'Brien and Griffin 2007, p. 9)

A good architecture, once established, should guide systems development, and not change very much, if at all, at least compared to possible changes in the system design, which, of course, can evolve as one learns more about the problem and potential solutions that may increase the system's capability. Thus, it is crucial to not confuse architecture with designs instantiating the architecture, contrary to what seems to be the case in (Ricci, et al. 2013).

> Important to the efficient decomposition and creation of functional and physical architectural designs are the management of interfaces and the integration of subsystems. Interface management and integration is applied to subsystems within a system or across a large, complex system of systems. Once a solution is planned, analyzed, designed, and constructed, validation and verification take place to ensure satisfaction of requirements. Definition of test criteria, measures of effectiveness (MOEs), and measures of performance (MOPs) are established as part of the requirements process, taking place well before any component/subsystem assembly design and construction occurs. (O'Brien and Griffin 2007, p. 10)

In the quoted paragraph just above, bold phrases note the emphasis on a reductionist approach, reductionism, where great attention is paid to the subsystems and managing the interfaces among them. This is the antithesis of a holistic approach where one concentrates on the whole system, recognizing that it is difficult to identify overall system behavior as depending on any particular subsystem or set of subsystems. In a truly complex system that is continually evolving, the above-mentioned requirements process is flawed because the system is continually changing, i.e., the system is evolutionary; the requirements are either ill-defined at the outset, or are modified

because stakeholderschange their minds, or become somewhat irrelevant because the system environment changes.

> There are several excellent representations of the [usual traditional or conventional] systems engineering process presented in the literature. These depictions present the current state of the art in maturity and evaluation of the systems engineering process. One can find systems engineering process definitions, guides, and handbooks from the International Council on Systems Engineering (INCOSE), European Industrial Association (EIA), Institute of Electrical and Electronics Engineers (IEEE), and various Department of Defense (DoD) agencies and organizations. They show the process as it should be applied [Really? In all situations?] by today's experienced practitioner. One of these processes, long used by the Defense Acquisition University (DAU), is [a model] not accomplished in a single pass. This iterative and nested process gets repeated to the lowest level of definition of the design and its interfaces. (O'Brien and Griffin 2007, p. 10)

The above description appears to be written with pride without any acknowledgement that this SE methodology might fail to work if applied according to these guidelines, or that there might be new SE techniques that could be more effective in some situations. Again, this reflects a reductionist approach that ignores holism and emergent properties that might not be explained even when thoroughly understanding the systems components and their interactions. On the positive side, the next paragraph suggests how the world is changing and hints that something more is needed. Nevertheless, the advice seems to be oriented toward applying the existing SE discipline more vigorously instead of seeking new methods that might be more effective.

> The DAU model, like all others, has been documented in the last two decades, and has expanded and developed to reflect a changing environment. Systems are becoming increasingly complex internally and more interconnected externally. The process used to develop aircraft and systems of the past was effective at the time. It served the needs of the practitioners and resulted in many successful systems in our inventory. Notwithstanding, the cost and schedule performance of the past programs are replete with examples of well-managed programs and ones with less-stellar execution. As the nation entered the 1980s and 1990s, large DoD and commercial acquisitions experienced overrunning costs and slipping schedules. The aerospace industry and its organizations were becoming larger and were more geographically and culturally distributed. Large aerospace companies have worked diligently to establish common systems engineering practices across their enterprises. However, because of the mega-trend of teaming in large (and some small) programs, these common practices must be understood and used beyond the enterprise and to multiple corporations. It is essential that the systems engineering process govern integration, balance, allocation, and verification, and be useful to the entire program team down to the design and interface level. (O'Brien and Griffin 2007, p. 11)

Finally, in the next paragraph, there is a suggestion that SE could be made more sophisticated but there is no mention of addressing people problems or advocating a broader transdisciplinary approach.

> Today, many factors overshadow new acquisition; including system-of-systems (SoS) con- text, network centric warfare and operations, and rapid growth in information technology. These factors are driving a more sophisticated systems engineering process with more complex and capable features, along with new tools and procedures. One area of increased focus of the systems engineering process is the informational systems architectural definitions used during system analysis. This process, described in DoD Architectural Framework (DoDAF), emphasizes greater reliance on reusable architectural views describing the system context and concept of operations, interoperability, information and data flows, and network service-oriented characteristics. (O'Brien and Griffin 2007, p. 11)

The last two sections of the systems engineering principles portion of the original case study address case studies themselves, mainly for academic purposes, to help people appreciate systems engineering principles, and the framework used in the case study, namely the rather narrowly defined Friedman-Sage framework that will be discussed briefly in Section II below.

The treatment of the reason for case studies is quite good in that it talks about the benefits of applying systems engineering principles, as highlighted from real-world examples of what works and what does not. Except near the end, where there is allusion to the possibility of new endeavor systems engineering principles, the principles espoused tend to be traditional or conventional.

On the other hand, based upon the original case study (O'Brien and Griffin 2007), if one views the boundary of the GPS system to include primarily the technology associated with the GPS space segment and its controlling ground network, then it can be assumed that system was likely implemented primarily by following traditional or conventional systems engineering processes. If one takes this viewpoint, then all of the above criticism which attempts to point out some of the shortcomings of conventional systems engineering, may seem vacuous at best, or politically incorrect at worst. It may well be that many would rather not denigrate the original GPS case study by exposing it to the possibilities of a broader system engineering approach.

Unless otherwise indicated, as the present authors have already been doing, unchanged quotations from the existing SEBoK are indented below. Modifications to such quotations are shown in brackets [...]; deletions are not necessarily shown explicitly.

Background

> The Global Positioning System (GPS) case study was developed by the United States Air Force Center for Systems Engineering (AF CSE) located at the Air Force Institute of Technology (AFIT). The GPS is a space-based radio-positioning system. A constellation of twenty-four satellites, including three spares, comprise the overall system which provides navigation and timing information to military and civilian users worldwide. GPS satellites, in one of six Earth orbits, circle the globe every twelve hours, emitting continuous navigation signals on two different L-band frequencies. The system consists of two other major segments: a world-wide satellite control network, and the GPS user equipment that can either be carried by a human user or integrated into host platforms such as ships, vehicles, or aircraft.

A user needs to receive signals from at least four GPS satellites simultaneously (satellite orbital positions and terrestrial terrain blockage can be issues that degrade performance) to determine one's position in three dimensions; the altitude determination is typically less accurate than the other two dimensions.

> When looking at [GPS], it would be difficult to imagine another system that relies so heavily upon such a wide range of [domains containing systems that must interact effectively to achieve successful GPS operation]. It is evident that [GPS directly relates to many domains and applications including:

- position location and tracking
- time synchronization
- navigation
- transportation
- times of arrival
- air traffic management
- situational awareness
- jam-resistant communications
- business and commerce
- farming
- aerospace
- sensing nuclear detonations from space
- military war-fighting
- targeting
- weapons delivery
- etc.].

> [GPS is] an example of [a collaborative (Dahmann, et al. 2008) systems of systems (SoS)]. As such, no one is in charge, and the capabilities (not requirements) flow from the bottom-up, as opposed to top-down.

Purpose

> The GPS case study includes a detailed discussion of the development of the GPS and its components, as well as other applicable areas. The reader of this study will gain an increased understanding of the effect that GPS has on military and commercial industries in the context of the systems engineering support required to achieve success.

This may be, but the principal purpose of this revised case study is to suggest a broader view of GPS that discusses signature aspects of SoS, enterprises, and complex systems, and emphasizes SoSE, ESE, and CSE.

> [AF CSE] was tasked to develop case studies focusing on the application of [SE] principles within various aerospace programs. The GPS case study [was developed in support of SE] graduate school instruction using the Friedman-Sage framework (Friedman and Sage 2003) (Friedman and Sage 2004).]

However, the Friedman-Sage framework involves only two contractual stakeholders, the Government and the contractor; further, the framework is limited to the traditional or conventional SE life cycle which mainly treats activities in a linear instead of nonlinear fashion; still further, only risks are considered, not a balance of risk and opportunity. Thus, the present authors believe a broader framework embracing SoSE, ESE, and CSE is more appropriate.

Challenges

In the original case study, the first highly technical section (Section 2) was the system description. The original idea derived from trying to determine the precise orbital parameters of the first artificial satellites, such as Sputnik, launched by the Soviets in 1957. Researchers at Johns Hopkins realized the inverse, that if one knew precisely the orbital parameters, the locations of ground stations receiving satellite signals could be determined quite accurately. (O'Brien and Griffin 2007, p. 20.)

GPS got its start in the early 70s (O'Brien and Griffin 2007, p. 19), building upon several previous satellite navigation systems. The primary motive was very accurate position information for the purposes of military applications. For example, the U.S. Air Force wanted to deliver nuclear weapons from bombers with unprecedented accuracy and precision. (O'Brien and Griffin 2007, p. 29)

With such an intense interest from the military, the first real challenge, other than the many technical challenges of making GPS work as well as envisioned, might have been the question of how to make GPS available to the civilian community so they could share the benefits. The study claimed that the system was always offered for civilian use, albeit with some charge. After the Korean airliner went astray and got shot down by a Soviet interceptor aircraft, President Reagan made GPS officially available for civilian use free of charge. (O'Brien and Griffin 2007, p. 14)

The second challenge could be associated with preserving precision capabilities for the military only, and relegating course acquisition (C/A) accuracy to the civilian community. (O'Brien and Griffin 2007, p. 15) Later this dichotomy was essentially eliminated with the realization that a differential GPS configuration involving a fixed ground station with a precisely known location will yield great accuracy. (Kee, et al. 1991)

The GPS satellites used space-borne atomic clocks. To alleviate the need for updating these clocks too often, a successful effort was initiated to revise the international time standard which ended up using relatively infrequent "leap seconds". (O'Brien and Griffin 2007, p. 23) Even these are still annoying for many other applications, such as the continual need to achieve precise synchronization of frequency-hopping radios.

An organizational challenge of inter-service rivalries was overcome with the formation of the Joint Program Office (JPO). (O'Brien and Griffin 2007, p. 25.)

In the early days of satellite communication systems, for example, the satellites were quite small and low powered while the terminals were large and high-powered. By the time GPS came along, the satellites are getting bigger and more sophisticated. Then the challenge to develop relatively low-cost terminals, particularly for mobile users, greatly increased. (O'Brien and Griffin 2007, p. 29)

A small but interesting challenge was the definition of system of systems (SoS). It was decided that GPS was an SoS because it involved three independent systems, namely, the space vehicle (SV), the control segment (CS), and the user equipment (UE), that "merely" had to interface with each other. (O'Brien and Griffin 2007, p. 30)

Continually changing requirements is usually a problem, although in this case the requirements did not change as often as they could have. (O'Brien and Griffin 2007, p. 31)

Difficulties of defining and updating the many GPS interfaces was largely overcome by the GPS program director, Col. Brad Parkinson, when he convinced his own management, Gen. Schultz at Space and Missile Systems Office (SAMSO) (which eventually became the Space Division) that GPS ought to be defined solely by the signal-structure-in-space and not the physical interfaces. (O'Brien and Griffin 2007, p. 31)

Systems Engineering Practices

> Although the systems engineering process in Phase I has been discussed previously, this section will expand on the concepts. For example, one of the user equipment contractors was technically competent, but lacked effective management. The JPO strongly suggested that a systems engineering firm be hired to assist the contractor in managing the program and they agreed. (O'Brien and Griffin 2007, p. 42)

There did not seem to be any mention of what SE firm was hired, if any. The Aerospace Corporation, a non-profit Federally Funded Research and Development Center (FFRDC), which had such a key role in the run-up to GPS was also prominently and centrally involved in development phase of this humungous project. (O'Brien and Griffin 2007, pp. 20, 22, 25, 33, 34, 40, 41, 44, 48, 50-52, 56, 57, 62, 63, 64, 66, 67, 71)

Lessons Learned

> Communications was a key ingredient that was fostered throughout GPS development. (O'Brien and Griffin 2007, p. 71)

Yes, from reading the original case study there seems to have been a lot of cooperation among the various organizations, more so than might have been expected in a less compelling case.

> Several precepts or foundations of the Global Positioning Satellite program are the reasons for its success. These foundations are instructional for today's programs because they are thought-provoking to those who always seek insight into the program's progress under scrutiny. These foundations of past programs are, of course, not a complete set of necessary and sufficient conditions. For the practitioner, the successful application of different systems engineering processes is required throughout the continuum of a program, from the concept idea to the usage and eventual disposal of the system. Experienced people applying sound systems engineering principles, practices, processes, and tools are necessary every step of the way. Mr. Conley, formerly of the GPS JPO, provided these words: "Systems engineering is hard work. It requires knowledgeable people who have a vision of the program combined with an eye for detail." (O'Brien and Griffin 2007, p. 72)

In very complex systems engineering efforts of this type, it is also important to explore new techniques that attempt to deal with "soft" issues involving people. Those that seem to work can be added to the systems engineering process collection.

> Systems engineering played a major role in the success of this program. The challenges of integrating new technologies, identifying system requirements, incorporating a system of systems approach, interfacing with a plethora of government and industry agencies, and dealing with the lack of an

> operational user early in the program formation required a strong, efficient systems engineering process. The GPS program embedded systems engineering in their knowledge-base, vision, and day-to-day practice to ensure proper identification of system requirements. It also ensured the allocation of those requirements to the almost-autonomous segment developments and beyond to the subcontractor/vendor level, the assessments of new requirements, innovative test methods to verify design performance to the requirements, a solid concept of operations/mission analysis, a cost-benefit analysis to defend the need for the program, and a strong system integration process to identify and control the "hydra" of interfaces that the program encountered. The program was able to avoid major risks by their acquisition strategy, the use of trade studies, early testing of concept designs, a detailed knowledge of the subject matter, and the vision of the program on both the government and contractor side. (O'Brien and Griffin 2007, p. 72)

This well summarizes the successful systems engineering approach utilized in GPS. Another element of achieving overall balance is the pursuit of opportunities as the "flipside" of risk mitigation.

Finally, here is the list of academic questions offered in the original case study.

> QUESTIONS FOR THE STUDENT (O'Brien and Griffin 2007, p. 73) The following questions are meant to challenge the reader and prepare for a case discussion.

- Is this program start typical of an ARPA/ DARPA funded effort? Why or why not?
- Have you experienced similar or wildly different aspects of a Joint Program?
- What were some characteristics that should be modeled from the JPO?
- Think about the staffing for the GPS JPO. How can this be described? Should it be duplicated in today's programs? Can it?
- Was there anything extraordinary about the support for this program?
- What risks were present throughout the GPS program. How were these handled?
- Requirement management and stability is often cited as a central problem in DoD acquisition. How was this program like, or [un]like, most others?
- Could the commercial aspects of the User Equipment be predicted or planned? Should the COTS aspect be a strategy in other DoD programs, where appropriate? Why or why not?

> Other questions might be: What possible influences did the demand for or offering to the public of this GPS capability entail? What differences in the development of GPS might have emerged if the public was more aware of the potential applications for their benefit at the outset?

Russian Space Agency Project Management Systems

-

This article is based around a **Russian space agency Project Management Systems case study** (Rzevski and Skobelev, 2014). The case study focuses on the development of a Real-Time Complex Adaptive Project Management System capable of effectively managing multiple related projects collectively contributing to a defined Enterprise Value.

Background

The essence of every management system should be the same: the allocation of human, physical, financial and intellectual (knowledge) resources to demands (tasks) with the aim of increasing the specified Enterprise Value, where the Enterprise Value is a system of values such as profit, market share, business sustainability, quality of service to customers, quality of working conditions for employees, quality of life in the community, etc. The key difference between the management of a business and management of a project is that businesses are continuously evolving processes whilst projects have specified beginnings and ends.

Standard challenges for project management are:

- Stringent budgets and deadlines
- High competition for limited resource availability such as up-to-date domain knowledge, skills and advanced productivity tools
- Functional organization, which inevitably impedes interdepartmental cooperation
- Bureaucratic management, which is more concerned with lines of command and reporting than with the full use of a project member's initiative and creativity and which negatively affects their motivation
- Rigid project planning, which leads to a rapid divergence between the project plan and reality

Large enterprises commonly operate several projects concurrently. What is best for an individual project is not always best for the enterprise and therefore it is necessary to implement coordination of concurrently run projects with the objective of significantly increasing Enterprise Value.

There are two new key problems, which the 21st century brought to us.

The first is the rapidly increasing complexity of the Internet-based global market, which creates frequent unpredictable disruptive events. This requires real-time adaptive project management, for which there is at present no precedent.

The second is the replacement of capital with knowledge as the key business resource in the economy in which the wealth created by knowledge services is greater than wealth created by producers of goods. There is at present no management system capable of discovering, processing, storing and allocating knowledge to project tasks.

Purpose

The client for this case study was one of the key space technology organizations in Russia, their equivalent of NASA, which operates, at any time, many concurrent mission critical projects.

The purpose of the project management system was to enable the client to effectively manage several related projects (at least ten), collectively contributing to the specified Enterprise Value, with the following requirements:

- Each project may consist of up to 5,000 constituent tasks
- Project members may have different backgrounds and skills and may belong to diverse business cultures
- Project members must have an opportunity to contribute to decision making processes, which affects their domain of work (distributed decision making)
- Both project management and project members must have readily available and up-to-date information on, respectively, project and individual progress, productivity and achievements of goals
- The allocation of resources to tasks must consider 4 types of resources, namely, human, physical, financial and knowledge
- Availability of resources for and constituent tasks of each project may change with short notice and these changes must be rapidly incorporated into the system
- Projects will be subjected to frequent disruptive events such as non-arrival of expected orders, arrival of unexpected orders, sudden and unforeseen emergence of external/internal competitors, cancellations, changes in task specifications, delays, failures, no-shows, etc.
- Rules and regulations governing projects are likely to change rather frequently and any change in rules and regulations must be incorporated immediately and easily into the relevant project management system
- Any discrepancy between project plans and reality in the field must be continuously monitored and rapidly detected and reported
- Projects may cooperate and/or compete for resources in order to increase specified Enterprise Value

A thorough analysis of the client's requirements led to the conclusion that it is necessary to develop a real-time, complex adaptive project management system capable of cooperating and/or competing with other systems, with the overarching goal to continuously increase specified Enterprise Value.

The new system would replace a number of stand-alone, manual or semi-automated project management systems with inadequate monitoring of progress and productivity.

A thorough analysis of contemporary practices showed that such a transformation had never before been achieved. To the best of the team's knowledge, there were no real-time project management systems in existence anywhere in the world.

Challenges

This particular undertaking had a number of challenges.

The most important challenge was the resistance to change by client's managers. The new system with its progress and productivity monitoring capabilities threatened to expose inefficiencies and was not universally welcomed. Two approaches were planned to manage this challenge: the first was education of participants and the second, a proposal for a new payment structure which related salaries to meeting of targets, as reported by the new system.

The scale of the proposed network of systems was an even more important challenge, especially because all projects were mission critical. To manage this challenge, the plan was made to adopt an evolutionary development strategy. The first step was planned to be a fully engineered prototype with a limited functionality, which would be extended into the first project management system only after a complete acceptance by the client that the prototype was capable of delivering its limited functionality as specified. The network of project management systems would be grown step by step.

The multi-agent technology, which underpinned the system, was well understood by the team, and a methodology for managing complexity (Rzevski and Skobelev, 2014) of the task was in place.

Systems Engineering Practices

Overview

The complexity of client's projects ruled out all conventional project management practices and systems. Instead, for every project, the team designed a complex adaptive project management system, based on multi-agent technology, capable of meeting client requirements.

The system consisted of the following major components (Rzevski and Skobelev, 2014):

1. Knowledge Base containing domain knowledge relevant to the client's project management processes
2. Multi-agent Virtual World which models the Real World of projects and is capable of managing real-world complexity
3. Interfaces between the Virtual and Real Worlds, which enable the Virtual World to, in-effect, manage the Real World, with or without human intervention

Knowledge Base

Examples of Classes of Objects in the ontology are: Enterprise, Organizational Unit, Project, Task, Project Member (Human Resource), Hardware (Physical) Resource, Document, Software Resource, Knowledge Resource and Process.

Examples of attributes are, for Task: Content, Cost, Duration, Deadline and Preferences; and for Project Member: Organizational Unit, Competences, Profile, Schedule, Current Task, Salary, Achievements and Preferences.

A fragment of enterprise ontology is shown below.

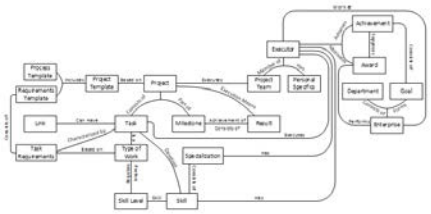

Figure. 1 A fragment of enterprise ontology. This material is reproduced with permission of G. Rzevski and publisher WitPress. All other rights are reserved by the copyright owner.

Virtual World

Examples of agents that populate the Virtual World include:

- Task Agent, whose objective is to search for the best resources capable to meet its requirements
- Human Resource Agent, whose objective is to get the best possible task, which will keep the project participant fully occupied, provide opportunities for bonuses and/or enable the participant to learn new skills or get new experience
- Physical Resource Agent, whose objective is to maximize resource utilization
- Project Agent, whose objective is to maximize Project Value
- Enterprise Agent, whose objective is to maximize Enterprise Value

All decisions are made through agent negotiations, as exemplified by the following process:

Task Agents send messages to Human Resource Agents with required competences inviting them to contribute to task fulfilments. Human Resource Agents that are available send their bids. Task Agents offer project participation to those Agents that sent the best bids. Bids are subject to negotiations between affected agents.

A new Task Agent is created whenever a new task is formulated or a previously allocated task is modified. The new Task Agent consults ontology to find out what its objectives are and how to achieve them, and proceeds to send messages to selected Human Resource Agents inviting them to bid for project participation. It is very likely that this invitation will result in re-scheduling, giving an opportunity to Human Resource Agents that were not fully satisfied with their previous allocations to improve their positions. Remuneration, including bonuses, if any, is calculated on the basis of project member participation and achieved results. Enterprise members may participate in several projects.

The allocation of physical, software and knowledge resources is done in an analogous manner. Advanced methods (Rzevski and Skobelev, 2014) have been employed to maximise effectiveness of agent negotiation, such as, virtual microeconomics, agent satisfaction, agent proactivity, enterprise agents, swarm cooperation, etc.

Decisions on allocation of resources to project tasks are made using multiple criteria, for example, decreases in completion time, increases in quality and reducing identified risks, as illustrated below.

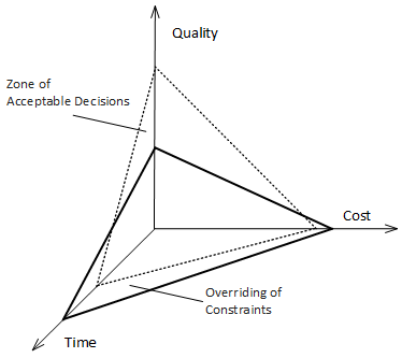

Figure 2. Decisions on allocation of resources to tasks are made using multiple criteria. This material is reproduced with permission of G. Rzevski and publisher WitPress. All other rights are reserved by the copyright owner.

Connecting Virtual and Real Worlds

The project member dashboard is the key link between the system and the project member. The exchange of information that could be conducted using the dashboard includes:

- Negotiations of task content, risks, deadlines and budgets
- Acceptance/rejection by the project member of offered project tasks
- Inputs by project members of unexpected disruptive events and comments during the project
- Reports by the system on the project member performance in carrying out accepted tasks

The system may decide to engage two or more available project members in competition with each other to secure an agreement on the acceptable task performance.

The other key link between the virtual and real worlds is the project managers dashboard, which displays detailed project performance data in the form of various diagrams and Gantt charts and allows the manager to examine or modify decisions made autonomously by the system.

Lessons Learned

The first real-time complex adaptive project management system was commissioned and deployed by the client in 2014 achieving the following results:

- 10% to 15% increase in project member productivity;
- 3 to 4 times reduction in manpower required for project scheduling, monitoring and coordination;
- 2 to 3 times reduction of response time to unpredictable disruptive events;
- 15% to 30% increase in the number of projects completion on budget and in time;
- A significant increase in project member motivation;
- A possibility to increase the number of projects operating in parallel without increasing the number of employees.

How Lack of Information Sharing Jeopardized the NASA/ESA Cassini/Huygens Mission to Saturn

- Lead Author:
- Brian White

-

This article describes a deep space mission where more forthright information exchanges between teamed but rival agencies could have both preserved the original plan and saved much time and money. The topic may be of particular interest to those involved in institutional collaborations where there are vested interests in protecting rather than sharing information.

For additional information, refer to the closely related topics of Information Management, Organizing Business and Enterprises to Perform Systems Engineering and Fundamentals of Services.

Background

Before the “Faster, Better, Cheaper” philosophy introduced in the 1990s, the United States National Aeronautics and Space Administration (NASA) focused on three classes of unmanned space missions. In order of increasing cost, these were the Discovery, New Frontiers, and Flagship programs. Flagship programs typically cost more than $1B, and included the Voyager (outer planets), Galileo (Jupiter), Cassini-Huygens (Saturn), Mars Science Laboratory (Mars), and the James Webb Space Telescope. (Wall 2012)

The concept of the Cassini-Huygens mission was initiated in 1982 as the result of a working group formed by the National Academy of Sciences and the European Science Foundation. This group sought opportunities for joint space missions; several subsequent reports endorsed the working group’s concept of a Saturn orbiter coupled with a Titan (Saturn’s largest moon) lander. (Russell 2003, p. 61.)

By 1988, NASA was politically motivated to reverse earlier tensions with the European Space Agency (ESA) by engaging in a joint mission. Cassini-Huygens was seen as a mechanism to achieve this goal, and the cooperation between NASA and ESA helped the program survive potential budget cuts (since the U.S. was obligated to match ESA commitments). (Russell 2003, p. 62.)

NASA and ESA approved the Cassini-Huygens program, and it proceeded under a traditional management approach. NASA built the Cassini orbiter (the largest and most complex unmanned space probe ever built) and the ESA constructed the Huygens lander. This partition of responsibility almost led to the failure of the Titan survey portion of the mission. Cassini (which would conduct a variety of scientific surveys of the Saturn planetary system) was expected to relay transmissions from Huygens to NASA's Deep Space Network (DSN); however, the interface between the lander and orbiter was not well-managed and erroneous assumptions about how the orbiter/lander system would behave after separation nearly doomed the Titan exploration portion of the mission. (Oberg 2004.)

Purpose

The intent of the Titan survey portion of the Cassini-Huygens mission was that the Huygens lander would separate from the Cassini orbiter and commence a one-way, 2.5 hour descent into Titan's atmosphere. Its modest transmitter would send data back to the orbiter, which would relay the information to Earth. (Oberg 2004, p. 30.) This effectively made the radio link between the two spacecraft a poorly-characterized single point of failure (SPOF).

Alenia Spazio SpA, the Italian communications vendor that built the radio system, overlooked the Doppler shift (approximately 38 kHz) (Oberg, 2004, p. 31) that would occur when Huygens separated from Cassini and began its descent (Oberg 2004, p. 38). The communications protocol was binary phase-key shifting: "[the] transmission system represents 1s and 0s by varying the phase of the outgoing carrier wave. Recovering these bits requires precise timing: in simple terms, Cassini's receiver is designed to break the incoming signal into 8192 chunks every second. It determines the phase of each chunk compared with an unmodulated wave and outputs a 0 or a 1 accordingly". (Oberg 2004, p. 31.) The receiver was appropriately configured to compensate for the Doppler shift of the carrier wave but would be unable to adjust for the Doppler shift of the encoded data. "In effect, the shift would push the signal out of synch with the timing scheme used to recover data from the phase-modulated carrier." (Oberg 2004, p. 33) Therefore, the communications system would be unable to decode the data from the lander and would then relay scrambled information to NASA. Because of the failure mechanism involved, the data would be completely unrecoverable.

Both Cassini and Huygens had been tested before launch; however, none of the testing accurately reflected the Doppler shift that would be experienced at this critical phase of the mission. An opportunity to conduct a full-scale, high-fidelity radio test was ignored due to budget constraints; the testing would have required disassembly and subsequent recertification of the probes. (Oberg, 2004, p. 30.) Correcting this latent issue via a minor firmware upgrade would have been trivial before the spacecraft were launched (Oberg 2004, p. 33) once they were on the way to Saturn any corrective action would be severely limited and expensive.

Once the mission was underway, the probe coasted along its seven-year trajectory to Saturn and its moons. Claudio Sollazzo, the ESA ground operations manager, was uncomfortable with the untested communications system. He tasked Boris Smeds, an engineer with radio and telemetry experience, with finding a way to test the communications system using an Earth-generated signal. (Oberg 2004, p. 30.)

Smeds spent six months developing the test protocols that would use Jet Propulsion Laboratory (JPL) ground stations and an exact duplicate of Huygens. Simulated telemetry would be broadcast from Earth to Cassini and relayed back; the test signal would vary in power level and Doppler shift to fully exercise the communications link and accurately reflect the anticipated parameters during Huygens's descent into Titan's atmosphere. (ESA 2005)

Challenges

Smeds faced opposition to his test plans from those who felt it was unnecessary, but ultimately prevailed due to support from Sollazzo and Jean-Pierre Lebreton, the Huygens project scientist. More than two years after the mission was launched, Smeds traveled to a DSN site in California to conduct the test. (Oberg 2004, p. 31)

A test signal was broadcast, received by Cassini, re-transmitted to the DSN site, and relayed to ESA's European Space Operation Centre (ESOC) in Darmstadt, Germany for analysis. Testing had to be conducted when the orbiter was in the correct relative position in the sky; it was more than a quarter of a million miles away with a signal round-trip time of nearly an hour. The test immediately exposed an issue; the data stream was intermittently corrupted, with failures not correlated to the power level of the test signal. The first of two days of testing concluded with no clear root cause identified. (Oberg 2004, p. 31.)

Even though the probe was far from its ultimate destination, many science teams were competing for time to communicate with it using the limited bandwidth available. The communications team would not be able to conduct another set of trials for several months. Smeds diagnosed the root cause of the problem; he felt it was the Doppler shifts induced in the simulated signal. However, the test plan did not include unshifted telemetry (an ironic oversight). He modified his test plan overnight and shortened the planned tests by 60%; this recovered sufficient time for him to inject an unshifted signal into the test protocols. (Oberg 2004, p. 32)

This unshifted signal did not suffer from the same degradation; however, other engineers resisted the diagnosis of the problem. Follow-up testing using probe mockups and other equipment ultimately convinced the ESA of the issue; this took an additional seven months. (Oberg 2004, p. 33.)

By late 2000, ESA informed NASA of the latent failure of the communications link between Cassini and Huygens. Inquiry boards confirmed that Alenia Spazio had reused timing features of a communications system used on Earth-orbiting satellites (which did not have to compensate for Doppler shifts of this magnitude). (Oberg, 2004, p. 33.) In addition, because NASA was considered a competitor, full specifications for the communications modules were not shared with JPL. The implementation of the communications protocols was in the system's firmware; trivial to correct before launch, impossible to correct after. (ESA 2005.)

A 40-man Huygens Recovery Task Force (HRTF) was created in early 2001 to investigate potential mitigation actions. Analysis showed that no amount of modification to the signal would prevent degradation; the team ultimately proposed changing the trajectory of Cassini to reduce the Doppler shift. (ESA 2005) Multiple studies were conducted to verify the efficacy of this remedy, and it ultimately allowed the mission to successfully complete the Titan survey.

Systems Engineering Practices

Space missions are particularly challenging; once the spacecraft is en route to its destination, it is completely isolated. No additional resources can be provided and repair (particularly for unmanned missions) can be impossible. Apollo 13's crew managed to barely survive the notable mishap on its mission because of the resources of the docked Lunar Excursion Module (LEM) and the resourcefulness of the ground control team's experts. A less well-known failure occurred during the Galileo mission to Jupiter. After the Challenger disaster, NASA adopted safety standards that restricted the size of boosters carried in the Space Shuttle. (Renzetti 1995.) Galileo was delayed while the Shuttles were grounded and Galileo's trajectory was re-planned to include a Venus fly-by to accelerate and compensate for a smaller booster. Galileo's main antenna failed to deploy; lubricant had evaporated during the extended unplanned storage (Evans 2003) and limited computer space led to the deletion of the antenna motor-reversing software to make room for thermal protection routines. When the antenna partially deployed, it was stuck in place with no way to re-furl and redeploy it. Engineers ultimately used an onboard tape recorder, revised transmission protocols, the available low-gain antenna, and ground-based upgrades to the DSN to save the mission. (Taylor, Cheung, and Seo 2002.)

The Titan survey was ultimately successful because simulation techniques were able to verify the planned trajectory modifications and sufficient reaction mass was available to complete the necessary maneuvers. In addition, Smeds's analysis gave the mission team the time it needed to fully diagnose the problem and develop and implement the remedy. If this test were conducted the day before the survey, it would merely have given NASA and ESA advance warning of a disaster. The time provided enabled the mission planners to craft a trajectory that resolved the communication issue and then blended back into the original mission profile to preserve the balance of the Saturn fly-bys planned for Cassini. (Oberg 2004, p. 33.)

Lessons Learned

The near-failure of the Cassini-Huygens survey of Titan was averted because a handful of dedicated systems engineers fought for and conducted relevant testing, exposed a latent defect, and did so early enough in the mission to allow for a recovery plan to be developed and executed. Root causes of the issue included politically-driven partitioning, poor interface management, overlooked contextual information, and a lack of appreciation for single-points-of-failure (SPOFs).

The desire to use a joint space mission as a mechanism for bringing NASA and ESA closer together (with the associated positive impact in foreign relations) introduced an unnecessary interface into the system. Interfaces must always be managed carefully; interfaces between organizations (particularly those that cross organizational or political borders) require extra effort and attention. Boeing and Airbus experienced similar issues during the development of the Boeing 787 and A380; international interfaces in the design activities and supply chains led to issues:

> *…every interface in nature has a surface energy. Creating a new surface (e.g., by cutting a block of steel into two pieces) consumes energy that is then bound up in that surface (or interface). Interfaces in human systems (or organizations), a critical aspect of complex systems such as these, also have costs in the effort to create and maintain them. Second, friction reduces performance. Carl von Clausewitz, the noted military strategist, defined friction as the disparity between the ideal performance of units, organizations, or systems, and their actual performance in real-world scenarios. One of the primary causes of friction is ambiguous or unclear information. Partitioning any system introduces friction at the interface.* (Vinarcik 2014, p. 697)

Alenia Spazio SpA's unclear understanding of the Doppler shift introduced by the planned relative trajectories of Huygens and Cassini during the Titan survey led it to reuse a component from Earth-orbiting satellites. Because it considered NASA a competitor and cloaked details of the communications system behind a veil of propriety, it prevented detection of this flaw in the design phase. (Oberg 2004, p. 33)

Because NASA and ESA did not identify this communication link as a critical SPOF, they both sacrificed pre-launch testing on the altar of expediency and cost-savings. This prevented detection and correction of the flaw before the mission was dispatched to Saturn. The resource cost of the later analysis and remedial action was non-trivial and if sufficient time and reaction mass had not been available the mission would have been compromised. It should be noted that a number of recent spacecraft failures are directly attributable to SPOFs (notably, the Mars Polar Lander (JPL 2000) and the Genesis sample return mission (GENESIS, 2005)). Effective SPOF detection and remediation must be a priority for any product development effort. More generally, early in the development process, significant emphasis should be placed on analyses focused on what might go wrong ("rainy day scenarios") in addition to what is expected to go right ("sunny day scenarios").

The success of the Huygens survey of Titan was built upon the foundation established by Boris Smeds by identifying the root cause of the design flaws in a critical communications link. This case study underscores the need for clear contextual understanding, robust interface management, representative testing, and proper characterization and management of SPOFs.

-

This article describes a remarkable engineering feat with vast scientific benefits and implications. The topic may be of particular interest to those facing formidable systems engineering challenges where one might thrive on a thoughtful blend of humility and optimism. For additional information, refer to the links provided in Section V: Lessons Learned below.

Background

The Hubble Space Telescope (HST) Case Study was developed by the United States Air Force Center for Systems Engineering (AF CSE) located at the Air Force Institute of Technology (AFIT). The AF CSE was tasked to develop case studies focusing on the application of systems engineering principle s within various aerospace program s. The HST study (Mattice 2005) is one of four initial case studies selected by AFIT for development in support of systems engineering graduate school instruction. The cases are structured using the Friedman-Sage framework (Friedman and Sage 2003; Friedman and Sage 2004, 84-96), which decomposes a case into contractor, government, and shared responsibilities in the following nine concept areas: STOPPED HERE

1. Requirements Definition and Management
2. Systems Architecture Development
3. System/Subsystem Design
4. Verification/Validation
5. Risk Management
6. Systems Integration and Interfaces
7. Life Cycle Support
8. Deployment and Post Deployment
9. System and Program Management

The case study provides a useful example of the rising cost of defect correction through successive life cycle phases, demonstrating how an error (in test fixture specification) that could have been fixed for $1,000 at the design stage, or detected and fixed with a $10 million investment in an end-to-end test of the telescope on the ground, ended up costing $1 billion to fix when the system was in service.

Purpose

The Hubble Space Telescope (HST) is an orbiting astronomical observatory operating in the spectrum from the near-infrared into the ultraviolet. Launched in 1990 and still operational, HST carries and has carried a wide variety of instruments producing imaging, spectrographic, astrometric, and photometric data through both pointed and parallel observing programs. Over 100,000 observations of more than 20,000 targets have been produced for retrieval. The telescope is well known as a marvel of science. This case study hopes to represent the facet of the HST that is a marvel of systems engineering, which, in fact, generated the scientific research and observation capabilities now appreciated worldwide.

Viewed with the clarity that only time and hindsight provide, the HST program certainly represents one of the most successful modern human endeavors on any scale of international scope and complex ity. As a systems engineering

project the HST had to respond to requirement s from the diverse international scientific community at a time when NASA was implementing a different research-development-acquisition philosophy and process than what was predominately being used in most major government acquisition programs. As with most other large programs, powerful influences outside the systems engineering process itself became issues that HST systems engineer s in effect had to acknowledge as integral to their overall system/program/engineering management responsibility.

Challenges

The story of how this remarkable capability came to be is a story of the complicated interactions of a systems engineering process, which we like to believe we understand, with equally demanding political, budgetary, and institutional processes we often fail to understand or comprehend at the time they occur. In the final analysis, these processes are inseparable and integral to attaining program success. The challenge to modern systems engineers is to fully embrace the discipline of the systems engineering process while at the same time learning how to continue to practice it in spite of inevitable external influences and instabilities that often cannot be anticipated.

Major differences revolved around the nature and needs of a very different HST “customer” or user from most DoD systems. The HST had to respond to requirements from the diverse international scientific community instead of from DoD’s combatant commands. In addition, at the time, NASA implemented a different research-development-acquisition philosophy and process than the DoD Acquisition Management Framework described in the DoD 5000 series acquisition reforms. As with most other large programs, powerful influences outside the systems engineering process itself became issues that HST systems engineers in effect had to acknowledge as integral to their overall system/program/engineering management responsibility.

Systems Engineering Practices

During the critical systems engineering phase for the HST program (1970s concept studies thru 1990 launch) there appears to have been no NASA systems engineering master process. Rather, field center processes were operative and possibly even in competition, as centers (especially Marshall and Goddard for HST) were in keen competition for lead management roles and responsibilities. We will see the systems engineering and program management impacts of this competition as it played out for HST, with the science mission objectives and instrumentation payloads being the motivation for Goddard vs. the vehicle/payload access to space motivation of Marshall. In the final analysis, the roles of the major contractors in engineering the system with uneven NASA participation over the system life cycle had a telling effect.

Lessons Learned

Five learning principles (LPs) were derived that address the more broadly applicable areas of systems engineering knowledge. These five LPs inform the areas of the SEBoK that are most strongly related to the case study. The five areas are:

- stakeholder requirements definition (LP1);
- planning (pre-program trade studies) (LP2);
- system integration (LP3);
- life cycle model management (LP4); and
- risk management (LP5).

A synopsis of the HST Learning Principles (LPs) are as follows:

Stakeholder Requirements Definition LP1: Early and full participation by the customer/user throughout the program is essential to success. In the early stages of the HST program, the mechanism for involving the customer was not well defined. The user community was initially polarized and not effectively engaged in program definition and advocacy. This eventually changed for the better, albeit driven heavily by external political and related national

program initiatives. Ultimately, institutionalization of the user's process for involvement ensured powerful representation and a fundamental stake and role in both establishing and managing program requirements. Over time, the effectiveness of "The Institute" led to equally effective user involvement in the deployment and on-orbit operations of the system as well.

Planning LP 2: The use of Pre-Program Trade Studies (e.g. "Phased Studies" or "Phased Project Planning") to broadly explore technical concepts and alternatives is essential and provides for a healthy variety of inputs from a variety of contractors and government (NASA) centers. These activities cover a range of feasibility, conceptual, alternative and preliminary design trades, with cost initially a minor (later a major) factor. In the case of HST, several NASA Headquarters and Center organizations funded these studies and sponsored technical workshops for HST concepts. This approach can promote healthy or unhealthy competition, especially when roles and responsibilities within and between the participating management centers have not yet been decided and competing external organizations use these studies to further both technical and political agendas. NASA Center roles and missions can also be at stake depending on political and or budgetary realities. The systems engineering challenge at this stage is to "keep it technical, stupid!"

Systems Integration LP 3: A high degree of systems integration to assemble, test, deploy, and operate the system is essential to success and must be identified as a fundamental program resource need as part of the program baseline. For HST, the early wedding of the program to the Shuttle, prior NASA and NASA contractor experience with similarly complex programs, such as Apollo, and the early requirement for manned, on-orbit servicing made it hard not to recognize this was a big systems engineering integration challenge. Nonetheless, collaboration between government engineers, contractor engineers, as well as customers, must be well defined and exercised early on to overcome inevitable integration challenges and unforeseen events.

Life Cycle Models LP 4: Life Cycle Support planning and execution must be integral from day one, including concept and design phases. The results will speak for themselves. Programs structured with real life cycle performance as a design driver will be capable of performing in-service better, and will be capable of dealing with unforeseen events (even usage in unanticipated missions). HST probably represents a benchmark for building in system sustainment (reliability, maintainability, provision for technology upgrade, built-in redundancy, etc.), while providing for human execution of functions (planned and unplanned) critical to servicing missions. With four successful service missions complete, including one initially not planned (the primary mirror repair), the benefits of design-for-sustainment, or life cycle support, throughout all phases of the program become quite evident. Without this design approach, it is unlikely that the unanticipated, unplanned mirror repair could even have been attempted, let alone been totally successful.

Risk Management LP 5: For complex programs, the number of stakeholders (government and contractor) demands that the program be structured to cope with high risk factors in many management and technical areas simultaneously. The HST program relied heavily on the contractors (especially Lockheed Missiles and Space Company (LMSC) and Perkin-Elmer (P-E)), each of which "owned" very significant and unique program risk areas. In the critical area of optical systems, NASA depended on LMSC as the overall integrator to manage risk in an area where P-E was clearly the technical expert. Accordingly, NASA relied on LMSC and LMSC relied on P-E with insufficient checks, oversight, and independence of the quality assurance function throughout. While most other risk areas were no doubt managed effectively, lapses here led directly to the HST's going to orbit with the primary mirror defect undetected, in spite of substantial evidence that could have been used to prevent this.

Applying a Model-Based Approach to Support Requirements Analysis on the Thirty-Meter Telescope

-

This article describes how a model-based systems engineering (MBSE) approach was used to support requirements analysis, system design, and early verification for critical subsystems of the Thirty Meter Telescope (TMT) [8]. The MBSE approach applied the Executable Systems Engineering Method (ESEM) [4] [5] and the Open-source Engineering Environment (OpenMBEE) [7] to specify, analyze, and verify requirements of TMT's Alignment and Phasing System (APS) and the Narrow Field Infrared Adaptive Optics System (NFIRAOS). The value proposition for applying this MBSE approach was to establish precise requirements and fine-grained traceability to system designs, and to verify key requirements using executable SysML [6] models beginning early in development.

Background

The TMT (Figure 1) is a next-generation ground-based extremely large telescope designed to answer key science questions regarding the nature and composition of the Universe. At its core is a wide-field, altitude-azimuth Ritchey-Chrétien design with a 492 segment, 30-meter diameter primary mirror (M1), a fully active secondary mirror, and an articulated tertiary mirror. Each segment's optical performance is sensitive to three rigid body degrees of freedom: piston, tip, and tilt. To obtain optimal image quality, the segmented M1 must perform like a single monolithic mirror, achieved through a multitude of controls working to co-align, co-focus, and co-phase its segments. The APS (Figure 2) is responsible for the overall pre-adaptive optics wavefront quality, using starlight to measure wavefront errors and align the TMT optics. Adaptive optics systems like the NFIRAOS (Figure 2) are designed to sense real-time atmospheric turbulence and correct the telescope's optical beam to remove its effect, enabling diffraction-limited imaging on the ground. In LGS MCAO and NGSAO modes, this is achieved through the use of wavefront sensors to detect laser and natural guide stars and deformable mirrors to direct the corrected wavefront to science instruments. These opto-mechanical designs and complex controls are constrained by several

requirements that must be satisfied.

TMT International Observatory (TIO), LLC is a non-profit organization of international members, responsible for managing the design, development, and operations of the TMT. The Jet Propulsion Laboratory (JPL) [9] participates in the design and development of several TMT subsystems and delivers an operational APS, where TIO is responsible for providing requirements to JPL. The APS team applies an MBSE approach to analyze requirements, derive an architecture design, and implement a system. TIO also works with JPL to analyze the operational behavior of NFIRAOS through modeling system-level operational scenarios (such as slew, acquisition, and dithering) with Monte-Carlo simulations. Modeling patterns are used to capture functional and physical system characteristics, behavior, requirements, parametric relationships, and use case scenarios. MBSE applications are motivated by optimization to better understand TMT's complex system behaviors.

Purpose

This article describes how MBSE is applied to the development of critical subsystems of a complex interdisciplinary system and the benefits of this approach. While document-based artifacts are necessary throughout the development lifecycle, complex systems engineering relies significantly on the use of models to address concerns from various domains (e.g. mechanics, optics, controls) (Figure 3). MBSE helps to manage implicit dependencies on information contained in these cross-domain documents, understand change impacts, analyze designs, and communicate evolving technical baselines. Models act as the single source of authority for systems engineering information that enables optimization through consistent and automated data exchange, enhanced analyses, and consolidating subsystem design information into separate artifacts needed by various stakeholders.

MBSE Challenges

Systems engineering (SE) is inherently challenging with concepts spanning several engineering disciplines. Expressing these concepts in a model demands the use of flexible methodology, language, and tools. The modeler must understand how to leverage this flexibility to rigorously specify systems with a broad range of complex design considerations. This poses the initial MBSE challenge—**the learning curve**. However, this challenge is native to any new undertaking and is overcome by hands-on experience, training, and ever-growing resources.

Another challenge is determining how to **apply** MBSE to meet the needs of a project. MBSE is not separate from SE—it is an approach to achieve the fundamental goals of SE more efficiently. MBSE should not be used to duplicate work, but instead replace efforts that can be better accomplished formally through modeling.

Engineers live in a landscape of variability among tools and information models in different domains (e.g. ALM, PLM, CAD), which are often implicitly connected [4]. To benefit from a model-based paradigm, the models require explicit connections. A key challenge is how to leverage data and associated models to enable **cross-domain integration**.

Finally, **standardization** is a challenge for MBSE. A model is only effective if stakeholders can understand it. SysML is an evolving modeling language that is becoming the dominant standard to communicate system architectures, independent of the modeling tools that use it. However, SysML is only one of many standards that must be applied to ensure the models can be consistently interpreted by tools and users.

MBSE Approach

The MBSE approach follows the conventional SE V-process enriched by a model-based paradigm (Figure 4). The scope of this MBSE application addresses models at L2 and L3, and requirements flow-down to L4, although the approach can be applied to support specification and architecture design at other levels as well. Associated modeling artifacts are created early and maintained throughout the development lifecycle.

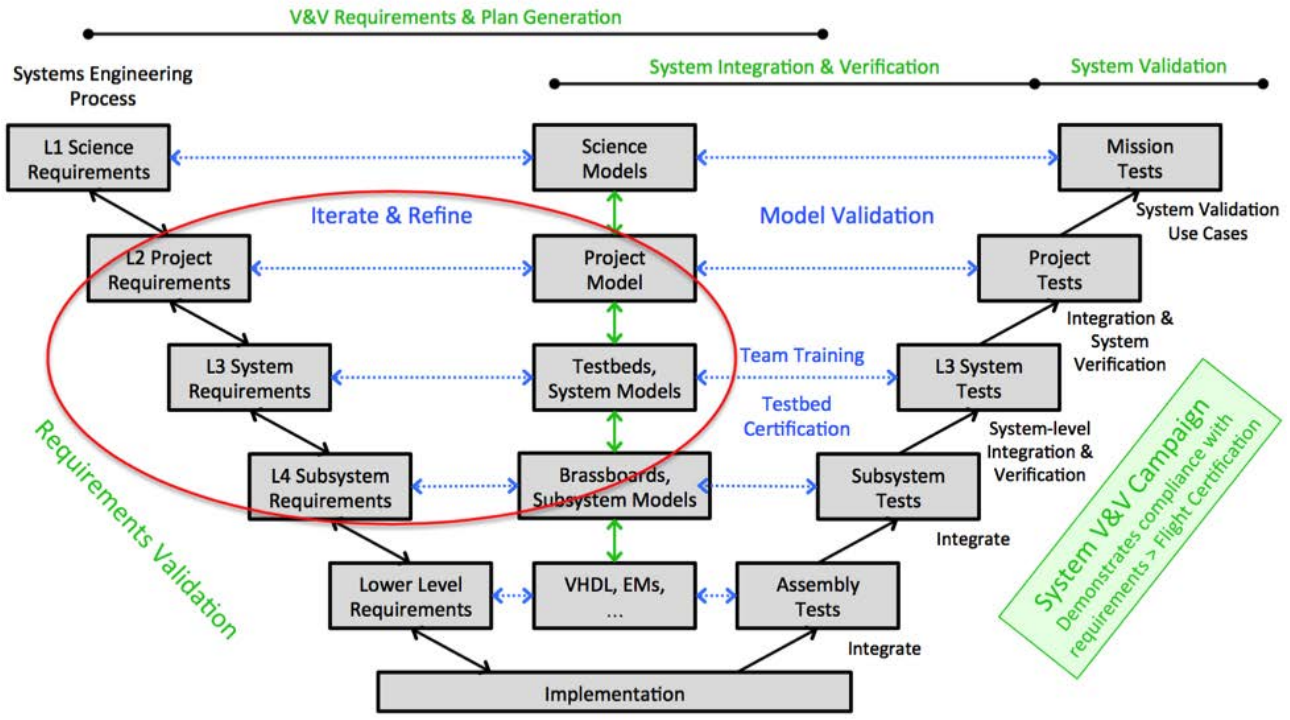

Figure 4. JPL Model-based V Process. (Used with permission. Permission granted by Jamie Nakawatase.)

MBSE articulates the system architecture in a formal, executable model that captures structure, behavior, requirements, and parametric relationships of system elements. Operational scenarios are defined in the model and analyzed through system-level simulation to verify requirements and validate overall system design over an expected range of conditions and parameters. The system model is also the authoritative source for several engineering documents. The MBSE approach is subsequently described by its methodology, tooling infrastructure, and analysis processes.

Methodology

The Executable Systems Engineering Method (ESEM) [1] is used to formalize requirements, specify system designs, characterize components, and specify/run analyses. ESEM augments the Object Oriented Systems Engineering Method (OOSEM) [2] by enabling executable models that enhance understanding, precision, and verification of requirements through applying analysis patterns specified with various SysML diagrams. ESEM also enables integration of supplier/customer models.

Figure 5 shows the major activities common to SE processes using OOSEM. The red circles indicate where ESEM injects formal modeling methods.

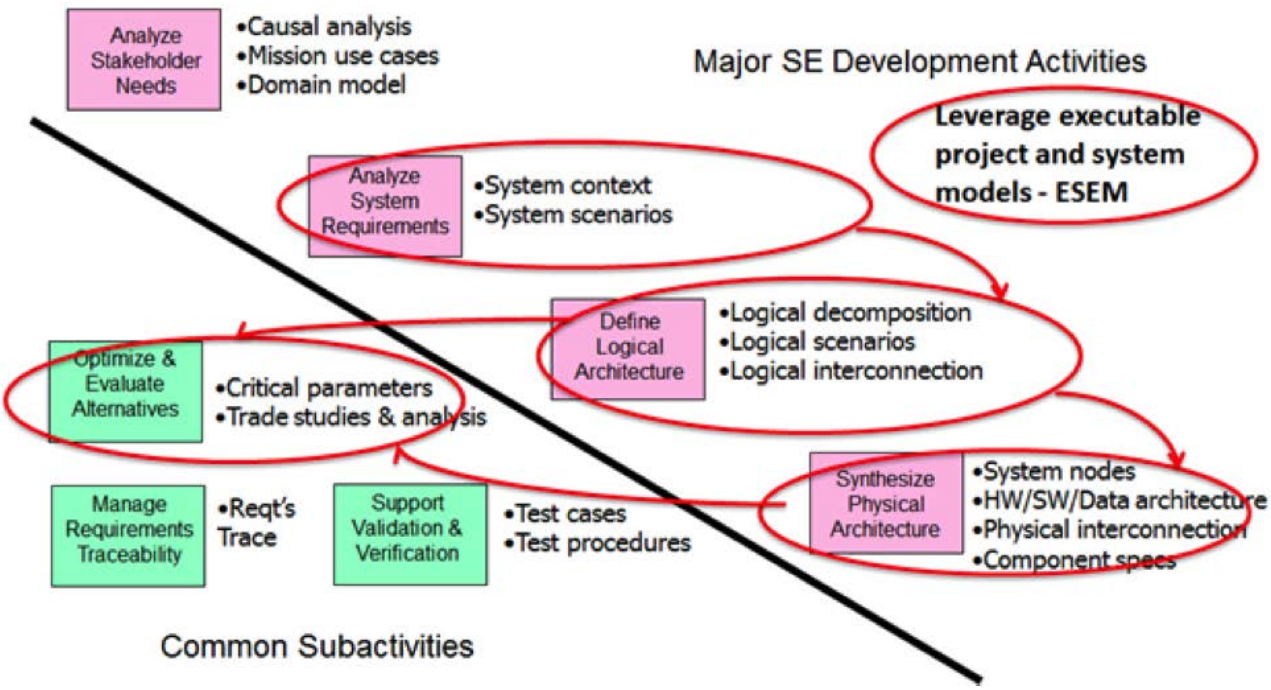

Figure 5. OOSEM activities. (Used with permission. Permission granted by Jamie Nakawatase.) [8]

ESEM is utilized to model different levels of abstraction that are analyzed using several modeling patterns as detailed in [4]. The system-of-interest is modeled as a black box that interacts with external subsystems, such as controls. Interactions are modeled using ports to identify operations and flows at the system-of-interest interface.

The conceptual model specifies technology-independent system components and captures their behavior. This part of the model is used to analyze characteristics such as duration of operational scenarios. Component behavior is captured using state machines and activity diagrams, and constraint parameters are captured in a table. Communication across internal and external system components is accomplished through the sending and receiving of signals through ports. This model supports production of interface control documents by querying information sent from one component to another over ports.

The conceptual model serves as a basis to specify the realization model of the physical components. The realization model imposes technology-dependent constraints on the design solutions. Both the conceptual (i.e. logical) and realization (i.e. physical) models represent the “as-specified” system.

Tooling

The MBSE approach uses standard SysML language and modeling tools to minimize custom software. The OpenMBEE community promotes an open tooling environment that provides a platform for modeling. It utilizes the Model Management System (MMS) that can be accessed from rich SysML desktop clients like MagicDraw, lightweight web-based clients like View Editor, computational programs like Mathematica, and other tools that utilize RESTful web services. The MMS also provides the basic infrastructure for search, relation management, versioning, workflow, access control, content flexibility, web applications support, web-based API access, and multi-tool/repository integration across engineering and management disciplines.

Figure 6 shows the integration of model artifacts produced by MMS, View Editor, and MagicDraw. System models are constructed, queried, and rendered following the view and viewpoint paradigm [3] from MMS.

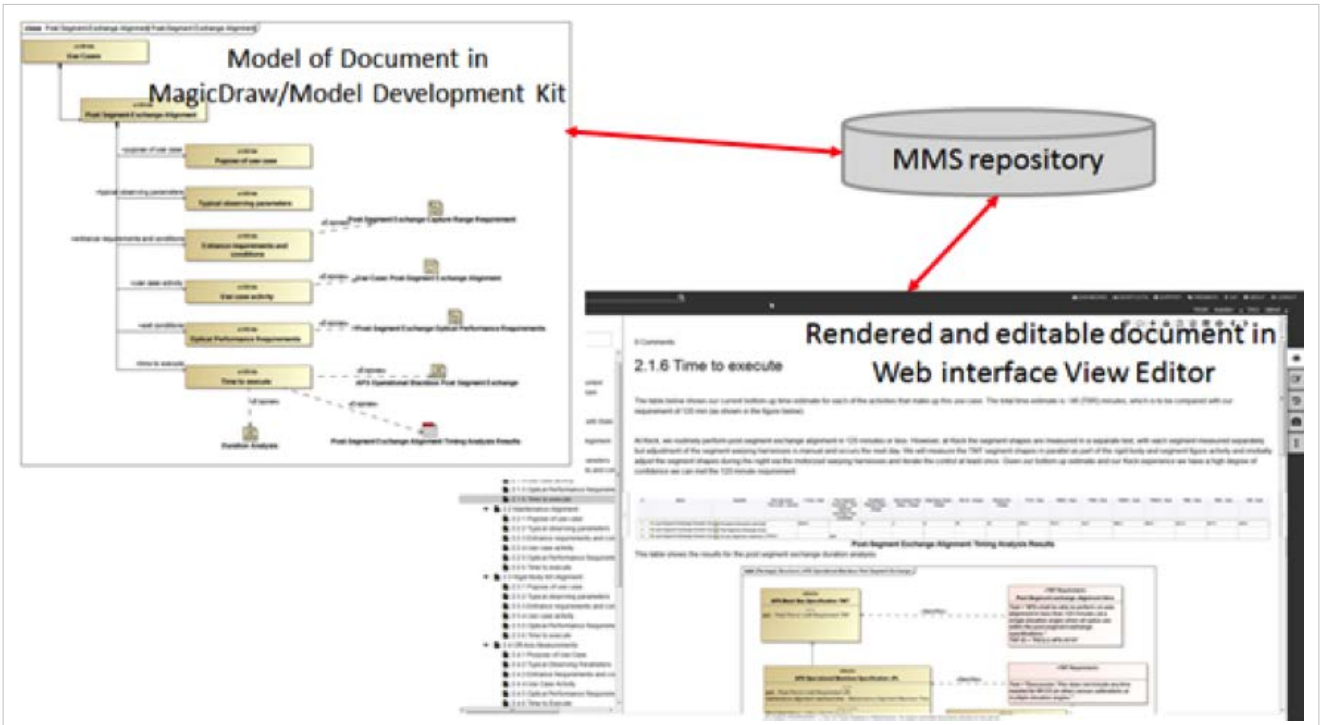

Figure 6. OpenMBEE interactions. (Used with permission. Permission granted by Jamie Nakawatase.)

Analysis

One key SE process is to analyze the impact of changing requirements on the system design. Figure 7 illustrates how the MBSE approach is used to support requirements impact analysis through the following steps:

- Step 1: A changed requirement triggers impact analysis.
- Step 2: MMS integrates DOORS (which manages text requirements) and the SysML model, enabling a DOORS requirement change to propagate to the SysML model.
- Step 3: A property-based requirement is formalized in SysML, enabling requirements specification that can be evaluated by engineering analysis.
- Steps 4-6: The conceptual and/or realization design is automatically verified against the changed requirement, resulting in pass or fail.

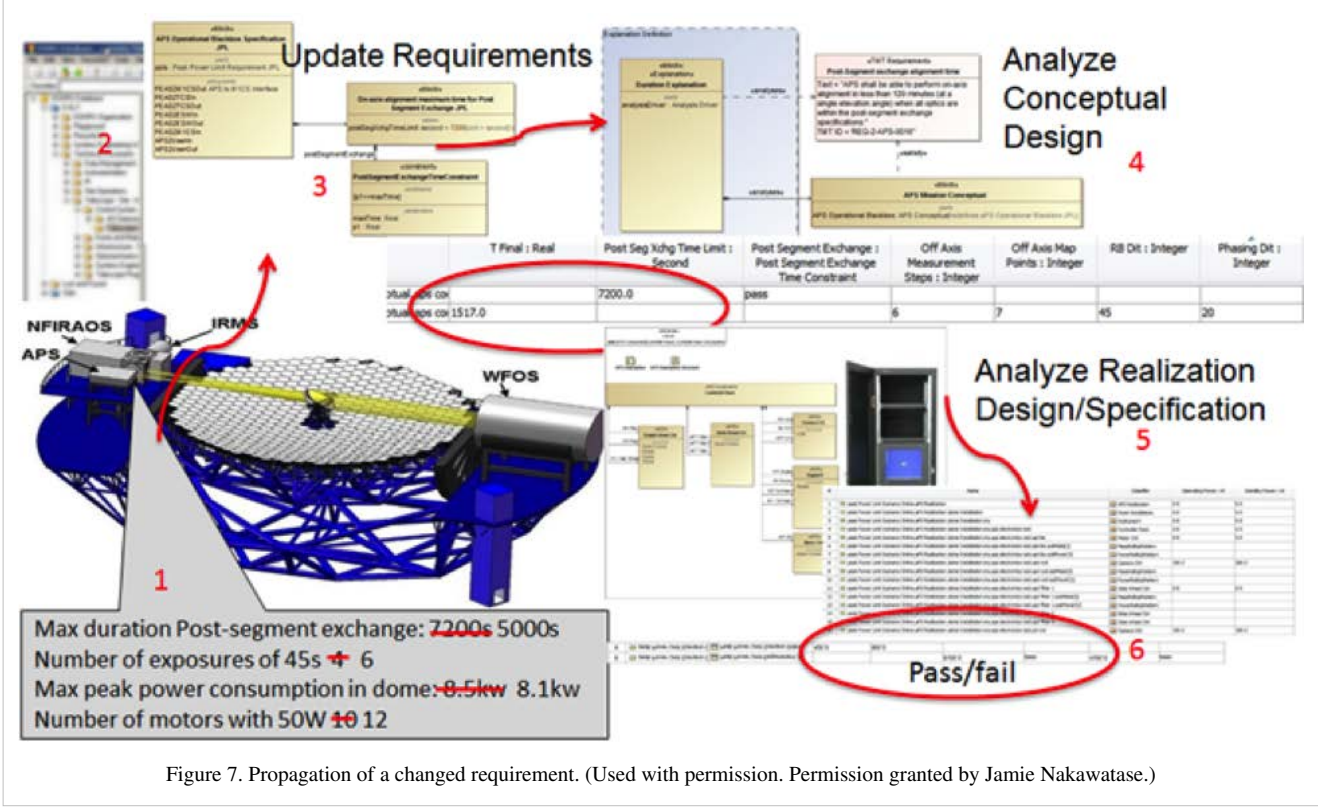

Figure 7. Propagation of a changed requirement. (Used with permission. Permission granted by Jamie Nakawatase.)

In this article, a simplified APS model is shown to illustrate the model-based approach for analyzing changed requirements. The full analysis is available in [4] and [5].

A model-based approach was also applied to APS for error analysis, which was performed to describe the accuracy of expected system performance against requirements. It involved multiple artifacts to analyze a requirement such as "APS shall measure the position of the telescope pupil to an accuracy of 0.03% of the diameter of the pupil." Defining requirements and parameters in the model indicated the required accuracy and current best estimates of the system design. Defining various roll-up patterns allowed for error decomposition calculations. The benefit is realized in automated requirements verification when applying a parametric solver to formulate results for specified equations in the model. This model-based approach formally integrates accuracy requirements with the system design.

The system model for NFIRAOS LGS MCAO and NGSAO modes was developed to capture sequence behaviors and operational scenarios to run Monte-Carlo simulations for verifying acquisition time, observing efficiency, and operational behavior requirements. The model is particularly useful for investigating the effect of parallelization, identifying interface issues, and re-ordering sequence acquisition tasks.

ESEM enables system analysis by conducting quantitative assessments to select and/or update the most efficient system architecture and generate derived engineering data. System analysis provides rigor for technical decision-making. It includes modeling and simulation, cost, technical risks, and effectiveness analyses, and is used to perform trade studies. In particular, it supports requirements verification, which assesses whether a system design meets its objectives and satisfies the constraints levied by system requirements.

Observed Benefits

The MBSE approach applied to APS and NFIRAOS was motivated by optimization to coordinate the efforts of complex system development. In these applications, implicit dependencies are made explicit in a formal model through the use of ESEM, OpenMBEE, and SysML modeling constructs. Requirements are formalized and tracked directly to the evolving system design. This tight association of requirements within a common environment promotes cross-domain integration and efficient communication among stakeholders. The model is used to automate requirements verification and to generate systems engineering products. The benefit over a traditional document-based approach is that currently disconnected artifacts become related in the model, enabling the production of consistent model-based documentation. Requirements verification is an important analysis conducted in the context of MBSE. To perform this analysis, the requirements, executable behavior, and models predicting the system's performance must be integrated. The ability to integrate these elements using ESEM and the OpenMBEE tooling infrastructure is a significant value proposition for the MBSE approach described in this article. In the formally integrated and executable SysML model, simulations are performed to analyze the impact of changed requirements and verify that requirements are met within specified constraints for various operational scenarios. MBSE enhances information exchange through created visualizations that communicate system behavior. For example, duration analyses were performed to study acquisition time for observing. The use of Monte-Carlo simulations proved how the model-based approach optimized the analysis process. Higher quality analysis results were obtained through the execution of operational scenario runs in an articulated system model, and the model continues to serve as a communication tool across various domains.

Miniature Seeker Technology Integration Spacecraft

- Lead Authors:
- Heidi Davidz, Art Pyster, and Deva Henry
- Contributing Author:
- Dave Olwell

-

The Miniature Seeker Technology Integration (MSTI) spacecraft was the first of its kind: a rapid development spacecraft, designed and launched in one year. As an aerospace example for a satellite application, the case study, "M.S.T.I.: Optimizing the Whole System" (Grenville, Kleiner, and Newcomb 2004), describes the project's systems engineering approach. Driven by an aggressive schedule, MSTI optimized over the whole project, rather than allowing sub-optimizations at the component level. As a partnership with Phillips Laboratories, the Jet Propulsion Laboratory (JPL), and Spectrum Astro, MSTI went into orbit on November 21, 1992. The MSTI-1 succeeded in meeting all primary mission objectives, surpassing the 6-day data collection mission requirement.

Domain Background

There are many case study examples for aerospace systems. This case is of particular interest because it highlights mechanisms which enabled successful performance following an aggressive schedule. Since this rapid development spacecraft was designed and launched in one year, new ways of structuring the project were necessary. Within this domain, the MSTI project used an innovative approach. Practices from this project led to the Mission Design Center and the System Test Bed at JPL.

Case Study Background

This case study was developed in support of the National Aeronautics and Space Administration (NASA) Program and Project Management Initiative by authors at the Virginia Polytechnic Institute and State University and Scientific Management, Inc. The case study was developed in the interest of continuously improving program and project management at NASA (NASA 2010). Research for this case included comprehensive literature review and detailed interviews. The project was selected based on the potential for providing lessons learned.

Case Study Description

The MSTI case study illustrates many principles described in the Systems Engineering Body of Knowledge (SEBoK). The MSTI team had to make adjustments to the traditional approach to spacecraft development in order to stay within budget and to meet the aggressive timeline of bringing a spacecraft from conception to launch within one year. The team realized that they were "building Porsches not Formula 1s"(Grenville, Kleiner, Newcomb 2004). Meeting the schedule was a crucial factor that affected all decisions. The SEBoK knowledge area on life cycle models describes life cycle design in more detail.

The team took advantage of existing hardware architectures for their architectural design to expedite the project. In addition, at each design phase, the whole system was optimized instead of optimizing subsystems, and the level of optimization at the subsystem level was reduced. A hardware-in-the-loop test bed was used throughout the project, which expedited system integration.

The schedule was maintained only at a high level in the project management office, and the costs were managed using a cost reporting technique for "cost to completion." Rather than report on past spending, the Responsible Engineering Authorities (REAs) were expected to continually evaluate their ability to complete their tasks within projected costs. Faster procurement was achieved using the Hardware Acquisition Team, where a technical team member was matched with a procurement representative for each design function. This pair wrote the specifications together and initiated the purchase requisitions.

From the organizational perspective, increased responsibility and accountability were given to each team member. Individuals took ownership of their work and the decision process was streamlined. The team made more "good decisions," rather than optimal decisions. The team was collocated, and daily meetings were used to assign daily tasks and keep the team focused on the launch. The standard Problem Failure Report (PFR) was streamlined and electronic reports provided snapshots of the resolved and outstanding PFRs. The report helped REAs stay on top of potential problem areas. REAs were responsible for looking forward on the project horizon and notifying the team of any potential problem areas.

The first satellite in the MSTI series, MSTI-1, was launched on November 21, 1992. The spacecraft weighed 150 kg and was built for $19M in less than 12 months. Over 200,000 photographs were returned from the spacecraft. From a project management standpoint, all mission objectives were completed.

In addition, MSTI had a lasting legacy. Faster procurement developed into an approach JPL now calls "Fast Track Procurement." Hardware acquisition teams are used often in JPL projects. The hardware-in-the-loop test bed was the precursor to the Flight System Test Bed at JPL. Team members moved up quickly in JPL due to the increased responsibility and authority they were given on the MSTI project.

Summary

MSTI demonstrated that an aggressive schedule can be used to design low earth-orbiting spacecraft to optimize the full system. The MSTI experience changed JPL's culture and their approach to spacecraft development and mission management. The insights from this case study example can help both students and practitioners better understand principles described in the SEBoK.

Apollo 1 Disaster

- Lead Authors:
- W. Clifton Baldwin and Anthony Long

-

On January 27, 1967, the crew of Apollo 204 was training for the first crewed Apollo flight, an Earth orbiting mission scheduled for launch on 21 February. Flight commander Gus Grissom, astronaut Edward White and astronaut Roger Chaffee died when fire swept the Apollo Command Module during this preflight test. After the accident, NASA reclassified Apollo 204 as Apollo 1. This case study examines some of the human factors shortfalls that lead to the Apollo 1 disaster.

Background

On January 27, 1967, the crew of Apollo 204 was training for the first crewed Apollo flight, an Earth orbiting mission scheduled for launch on 21 February. They were involved in a "plugs-out" test on the launch pad just as in the actual launch, except the rocket was not fueled. This test was a simulation, going through an entire countdown sequence. Flight commander Gus Grissom, astronaut Edward White and astronaut Roger Chaffee died when fire swept the Apollo Command Module during this preflight test. After the accident, NASA reclassified Apollo 204 as Apollo 1.

During the test and subsequent accident, emergency teams were not in attendance (Benson and Faherty 1978). The fire crews were only on standby since the vehicle was not fueled (Freiman and Schlager 1995). It was believed that the test did not rate a hazardous classification (Benson and Faherty 1978) (NASA History Office 1967), and the emergency equipment located in the launch tower test room was not designed for the type of fire that resulted (NASA History Office 1967). Within the capsule, there were no design features for fire protection as no one had considered the possibility of a fire from anything other than the rocket engines (NASA History Office 1967). There was not even a fire extinguisher in the cabin (Freiman and Schlager 1995) (Kranz 2000). Astronaut Frank Borman later stated, “None of us gave any serious consideration to a fire in the spacecraft” (Benson and Faherty 1978).

NASA leveraged technical knowledge from the two earlier Mercury and Gemini space programs and utilized their designs as a baseline for the Apollo program (Rosholt 1966). Naturally, some problems were expected from such a huge undertaking. Due in part to a multitude of integration issues, the crew could not escape the fire. After the accident, however, NASA officials admitted that they had concentrated their efforts on “in flight” situations and had not even considered problems on the ground (Benson and Faherty 1978) (Kranz 2000).

Challenges

During the late 1960s, NASA's systems integration group appeared to be largely paperwork focused, although NASA considered the Apollo 204 test as a type of systems integration test (Baldwin and Reilly 2005). Regardless of the systems integration efforts, there were obvious gaps integrating the astronauts leading to the unfortunate consequence of the deaths of the men of Apollo 1.

Integration of the Hatch

Designing and integrating safety into the space capsule was known to be an important factor from the start of the space program. The hatch was the primary means for the astronauts to enter and exit the capsule, and therefore it was a vital component for integrating the astronauts.

Both the Mercury and the Apollo capsules were equipped with a means for escaping from a launch-vehicle failure (Purser, Faget and Smith 1965) (Swenson Jr., Grimwood and Alexander 1998). This escape system consisted of a booster rocket on the capsule that could fly the capsule away from a malfunctioning rocket. The Gemini capsule had ejection seats instead. Due to the dangers during an emergency ejection, the Apollo design went back to an escape tower booster (Purser, Faget and Smith 1965). Without the ejection seats, the quick-opening hatches used by the Gemini program were not required. Initially, the Apollo capsule contractors North American Aviation had recommended a hatch that opens outward with explosive bolts for emergencies. NASA designers disagreed due to the accidental opening of an earlier Mercury capsule with a similar hatch design (Brooks, Grimwood and Swenson 1979). "NASA and North American designers hadn't been as worried about escape contingencies as they were about the possibility of a hatch popping open into the vacuum of space or another inadvertent opening during a water landing" (Kranz 2000).

In order to keep the astronauts safe, "An Apollo mission designer would prefer that the crew never exit the space capsule" (Mendell 1998). Therefore, the designers integrated the hatch to open inward, which allowed the internal pressure to assist in keeping the hatch secure (Murray and Cox 1989). The result of the integration process was a three-part hatch, an inner pressure hatch that opened inward when the capsule was on the ground, an ablative hatch that opened outward when in space, and a boost protective cover to protect the capsule during launch from the escape tower boosters (Freiman and Schlager 1995) (Kranz 2000) (NASA History Office 1967). Furthermore, the designers chose not to have an explosive hatch. As an aside to the Apollo 1 accident, even if the capsule had an explosive hatch, it would not have been armed during the test due to the danger to the support personnel (Murray and Cox 1989).

It took at least 90 seconds to open the hatch under ideal conditions (Freiman and Schlager 1995) (Senate Committee on Aeronautical and Space Sciences 1968). In practice, the crew had never accomplished the egress in the minimum time. Additionally, escaping was a very complicated procedure to perform under emergency circumstances. For example, it required one astronaut to lower another one's headrest in order to actuate a ratchet-type device that would release the first of a series of latches (NASA History Office 1967). When the accident occurred, it took five minutes and 25 seconds to open the hatch (NASA History Office 1967). The Apollo Review Board criticized this problem as well as obviously recommended it to be changed (Benson and Faherty 1978).

The accident of Apollo 1 caused NASA to reconsider its decisions and processes. Although well integrated technically, NASA was lacking in integrating the astronauts with the hatch. To remedy this problem, the hatch was redesigned to be single-hinged that could be unlatched in three seconds and would swing outward with minimal force (Benson and Faherty 1978).

Integration of the Environmental Control System

Perhaps the most complex of all the human factors elements concerned the Environmental Control System (ECS). This system was designed to control the quantity and quality of air delivered to the astronauts, maintain cabin pressure, and heat and cool the astronauts, equipment, and cabin. Extremes of space flight had to be anticipated and this system needed to meet the needs of that harsh environment. Redundancy was built in to provide suitable backup systems and ensure reliability and availability (NASA History Office 1967).

NASA engineers had performed trade studies that concluded a pure oxygen atmosphere in the cabin was preferred. Again, this decision failed to fully consider the astronauts. In 1964, Dr. Emmanuel Roth of the Lovelace Foundation for Medical Education and Research prepared for NASA a paper warning about the dangers of pure oxygen (Benson and Faherty 1978). Natural fabrics, most synthetics, and even allegedly flameproof materials will burn violently in a pure oxygen environment. In that same year, Dr. Frank J. Hendel, a staff scientist with Apollo Space Sciences and Systems at North American Aviation, wrote an article warning against pure oxygen especially on the launch pad (Benson and Faherty 1978). Joe Shea, head of Apollo Spacecraft Program Office at the time, wrote in a memo, "The problem is sticky- we think we have enough margin to keep fire from starting - if one ever does, we do have problems. Suitable extinguishing agents are not yet developed" (Murray and Cox 1989).

Due to the ongoing redesign and test environment in which the ECS was operated, there was a need to change out components quickly and easily to save time on the schedule (NASA History Office 1967). This need resulted in poor wiring placement as well as insulation (Stavnes and Hammoud 1994). Coolant coils were placed in locations that permitted them to be used as a handle to move about in the cabin. This unintended usage led to a leakage of coolant in the cabin, whereby the vapors were flammable and the coolant itself in liquid form was corrosive to the insulation of the nearly 12 miles of electrical wiring in the command module (Freiman and Schlager 1995) (NASA History Office 1967). The cooling system was extensive throughout the capsule, and coolant leakage at solder joints had already been a chronic problem (NASA History Office 1967).

One ECS cable was wedged against the bottom of a door used by the astronauts. When the door was shut, it would scrape the cable. The repeated abrasion eventually exposed two tiny sections of wire on the cable (Murray and Cox 1989). When the insulation became worn away, the wiring system would fail, and sparks could arc (Stavnes and Hammoud 1994). To make matters worse, flammable raschel netting near the scuffed cable was located closer to the cable than it should have been (Murray and Cox 1989).

The astronauts' spacesuits were also not incorporated well into the ECS. A suit-loop provided air quality control, temperature control, pressure control, humidity control, and decontamination to the astronauts and the cabin. There were three astronauts suited up and plugged into the loop with a fourth suit position. This so-called fourth suit position provided forced ventilation and exchange of the cabin air with the suit circuit (Bellcomm, Inc. 1964). This link of the spacesuits to the cabin could not be closed off in an emergency. The result would allow internal toxic gases from a fire to penetrate the astronauts' suits.

Integration of the Egress System

Until the accident, no one seriously considered the possibility of a safety issue within the capsule. The egress system, which would allow astronauts to get away from the launch pad, was not thoroughly explored and several integration problems were missed (NASA History Office 1967). "We all assumed that when a calamity struck, it would be in flight. Our nightmare was an explosion during launch, or a flying coffin, a faulty craft stuck in endless orbit" (Kranz 2000). There were no formal procedures for an in-capsule emergency on the ground for either the crew or the spacecraft pad work team (NASA History Office 1967).

The designers' experience necessitated "The use of an escape system should a malfunction occur during the powered ascent portion of the trajectory" (Purser, Faget and Smith 1965). Unfortunately, the designers only considered escape situations where the astronauts had to remain in the capsule. Hazard analysis was done to "Examine all the hazards that might require escape from the launch vehicle during powered flight" (Purser, Faget and Smith 1965).

Nonetheless, the hazards were thought to come through three operational phases, "1) liftoff and shortly thereafter, 2) transonic through maximum dynamic pressure regimes, and 3) shutdown and staging" (Purser, Faget and Smith 1965). There is no mention of a hazard within the capsule itself.

Additional evidence for unsatisfactory egress can be found in the launch pad environment. Even if they could get the hatch open, there were no contingency preparations to permit escape or rescue of the crew from an internal capsule fire. The umbilical tower access arm contained features such as steps, sliding doors and sharp turns in the egress paths that hindered emergency operations (NASA History Office 1967). Albeit too late for Apollo 1, the Apollo 204 Review Board sharply criticized the fact that the astronauts had no quick means of escaping the capsule (Benson and Faherty 1978).

Integration Lessons

Systems Thinking Approach

A systems approach to integration with respect to the capsule and rocket may have avoided overlooking the users' needs inside the capsule. For example, the ECS was designed without fully considering the astronauts onboard. Decisions to limit space in order to restrict subsystems from growing in weight were made by rule of thumb. A "whole system" integration approach could have arrived at a design for the ECS while considering the astronauts' needs. Early integration of the astronauts could have saved time, especially since those changes had to be made eventually, and would have saved lives. For more information, see Part 2, Overview of the Systems Approach.

Use Cases

NASA designers stated they considered three phases of operations which were known to be hazardous. A problem with their analysis is that they failed to consider every phase, such as prelaunch or rather preflight. The designers should have evaluated every feasible scenario, or use case, of the system, even if unlikely. Thorough use case analysis evaluates all potential "normal" and "rainy day" scenarios. Use cases could have been developed for the preflight phase, including any potential failure cases on the ground. The designers could have used these scenarios to contemplate hatch issues, coolant coil issues, and especially the egress process.

Failure Analysis

The plugs-out test of Apollo 1 was ranked as a low risk without much analysis, and NASA officials stated that they were not concerned with problems prior to launch. Although a failure analysis was conducted for the flight of Apollo 204, no failure analysis, such as a Failure Modes and Effects Analysis (FMEA), was conducted for an on-the-ground or prelaunch situation. Once identified, proper mitigation actions could have been implemented. For more information, see Part 3, Risk Management and Part 6, Safety Engineering.

Transportation System Examples

Denver Airport Baggage Handling System

- Lead Authors:
- Art Pyster and Heidi Davidz

-

This example was developed as a SE example for the SEBoK. It describes systems engineering (SE) issues related to the development of the automated baggage handling system for the Denver International Airport (DIA) from 1990 to 1995. The computer-controlled, electrical-mechanical system was part of a larger airport system.

Description

In February 1995, DIA was opened 16 months later than originally anticipated with a delay cost of $500 million (Calleam Consulting Ltd. 2008). A key schedule and cost problem—the integrated automated baggage handling system—was a unique feature of the airport. The baggage system was designed to distribute all baggage automatically between check-in and pick-up on arrival. The delivery mechanism consisted of 17 miles of track on which 4,000 individual, radio-controlled carts would circulate. The $238 million system consisted of over 100 computers networked together, 5,000 electric eyes, 400 radio receivers, and 56 bar-code scanners. The purpose of the system was to ensure the safe and timely arrival of every piece of baggage. Significant management, mechanical, and software problems plagued the automated baggage handling system. In August 2005, the automated system was abandoned and replaced with a manual one.

The automated baggage system was far more complex than previous systems. As planned, it would have been ten times larger than any other automated system, developed on an ambitious schedule, utilized novel technology, and required shorter-than-average baggage delivery times. As such, the system involved a very high level of SE risk. A fixed scope, schedule, and budget arrangement precluded extensive simulation or physical testing of the full design. System design began late, as it did not begin until well after construction of the airport was underway. The change management system allowed acceptance of change requests that required significant redesigns to portions of work already completed. The design did not include a meaningful backup system; for a system that required very high mechanical and computer reliability, this increased failure risks. The system had an insufficient number of tugs and carts to cope with the volume of baggage expected and this, along with severely limited timing requirements, caused baggage carts to jam in the tracks and for them to misalign with the conveyor belts feeding the bags. This resulted in mutilated and lost bags (Neufville 1994; Gibbs 1994).

The baggage system problems could be associated with the non-use or misuse of a number of systems engineering (SE) concepts and practices: system architecture complexity, project scheduling, risk management, change management, system analysis and design, system reliability, systems integration, system verification and validation/testing, and insufficient management oversight.

Summary

The initial planning decisions, such as the decision to implement one airport-wide integrated system, the contractual commitments to scope, schedule, and cost, as well as the lack of adequate project management (PM) procedures and processes, led to a failed system. Attention to SE principles and practices might have avoided the system's failure.

Federal Aviation Administration (FAA) Advanced Automation System (AAS)

- Lead Authors:
- Tom Hilburn, Alice Squires, and Heidi Davidz
- Contributing Author:
- Richard Turner

-

This example was created as a SE example directly for the SEBoK. It describes the Advanced Automation System (AAS), part of the Federal Aviation Administration (FAA) Advanced Automation Program. It describes some of the problems which can occur in a complex, software intensive system program if SE is not applied.

Description

In 1981, the Federal Aviation Administration (FAA) announced the Advanced Automation Program, which was established to modernize air traffic control (ATC) computer systems. A centerpiece of the project was the Advanced Automation System (AAS). AAS was the largest project in FAA's history to modernize the nation's ATC system. AAS would replace computer hardware and software as well as controller workstations at tower, terminal, and en-route facilities and allow the ATC system to accommodate forecasted large increases in traffic through the use of modern equipment and advanced software functions. (GAO 1992)

The FAA originally proposed AAS in 1982 as a project that would cost $2.5 billion and be completed in 1996. However, substantial cost increases and schedule delays beset the AAS project over its history, caused by numerous problems in AAS development:

- The project began with a design competition between Hughes and IBM. The competition involved numerous extensions and took four years to complete. Analysis by the FAA and others pointed to inadequate consideration of user expectations and improper assessment of the technology risks. (Barlas 1996)
- The FAA pushed for 99.99999% reliability, which was considered by some "more stringent than on any system that has ever been implemented" and extremely costly. (DOT 1998)
- The program created unworkable software testing schedules - "Testing milestones were skipped or shortcutted and new software was developed assuming that the previously developed software had been tested and performed." (Barlas 1996)
- There were an extraordinary number of requirements changes. For example, for the Initial Sector Suite System (ISSS), a key component of AAS, there were over 500 requirements changes in 1990. Because of these changes, 150,000 lines of software code had to be rewritten at a cost of $242 million. (Boppana et al. 2006)
- IBM's cost estimation and development process tracking used inappropriate data, were performed inconsistently, and were routinely ignored by project managers. The FAA conservatively expected to pay about $500 per line of computer code - five times the industry average. The FAA ended up paying $700 to $900 per line for the AAS software. (Gibbs 1994)
- In 1988, FAA estimated that the AAS program - both contract and supporting efforts - would cost $4.8 billion. By late 1993, the FAA estimated that it would cost $5.9 billion. Before the program was dramatically restructured in 1994, estimates had risen to as much as $7 billion, with key segments expected to be behind schedule by as much 8 years. In 1994, with significant cost and schedule overruns, as well as concerns about adequate quality, usability, and reliability, the AAS program ceased to exist as originally conceived, leaving its various elements terminated, restructured, or as parts of smaller programs. (DOT 1998)

The AAS problems could be associated with the non-use or misuse of a number of systems engineering (SE) concepts and practices: system requirements, system architecture complexity, project planning, risk management, change management, system analysis and design, system reliability, system integration, system verification and system validation/testing, and management oversight.

Summary

The AAS program was the centerpiece of an ambitious effort begun in the 1980s to replace the computer hardware and software throughout the ATC system - including controller workstations, and en-route, terminal, and tower air traffic control facilities. AAS was intended to provide new automated capabilities to accommodate increases in air traffic. After sustaining serious cost and schedule problems, the FAA dramatically restructured the program into more manageable pieces. This action included terminating major segments of the contract. (DOT 1998.)

Federal Aviation Administration (FAA) Next Generation Air Transportation System

- Lead Author:
- Brian White

-

This article describes a massive undertaking to modernize the air traffic management enterprise. The topic may be of particular interest to those involved in air transportation whether in connection with their careers or as pilots or passengers on airplanes. For addition information, refer to the closely related topics of Enabling Businesses and Enterprises and Enterprise Systems Engineering.

Background

This case study presents the systems engineering and enterprise systems engineering (ese) efforts in the Next Generation (NextGen) Air Transportation Systems by the Federal Aviation Administration (FAA 2008). NextGen is an unprecedented effort by multiple U.S. federal organizations to transform the U.S. air transportation infrastructure from a fragmented ground-based navigation system to a net-centric satellite-based navigation system. This project is unique to the FAA because of its large scale, the huge number of stakeholder(s) involved, the properties of the system of interest, and the revolutionary changes required in the U.S. Air Transportation Network (U.S. ATN) enterprise.

A sociotechnical system like the U.S. ATN is a "large-scale [system] in which humans and technical constituents are interacting, adapting, learning, and coevolving. In [such] systems technical constraints and social and behavioral complexity are of essential essence". (Darabi and Mansouri 2014). Therefore, in order to understand changes in the U.S. ATN it was seen as necessary to view it through a lens of evolutionary adaptation rather than rigid systems design. The U.S. ATN serves both military and commercial aircraft with its 19,782 airports, including 547 are commercial airports. Nineteen major airlines, with more than a billion dollars in annual total revenue, along with other 57 national and regional airlines, transport 793 million passengers and realize 53 billion revenue ton-miles.

The Air Traffic Organization (ATO) is responsible for ensuring aircraft navigation in the U.S. National Air Space (NAS) system using a five-layer architecture. Each aircraft goes through different layers and possibly various zones of this architecture as it takes off from an airport until its lands at another airport (Donohue and Zellweger 2001). However, this architecture is fragmented and many issues are raised: an airplane's path through its route is not optimized, and the path may change its direction from one zone to another, the destination airport's capacity is limited by the current regulations of minimum aircraft separation distance due to navigation limitations, the real-time weather information is not integrated into the system, and communications are mainly voice-based, etc.

In NextGen major changes to the U.S. ATN design are planned. As already stated, the navigation system will be changed from ground-based communication to satellite-based navigation. The current fragmented architecture will be integrated into a seamless net-centric information system in which the digital communication will replace the current voice communications. Moreover, weather information will be assimilated into decision making and planning across the system.

Purpose

The FAA's purpose is "to provide the safest, most efficient aerospace system in the world". Toward this end the NextGen project is aimed at enhancing the U.S.'s leadership position in air transportation.

During the last three decades the demand for air transportation shows exponential growth. In just one decade from 1995 to 2005 this demand showed a 44% percent increase. Therefore, the change in infrastructure was inevitable. Moreover, 9/11 attacks on the U.S. ATN emphasized this need for change. The combination of a requirement for a safer and more secure network and increasing demand was the motivation for President Bush to enact the Vision 100-Century of Aviation Reauthorization Act on 2003. A major part of this Act was to revolutionize the U.S. ATN by means of the NextGen project. The first integration plan of the project was released in 2004, and the project is estimated to continue until 2025.

The demand behavior of the U.S. ATN shows diverse degrees of congestion among airports. Although there are multitudes of airports in the system, the top 35 most congested airports carried more than 60% of the total traffic consistently during the period of 2000 to 2008. Because the growth of the network demand is not proportional, the demand in congested airports will be even higher.

A study by the Joint Planning and Development Office (JPDO) shows that flight delays in the current network will cause $6.5 billion of economic loss until 2015, and $19.6 billion until 2025. By implementing NextGen the delays are estimated to be reduced by 38% until 2020. Moreover, aircraft CO2 emissions are a major part of environmental pollution in crowded cities; these will be reduced by 14 million metric tons by 2020. The current level of jet fuel usage is also a known problem because of increasing fuel prices. The NextGen project will improve fuel usage by 1.4 billion gallons cumulative through 2020.

NextGen is pursuing multiple goals to retain the U.S. leadership in aviation, to expand the U.S. ATN capacity, to continue to ensure safety, to increase environment protection, to help ensure national air defense, all generally helping to increase the nation's security (JPDO 2007a).

Eight general capabilities are defined in conducting this mission: (1) network-enabled information access, (2) performance-based operations and services, (3) weather assimilated into decision making, (4) layered adaptive security, (5) positioning, navigation, and timing (PNT) services, (6) aircraft trajectory-based operations (TBO), (7) equivalent visual operations (EVO), and (8) super-density arrival/departure operations.

To create the desired capabilities, general areas of transformations are defined as air traffic management operations, airport operations and infrastructure services, net-centric infrastructure services, shared situational awareness services, layered and adaptive security services, environmental management services, safety management services, and performance management services. The detailed changes in each area are discussed in Concept of Operations for NextGen (JPDO 2007a).

Challenges

An instructive part of this case study is observing evolution in understanding challenges from initial steps of the project through current efforts for delivering it. As an overall conclusion, the perspective on challenges shifted from technical problems and intra-organizational issues to more enterprise-wide issues.

The NextGen Implementation Plan 2008 discussed the following challenges (FAA 2008):

- performance analysis, to understand and assess operational capabilities
- policy, to balance responsibility between humans and automation, for environmental management processes, and for global harmonization strategies
- acquisition workforce staffing
- environmental planning, to resolve conflicts with local environmental constraints
- security

- transition from current ground-based navigation to automatic dependent surveillance – broadcast (ADS-B) technology.

A more recent report on Targeted NextGen Capabilities for 2025 (JPDO 2011) highlights the effect of the multi-stakeholder nature of the project on raising additional challenges. Achieving Interagency Collaboration is the first issue, which is important in implementing security, safety, policy making, and technological advancement.

Increasing capacity, reducing delay and protecting the environment are the main three promises of the NextGen project. However, reaching the defined high standards is not an easy task. A major part of this challenge is integrating new technologies into legacy systems, aircraft, airports, facilities, and organizations. Airlines and general aviation pilots resist the expense of additional avionics and communications equipment, even though it bolsters the common good of air travel.

Maintaining airports and airspace security requires coherent and harmonious work of multiple U.S. agencies. The core of this challenge is not just changing the technology but also the processes, organizational structures, and enterprises to meet the new requirements of security.

Moreover, the need for greater information sharing in this net-centric environment is a challenge. The current culture of limited information sharing in which inter-organizational and intra-organizational information is strictly divided creates tension in a seamless information sharing infrastructure. In addition to that, the responsibility of generating, sharing, and utilizing useful information should be addressed in advance to avoid costly mistakes.

Verification and validation of NextGen deliverables is a major issue. The traditional systems engineering methods of verification and validation are tailored for testing an isolated system, while by definition a project like NextGen requires new methodologies of verification and validation beyond the scope of one system. The knowledge and experience of advancement in systems engineering in this area can be of priceless value for future projects.

Balance between human decision-making and automation is required to ensure a correct policy for increasing traffic and safety concerns. Changes in both human resource and technological facilities are required to effectively address this challenge.

The support of local communities is essential to facilitate development of the U.S. ATN and its physical infrastructure.

Communication, navigation, and surveillance systems in NextGen are going through major changes in terms of capacity and technology. However, planning required backups for them in case of any emergency is an area of challenge in developing NextGen.

The rise of Unmanned Aircraft Systems (UASs) provides significant opportunities for both military and commercial applications. However, integrating them into the NAS and developing policing and strategies for safe and secure use is a concern for the revolutionized U.S. ATN.

And finally realizing the benefits of NextGen is dependent on the critical mass of early adopters, similar to any technological advancement. Therefore, the NextGen project authority requires well-defined policies for motivating stakeholders' participation.

Systems Engineering Practices

The FAA NextGen is not just a revolution of the U.S. air transportation infrastructure, but also a shift in its enterprise. The enterprise architecture document, which is developed by JPDO, provides an overview of the desired capabilities (JPDO 2007b).

The enterprise architecture is described using Department of Defense Architecture Framework (DoDAF) and the Federal Enterprise Architecture (FEA). DoDAF is used to describe the operational aspects of the project. The three views of DoDAF, the Operational View (OV), the Systems View (SV), and the Technical Standards View (TV), are presented in the enterprise architecture document. The Overview and Summary Information (AV-1) is the formal statement about how to use the architecture, the Integrated Dictionary (AV-2) defines the terms in the document, the

Community Model (OV-1) presents a high level depiction of the NextGen community, the Operational Node Connectivity Description (OV-2) presents the information flow among operational nodes in the system, Operational Information Exchange Matrix (OV-3) details the description of information flow in OV-2. Other architectural views of the system based on DoDAF are the Activity Model (OV-5) which documents activities (functions and processes), the Operational Event/Trace Description (OV-6c) is a part of sequence and timing description of activities, the System Functionality Description (SV-4) explains system functional hierarchies, and the Operational Activity to System Functionality Traceability Matrix (SV-5) is specification of relationships between operational activities in architecture and functional activities. However, a challenging part of applying this Enterprise Architecture is transformation from legacy systems to the new NextGen. This transformation is the ultimate test for relevance and comprehensiveness of the developed Enterprise Architecture.

Acquisition is the heart of systems engineering activities in the FAA NextGen project. As mentioned in Challenges above, the current practice of verification of validation in systems engineering (SE) is geared toward single isolated systems, rather than a myriad of interconnected system of systems (sos). Moreover, the capabilities of NextGen are interdependent, and different programs rely on each other to deliver the promises. 250 unique and highly interconnected acquisition programs are identified in the FAA's Capital Investment Plan, and these are to be delivered by 1820 FAA acquisition professionals. In addition, program complexity, budget uncertainty, and the challenge of finding acquisition professionals present other problems. The experience of systems acquisition in NextGen can provide a useful knowledge for future similar projects.

Lessons Learned

Although major portions of the FAA NextGen project are technical transformations and physical infrastructure developments, the transformation in the aviation enterprise is important but to some degree neglected. Part of the issue might be the fact that this transformation is beyond the responsibility and capability of FAA. However, to accomplish NextGen's perceived benefits it is important to realize the effects of legacy systems, and most importantly the legacy enterprise architecture of the U.S. ATN. Many of the actual challenges in the system arose because of this inattention.

The sequestration in the U.S. government, the Budget Control Act of 2011, has cut the project funding substantially in recent years. As a result the project schedule and portfolio are subject to constant and wide-spread changes. The FAA was focused on delivering Optimization of Airspace and Procedures in the Metroplex (OPAM) program which is designed to reduce the delay, fuel consumption, and exhaust emission in busiest airports. The three areas of Houston, North Texas, and Washington D.C. were planned to complete the design phase on 2013 and start implementation.

Out of 700 planned ADS-B ground stations, 445 were operational on February 2013. ADS-B capability is a NextGen descendant of current radar systems and provides situational awareness for the players in the NAS using the Global Positioning System (GPS) and Wide Area Augmentation System (WAAS).

On the enterprise part of the project, the FAA Modernization and Reform Act of 2012 provided financial incentives for airlines and commercial aviation manufacturers to implement the required equipment in their aircraft. These incentives are designed to engage the air transportation community in the project and to create the critical mass of equipped airplanes.

There are considerable practices in applying NextGen. Establishment of the JPDO made the efforts of the project more coherent and integrated. JPDO's main responsibility is to coordinate development of NextGen. The role of this organization is to represent multiple stakeholders of the project, which enables it to resolve possible conflicts of interests inside one entity. Moreover, such an organization provides a venue for technical knowledge-sharing, creating a consensus, and making an integrated system.

Emphasizing delivery of the mid-term objectives of NextGen is another lesson of the project. It was a well-known practice documented by Forman and Maier to establish mid-points for complex projects (Forman 2000). Developing

a mid-level system provides the system designers an opportunity to examine their underlying assumptions, to identify best practices and heuristics in the context of the project, and to reapply the acquired knowledge thorough evolutionary developments. A major shift in the policy of FAA in recent years was to focus on delivering project mid-term objectives.

There are unique characteristics of NextGen which makes it a valuable case for learning and replicating to other complex transformation projects of sociotechnical systems. The scale of the project for infrastructure transformation is unprecedented. The system includes legacy systems and cutting edge technology, and its performance is based on their coherent work. The project implementation is dependent on involved participation of multiple governmental and commercial organizations. Moreover, this case-study provides a great investigation in enterprise governance and enterprise transformation beyond a single organization.

Reverse Engineering a UAV Prototype using Agile Practices

- Lead Author:
- Phyllis Marbach

-

This example shows how Agile Practices were applied to an unmanned air vehicle (UAV) that had been developed as a prototype and was intended to be produced and marketed (Marbach 2012). At the time it was required to have the Federal Aviation Agency (FAA) approve the use of a UAV in populated areas. FAA required artifacts such as requirements, architecture representations and test procedures to grant this approval. A team was established to reverse engineer the artifacts needed from the operational prototypes being flown at the time. The test manager requested that the life cycle process to produce these artifacts be agile. Stakeholder needs were determined, and a plan was written to describe the problem and the process to be applied. Then the approach was presented to the team, the product backlog was developed, and a training and planning session was started.

Description

The agile process is described in the SEBoK here. When defining requirements (Carlson 2010) proposes that the requirements be identified, gathered, defined, and developed in iterations (or sprints). These requirements are written in the User Story format and controlled and managed in a product backlog. The User Stories in the Product backlog are selected and estimated by the team based on importance and need. The most important user stories (or requirements) are prioritized and moved to the top of the product backlog. Then those User Stories are broken into tasks and the tasks are estimated. The number of tasks that the team can complete are then put into the Sprint Backlog (or iteration backlog) and those tasks are then worked on by the team. For this work the UAV and its code were already operational. We had working code, a test bed, user interfaces and user procedures. The goal was to produce requirements documentation, architecture and design diagrams, a trace matrix of tests to requirements, software test descriptions and a Hazard Analysis to take before the FAA.

The team assembled were experienced engineers, but not with this UAV system. There were UAV subject matter experts (SMEs) still on the program, but they were not always available to answer questions or come to reviews. There was existing documentation in program repositories such as charts and operator procedures, but we did not know where to find this information. Given these challenges it was decided to use collaborative tools to manage the information as it was discovered and make it visible to the team and the UAV SMEs.

The first set of information produced was the product backlog. An example of the product backlog is shown in Figure 1. Epics are a set of User Stories that take more than one iteration to complete. A user story is broken into tasks such as those shown in Figure 2. These templates were developed to understand the scope of each task and what the definition of done for that task was. The goal was to identify tasks that take a maximum of 16 work hours to complete. The product backlog was developed and managed in an Application Lifecycle Management (ALM) Tool. Our team did a trades study when selecting a tool for use. Parameters considered in the trade included ease of use, cost, and features of the tool itself. The tool selected was VersionOne.

The team then determined what collaboration tool would be used to make our discovered information visible. The requirements for this tool were: easy to access, easy to use, easy to comment on and easy to change. At the time these tools were available: Mediawiki, an open source, TWikiTM, another open source, Confluence, SharePoint, and Socialtext. It was decided to use TWikiTM.

For each of the epics in work, such as “Power On”, the Description of Functionality was written in the collaboration tool. Figure 3 shows the list of content in the collaboration tool for the artifacts being developed.

- **30 Epics were created from the User Interface Features, examples:**
  - Power On
  - Start Up Feature
  - Shutdown Feature
  - Operate Component
  - Operate Another Component
- **Product Owner prioritized the most important ones**
- **Each epic has 5 significant backlog items (took 3 Iterations to reach these 5):**
  - Functional Analysis
  - Requirements
  - Hazard Analysis
  - Draft Test Procedure
  - Finalize Test Procedure

Figure 1. Example Product Backlog for an Unmanned Air Vehicle (UAV) (Marbach 2023, used with permission)

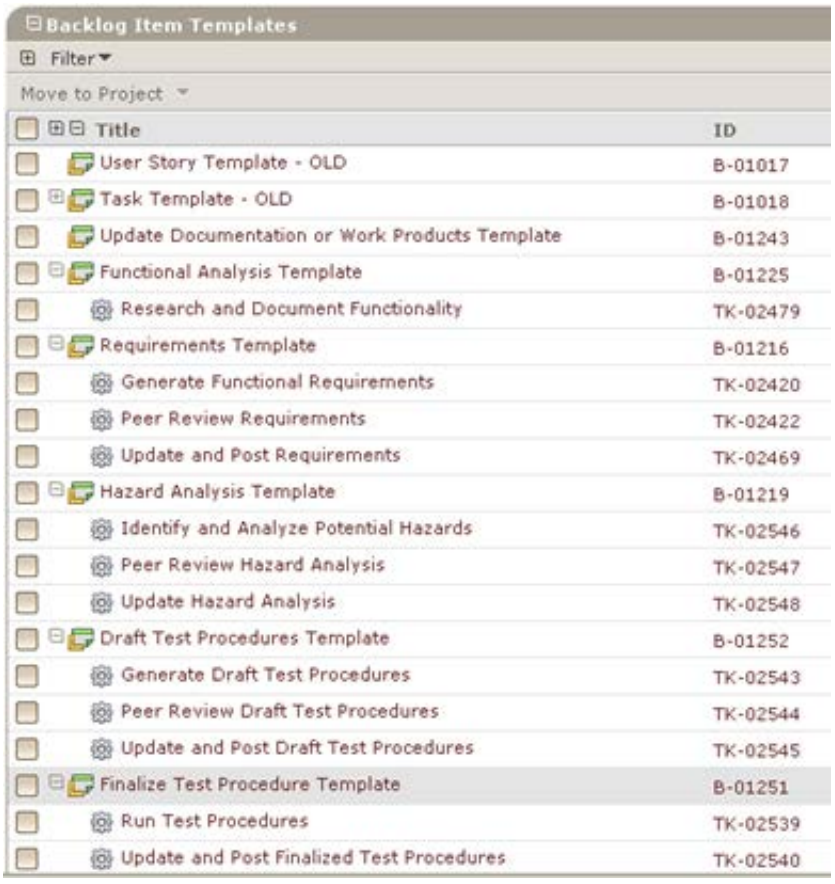

Figure 2. User Story Templates and Task Templates for Consistent Development (Marbach 2023, used with permission)

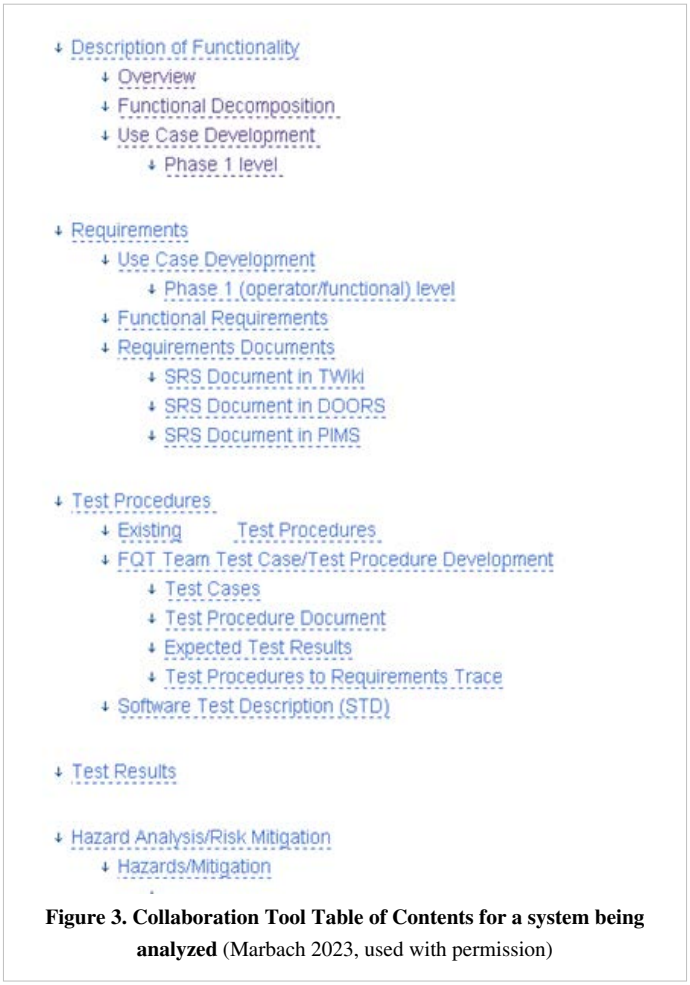

Figure 3. Collaboration Tool Table of Contents for a system being analyzed (Marbach 2023, used with permission)

The Collaboration Home Page had an introduction about the analysis underway. It had links to a list of functional threads that were links to the work products themselves. There were also links to the references used, links to the test environment information and links to templates for the work products with instructions. The work products being developed, as shown in Figure 3, were Collaboration Tool Templates, Functional Descriptions, Requirements including Use Cases, Hazard Analysis and Risk Mitigation, and Test Procedures including Test Cases and Test Descriptions.

Once the requirements were complete for one Epic, such as “Power On” the material in the Collaboration Tool was exported into a Word Document and that was parsed into a Requirements Management tool. This team used the Dynamic Object-Oriented Requirements System (DOORS). The final Software Requirement Specification (SRS) was created from DOORS. After peer review the release documents were baselined into the Data Management Tool Repository that provided Configuration Management control. The Integrated Toolset used for this project is shown in Figure 4.

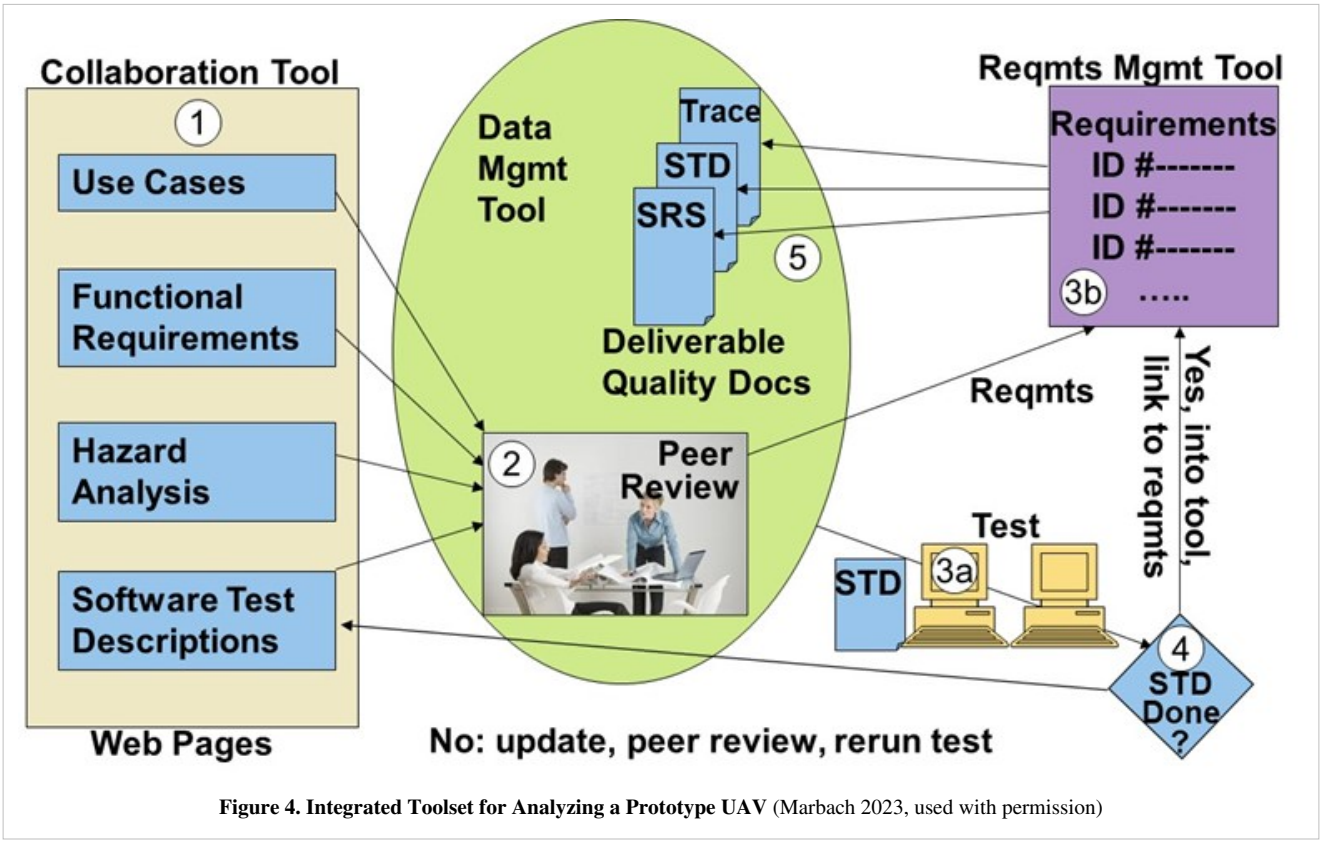

Figure 4. Integrated Toolset for Analyzing a Prototype UAV (Marbach 2023, used with permission)

The sequence of development started with the prioritized user story to be worked first. Then the Collaboration tool was used to capture the information that members of the reverse engineering team worked with SMEs to reach an understanding of the functional requirements, hazard analysis and software test descriptions for the user story in development. A formal peer review was conducted and when agreed it was ready those documents were parsed into the requirements management tool. The Software Test Description (STD) was used to test the UAV code using the test platform. If the STD is determined to be complete, then it is also parsed into the requirements management tool and traced to the requirements that have been verified by testing. From the requirements management tool formal artifacts such as the Software Requirement Specification, the Software Test Description and the Trace Matrix were produced. Those were put into a configuration management tool. If the STD used for the testing was not Done then any markups were made into the Collaboration Tool and the Peer Review was conducted again. Essentially, each iteration resulted in potentially deliverable products that could be delivered to a stakeholder.

The data management tool, shown in Figure 4 by the green oval contained a repository of draft folders, peer review records, action items created, tracking and closure, a repository of release folders, the calendar, meeting notifications, distribution lists, access control to records, configuration management workflow and approvals, and it provided collaboration across companies, subcontractors, and customers.

The documentation created included software requirements specification that was created epic by epic rather than all at once, software test descriptions created as each feature is analyzed, and a Hazard Analysis being performed one epic at a time. These documents were updated each increment. An increment is a set of iterations. Each backlog item included conducting peer reviews of the content, as shown in Figure 2 list of tasks of each user story. Records of the peer reviews were maintained in the data management tool as mentioned above. The definition of done for these artifacts was that the work was not complete until the information was posted into the Requirements Management Tool. The Software Test Descriptions were linked to the requirements in the Requirements Management Tool thus beginning the Trace Matrix.

The Agile Practices described in this article can be mapped to LEAN Disciplines as shown in Table 1.

Table 1. Agile Practices Drive LEAN Disciplines (Used with Permission)

LEAN Disciplines	Agile Requirements Analysis
1. Establish Clear Priorities	1. Product backlog is always prioritized; Team works on highest priority items first
2. Eliminate Bad Multitasking – Focus and Finish	2. Team is shielded from interruptions that cause bad multitasking
3. Limit the Release of Work in Process (WIP) to Deliver Earlier	3. Tasks are pulled from the iteration backlog one at a time to limit individual WIP
4. Prepare! Start to Finish	4. Requirements are not selected from the product backlog until everything needed is available
5. Use Checklists to Prevent Defects and Traveled Risk	5. Checklists and guides are used to prevent costly rework
6. Face into and Resolve Issues Quickly	6. Daily stand-up meetings force issues and risks to be identified and resolved quickly
7. Drive Daily Execution	7. Daily stand-up meetings drive team-based execution

Summary

Systems engineering best practice is to perform requirements analysis, verification and validation as a system is being developed. Artifacts are created and configuration controlled as the system matures. This example describes how an existing operating prototype could be transitioned to a production system by performing requirements analysis, risk mitigation and hazard analysis even after the prototype is developed and operational. There is value in performing these system engineering tasks for an existing prototype to verify it is safe to operate and to achieve approval to fly. Using iterative and incremental development of these artifacts limited the work in process (WIP). The whole team worked one epic at a time to produce artifacts that addressed that one epic and verified the requirements, testing and analysis of hazards relative to that one epic, such as “Power On”. Then they would work the next epic focusing on one capability at a time therefore reinforcing each other’s work quite effectively.

Lessons Learned

- Developing Systems Engineering products such as Systems Requirements Specifications, Hazards Analysis, Test *Procedures, and Verification Trace Matrix in an iterative incremental way is effective.
- Some new to using these principles and methods did resist at first but then saw the value and became advocates of the iterative incremental process.
- The use of tools helped keep the work visible, aiding in communication and accuracy.
- Access to Subject Matter Experts (SMEs) was critical to producing accurate products.
- The team focused on known elements first. Then the knowledge learned was applied to elements with more uncertainty. This applies the Lean Principle of limiting the work in process.
- The team did not start work on an element until they had what was needed to accomplish the analysis. This applies the Lean Principle of working start to finish.

UK West Coast Route Modernisation Project

- Lead Authors:
- Tom Hilburn, Heidi Davidz, and Alex Lee
- Contributing Authors:
- Alice Squires and Richard Turner

-

This example was created as a SE example directly for the SEBoK. It describes the United Kingdom West Coast Main Line railway project and some of the problems which occurred on this project before the implementation of SE. It also discussed the value of applying some aspects of SE, even if this is done later in the project.

This example is based on information from a report by the UK National Audit Office (NAO 2006). It also uses an INCOSE publication on systems engineering case studies (INCOSE 2011) to help structure its conclusions.

Description

The West Coast Main Line (WCML) is a principal United Kingdom (UK) railway artery serving London, the Midlands, the North West and Scotland. The Line is responsible for over 2,000 train movements each day, with more than 75 million rail journeys made each year on the route. It accounts for 43% of Britain’s UK freight market (Railway People 2011). In 1998, the British government embarked on a modernization program called the West Coast Route Modernisation (WCRM) project, to carry out a significant volume of modernization work between 1998 and 2008, delivering increased capacity and reduced journey times as well as replacing worn-out parts of the railway. It was a challenging job involving 640 kilometers of track—much of which was incapable of carrying high-speed rail cars. Some sections were seriously dilapidated, and new trains would require a complete overhaul of signaling, power supply, and switching systems.

Early on, the WCRM upgrade had serious problems. A major complicating factor was the introduction of a new signaling technology that was designed to allow improved services for new trains running at 140 miles per hour. By 2001, neither the rail infrastructure upgrade nor the new trains were on course for delivery as expected in the 1998 agreement. By May 2002, the projection of the program’s final cost had risen from £2.5 billion (in 1998) to £14.5 billion but had delivered only a sixth of the original scope.

In January 2002, the UK Secretary of State instructed the Strategic Rail Authority (SRA) to intervene and find a way to renew and upgrade the WCML. An SRA analysis identified the following issues:

- The program lacked direction and leadership before 2002.
- The project did not have a delivery strategy and there was no central point for responsibility and communication.
- There was a lack of openness and communication regarding the program with interested parties before 2002 and there was a lack of stakeholder management.
- Scope changes arose because WCRM did not have an agreed-upon specification that matched required outputs with inputs.
- There was inadequate knowledge about the West Coast asset condition.
- Technology issues related to the decision to replace conventional signaling with unproven moving block signaling introduced major risk into deliverability and cost before 2002. These technology issues caused scope changes and program delay.
- Project management (PM) was weak, with a lack of senior management skills, too many changes in personnel, and ill-defined and fragmented roles and responsibilities. There was no integrated delivery plan and there was limited oversight of contractors. Poor management of contracts added to costs.

In order to remedy the situation, the SRA initiated the following actions, which align with generally accepted systems engineering (SE) practice:

- A clear direction for the project was developed and documented in the June 2003 West Coast Main Line Strategy, specifying desired goals and outcomes.
- A clear, measurable set of program outputs was established, along with more detailed infrastructure requirements, which were then subject to systematic change control and monitoring procedures fixing scope. Contractors were invited to tender complete detailed designs and deliver the work to a fixed price.
- Clear program governance structures were instituted.
- The SRA consulted widely with stakeholders and, in turn, kept stakeholders informed.

A National Audit Office (NAO) report concluded that the new arrangements worked well and that there were benefits to this approach (NAO 2006). Until this time, one of the program's key constraints and cost drivers had been the ability to access certain areas of the track. The new approach facilitated the ability to obtain possession of the track for engineering work, which was crucial to delivery. The new approach also enabled the program to identify opportunities to reduce the total cost by over £4 billion.

The NAO report also discussed a business case analysis by the SRA that identified the following benefits (NAO 2006):

- benefit:cost ratio for the enhancements element was 2.5:1;
- journey times and train frequencies exceeded the targets set out in the 2003 West Coast Strategy;
- growth in passenger numbers exceeded expectations (e.g., by 2005-06, following Phase 1 of the West Coast program, annual passenger journeys on Virgin West Coast grew by more than 20%); and
- punctuality improved (e.g., by September 2006, average time delays on Virgin West Coast trains have been approximately 9.5 minutes, a 43% improvement on the average delay of 17 minutes in September 2004).

The WCRM problems could be associated with a number of systems engineering concepts and practices: stakeholder needs definition, planning, analysis of risks and challenges of new technology and associated risk management, decision management, configuration or change management, information management, and management oversight.

Summary

The WCRM project illustrates that when SE concepts and practices are not used or applied properly, system development can experience debilitating problems. This project also demonstrates how such problems can be abated and reversed when SE principles and methods are applied.

Standard Korean Light Transit System

- Lead Authors:
- Heidi Davidz, Alice Squires, and Chuck Calvano
- Contributing Author:
- Richard Turner

-

This example was created as a SE example directly for the SEBoK. It deals with systems engineering (SE) concepts and guidelines applied to the development of the Standard Korean Light Transit System (SKLTS). In Korea, local authorities had historically been interested in light transit to help resolve their transportation problems. The SKLTS was a joint effort between local authorities and the central government. It was built to provide a standard platform on which any local authority could construct its own light transit system. The issues of stakeholder needs definition, safety, and reliability, availability, and maintainability were critical to the success of this system.

Description

The elements of the SKLTS were classified into four groups (as shown in Figure 1): trains, signal systems, electric and machinery (E&M) systems, and structures. Trains and vehicles were to be automatically operated, without need for human operators. Operation systems and their interfaces were based on digital signals and communications. For SKLTS, SE-based design activities focused on reliability, availability, maintainability, and safety (RAMS), and were integrated into project management (PM) activities during all phases.

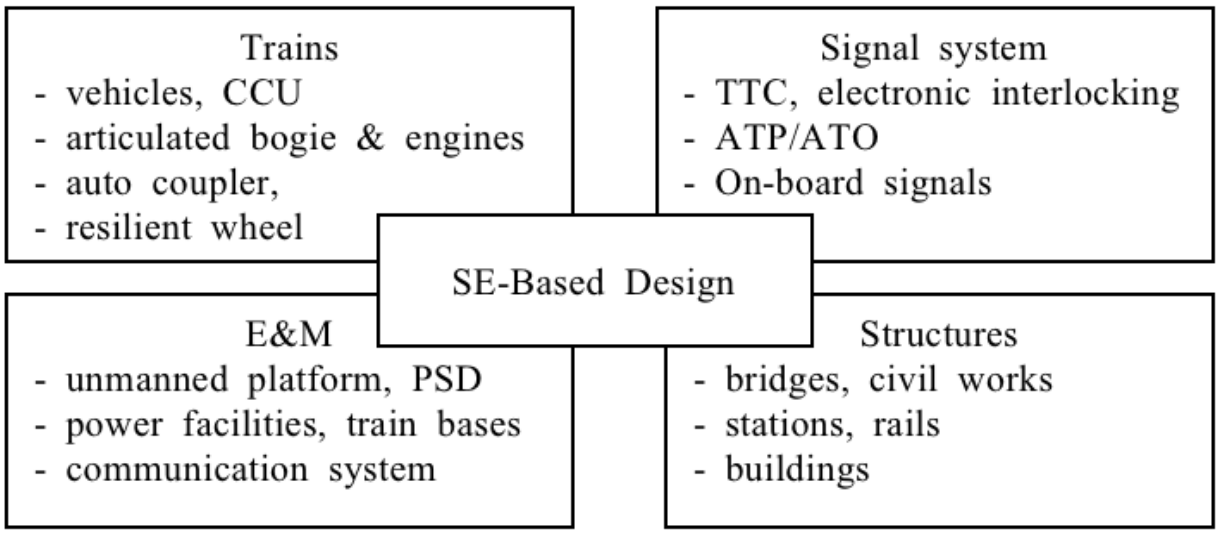

Figure 1. Subsystems of the SKLTS (Ahn, 2005). (Notes: CCU: Central Control Unit; TTC: Total Traffic Control; ATP: Automatic Train Protection; ATO: Automatic Train Operation; PSD: Platform Screen Door) Reprinted with permission of *Journal of the Korean Society for Railway*. All other rights are reserved by the copyright owner.

The project life cycle for the SKLTS is summarized in Figure 2. It consisted of 7 phases: concept studies, concept development, preliminary design, design, system production and testing, performance evaluation, and operation/maintenance/close-out (OMC) - please see (Choi 2007) and (Chung et al. 2010) for further details. These phases, with the exception of the production and test phases, are completed through an evaluation and decision point (EDP) (milestone), depicted as a colored circle in Figure 2. These EDPs correspond to common life cycle artifacts such as requests for proposal (RFPs), proposals, preliminary design reviews (PDRs), and critical design reviews (CDRs).

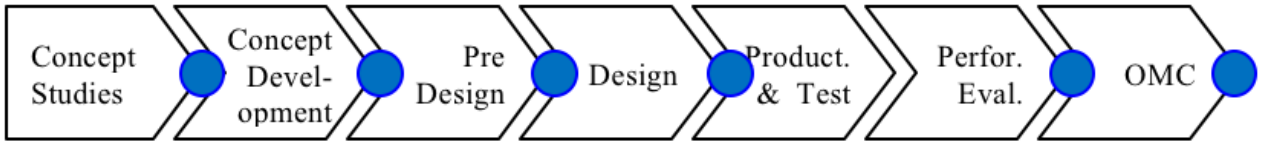

Figure 2. 7 phases of the SKLTS development (Ahn 2005). Reprinted with permission of the *Journal of the Korean Society for Railway*. All other rights are reserved by the copyright owner.

During the SKLTS development, SE activities were focused on RAMS as summarized in Table 1.

Table 1. The SE Framework of the SKLTS (Ahn 2005). Reprinted with permission of the *Journal of the Korean Society for Railway*. All other rights are reserved by the copyright owner.

Phases	Safety	Reliability	Function	Performance
Concept studies	• Requirements analysis	• Identifying RAM conditions • RAM allocation	• System configuration • Interface management	• Performance simulation
Concept development & pre-design	• Safety planning • Defining safety procedures & levels	• RAM planning • Initial availability analysis	• Defining scenarios and alarm procedure • Pre-designing command rooms	• Interface analysis

Design	• Hazard log • Safety case analysis • Risk analysis	• Reporting RAM analysis • RAM analysis of auxiliary systems	• Defining alarm systems • Train analysis • Functionality analysis of stations	• Interface analysis
Performance evaluation	• Safety test planning & testing	• Verification and Validation (V&V) RAM • Maintainability test	• System test planning and testing	• Performance test planning & testing
Initial Operation	• System acceptance • Driver certification	• RAM monitoring • FRACAS*	• Analyzing systems • Identifying improvement points	• Performance monitoring

*FRACAS: Failure Reporting & Corrective Action System

In the "concept studies" and "concept development" phases, requirements included the RAMS objectives. Planning activities in this phase included the scheduling of various tests and evaluations to be conducted after system design. The basic layout of rails and command rooms was also proposed. Finally, it was during this phase that interface management procedures and relationships between requirements and systems were defined. For RAMS engineering, it was also important to establish associated plans and criteria (e.g., RAM plans, safety plans, service availability, etc.).

During the pre-design phase, the basic architecture of the system was determined for safety planning, RAMS planning, and operational scenarios. Interfaces among subsystems, management procedures for contractors and legal regulations were defined. were defined as well as management procedures for contractors and legal regulations. The functional analysis dealt with timeline, accuracy of stop points, and trip times. Pre-design activities also included the specifications of major system elements such as signal systems, trains, and interfaces. For RAMS engineering, safety scenarios were defined, and the hazard and risk analyses were performed.

During the design and performance evaluation phases, hazard log and RAMS analyses were performed to ensure that each subsystem met safety requirements. The specifications of alarm systems and stations were also defined. In addition, V&V and test procedures were determined for performance evaluation. During the design phase, a design/construction interface manual (D/CIM) was developed and applied to ensure integrated and consistent design. (Bombardier, 2005.)

Because SKLTS was designed as an automatically-driven system, RAMS issues were critical to its success. The safety and reliability of the SKLTS were evaluated on a test railway that was constructed to standard specifications. Data was gathered from existing Korean light rail systems, as well as the light rail systems from other countries, to support V&V activities.

Various methods were applied for achieving the RAMS objectives, including RAMS requirements analysis, safety and RAMS planning, utilization of systems scenarios, and construction risk analysis.

Initial operation of SKLTS was allowed only after the system was formally accepted and operators were properly certified. During test operation, RAMS performance was continuously monitored and system scenarios were used successfully to evaluate the dynamic behavior of the system. A failure reporting and corrective action system (FRACAS) was used to gather accident and failure data. Continuous improvement when the system is in normal operation was identified as a requirement; the results from the FRACAS will be used to support improvement of the system, maintenance, and improvement of procedures.

Summary

Korean local authorities have successfully introduced the SKLTS to their precincts with some modifications. Successful examples include the Inchun Airport Line and the Seoul 9th Subway Line. One lesson learned that was identified was that requirement analysis, especially in the first few phases, should have been more complete.

Utilities Examples

Northwest Hydro System

-

This case study presents the Northwest Hydro System (NwHS), which is situated in the northwestern United States (the Northwest). NwHS comprises a large number of loosely coupled autonomous elements (hydroelectric dams) that operate in a complex environment of social, regulatory, and ecological contexts. It is instructive to note that the NwHS is characterized as a project that is concerned with planning, developing, and maintaining a hydroelectric system that has evolved, and continues to evolve, over time. Each of the hydroelectric dams within the NwHS is also referred to as a project, which indicates that the individual elements of the NwHS are also evolving over time (FWEE 2016).

Background

As is shown in this case study, NwHS is an adaptive and reconfigurable system that exists within a framework of policies, rules, regulations, and agreements. The NwHS is analyzed using each of the four provisioning paradigms in SEBoK Part 4: product system engineering; service system engineering; enterprise system engineering; and system of systems engineering.

NwHS encompasses the Columbia River and its tributaries. The headwaters of the Columbia are in the Rocky Mountains of British Columbia, Canada. The river flows south into the United States and then east to west; it forms the north-south border between the states of Washington and Oregon in the U.S. and empties into the Pacific Ocean near Astoria, Oregon. The Columbia River drainage basin (Columbia and tributaries) is roughly the size of France and extends across seven U.S. states and British Columbia (Col 2016).

The Columbia River has 14 hydroelectric dams (hydro dams) on its main stem. In total, there are more than 250 hydro dams in the Columbia River Basin, each of which has a generating capacity of five or more megawatts of electricity. The NwHS produces approximately one-third of all hydroelectric power generated in the United States - more than any other North American hydroelectric system. The amount of electrical power generated by the NwHS fluctuates between 50% and 75% of all electricity used in the Northwest; other sources include coal, natural gas, nuclear, wind, and solar. Excess electrical energy generated by NwHS is sold to other electrical grids. There are more small hydro dams than large dams. Small hydro dams have a generating capacity of 100 kilowatts to 30 megawatts; large hydro dams have a capacity of more than 30 megawatts. In addition, there are numerous micro dams that can each generate fewer than 100 kilowatts. Most micro dams provide power to isolated homes or small communities but some are elements of the NwHS and sell power to utilities (DOE 2016). Utility companies own some of the dams, some are locally and privately owned, and some are owned and operated by federal agencies.

The Bonneville Power Administration (BPA) provides about one-third of the electrical power generated by NwHS and used in the Northwest; BPA is a federal nonprofit agency – it is part of the U.S. Department of Energy. It is self-funded and covers its costs by selling electrical power generated by 31 federal hydro dams in the Columbia River Basin. The U.S. Army Corps of Engineers and the Bureau of Reclamation operate the dams.

The Bureau of Reclamation also operates a network of automated hydrologic and meteorologic monitoring stations located throughout the Northwest. This network and its associated communications and computer systems are collectively called Hydromet. Remote data collection platforms transmit water and environmental data via radio and satellite to provide near-real-time water management capabilities. Other information, as available, is integrated with Hydromet data to provide timely water supply status for river and reservoir operations (USBR 2016).

Distinguishing characteristics of individual hydro dams are their capacity to generate electrical energy and their physical structure. Several factors contribute to the differences in generating capacity of hydro dams: the number of turbines/generators; the flow rate of a river or tributary; the amount of elevation that water falls in order to spin the turbines; and environmental factors such as providing for fish passage and regulating water flow to provide irrigation water and maintain downstream ecosystems.

Dam structures include storage dams, run-of-river dams, and pumped storage dams (DOE 2016). A storage dam retains water in a reservoir for future use. A run-of-river dam harvests the energy in a river as it flows through the dam but does not impede the flow. Pumped storage dams use generated electricity to pump water back up to a storage reservoir during times of low demand for use during times of high demand. Pumped storage dams are not common in the NwHS.

Purpose

NwHS has three primary goals (NwHS 2016):

1. To provide most of the Northwest's "firm-energy" needs.
2. To maximize "non-firm" energy production.
3. To maintain the ecological environment.

Firm energy is the amount of electricity the Northwest will need each year. Planners rely on NwHS and other sources to produce enough firm energy to ensure that sufficient electricity will be generated to meet estimated needs (energy sources include hydroelectric, nuclear, coal, natural gas, solar, and wind). NwHS "firm energy" is the amount of electricity that can be generated by NwHS when the amount of available water is at a historical low, thus guaranteeing the amount of energy the NwHS can provide.

Non-firm energy is the electricity generated when the annual hydrologic cycle makes more water available for power generation than in a historically low-water year. Non-firm electricity generated by hydro dams is generally sold at a lower price than the alternatives of electricity generated by nuclear, coal, or natural gas thus making it more attractive to customers. Excess non-firm electricity is also sold to interconnected regional grids when the demand on those grids exceeds supply.

Other goals for NwHS include flood control, navigation, irrigation, and maintaining the water levels of all reservoirs.

Challenges

The NwHS is a large, complex system that has many challenges to be met.

NwHS hydro dams have varying design details (e.g., the types of turbines, generators, control systems, and fish passage facilities used). This makes routine maintenance, retrofitting, and other sustainment issues unique for each dam.

Safety and security (both physical and cyber) are common challenges for all dams; cyber security is a growing concern. Smaller dams, having fewer resources, may be more susceptible to cyber attacks than larger ones. It has been reported that on 12 occasions in the last decade hackers gained top-level access to key power networks (HLS 2010) (Cyber 2015).

Run-of-river hydro dams do not store water. They may not be able to meet their firm energy commitments when rivers are lower than anticipated and flowing slowly.

The ways in which electricity generated by a dam is transmitted and sold to utilities and large industrial customers varies widely. For instance, the Bonneville Power Administration transmits and sells power generated by federal dams. Non-federal operators must manage transmission and sale of power produced by their dams.

Depending on factors such as size, structure, location, and ownership of each dam, a large number of policies, regulations, and agreements have dramatically different effects on how dams are operated.

Some of the most contentious environmental issues are associated with maintaining the ecology of the rivers, preserving salmon and other fish, and providing sufficient irrigation water while preserving sufficient reservoir water to meet firm-energy demands (Speakout 2016).

Preserving the salmon population endangered by dams is a continuing challenge. Salmon populations have been depleted because dams impede the return of salmon to upstream spawning beds. Native Americans advocate for their traditional fishing rights, which conflict with governmental policies intended to maintain healthy salmon populations in the Columbia River Basin (Impact 2016). The National Marine Fisheries Service has recently declared that salmon recovery is a higher priority than all other purposes except flood control at 14 federal dams.

Systems Engineering Practices

The Northwest Hydro System is a large, complex system composed of loosely coupled autonomous elements; each dam operates semi-independently within a large network of similar entities and contextual constraints. The NwHS evolves over time: some dams have been retrofitted to increase power generation capability or to reconfigure connections to electrical transmission lines; new dams have been constructed; and some existing dams have been decommissioned and removed.

Human elements of NwHS include: operators; maintainers; regulators; and inspectors. Others are suppliers to NwHS (vendors and contractors); some humans are users of the electricity generated by NwHS (businesses and home owners); and some are stakeholders who depend on and are impacted by the NwHS (utilities, large industries, farmers, ranchers, homeowners, ecology advocates, Native Americans, towns).

The context of NwHS includes natural elements (rivers, terrain, weather systems, fish); elements purposefully built by humans (transmission lines, electrical grids); cyber connections (both wired and Internet); and rules, regulations, and agreements at the federal, regional, state, and local levels.

Given the complexity of the NwHS and its context, it is instructive to analyze the NwHS by applying each of the four application paradigms of systems engineering presented in SEBok Part 4: the product, service, enterprise, and system-of-systems application paradigms.

Product System Provisioning

Product system provisioning applies systems engineering processes, methods, tools, and techniques to conceive, develop, and sustain the purposefully developed elements of a system (e.g., a hydro dam or a hydro system). In addition, some of the naturally occurring physical elements of a system may be shaped and configured (e.g., a river channel).

Major product elements of a hydro dam include the physical structure of the dam (including the spillway), the penstock (used to direct water into the turbines), the generating plant (i.e., the turbines used to turn generator rotors, generator stators and rotors that generate the electricity, step-up transformers used to increase the voltage level of electricity produced by the generators, and connections to transmission lines).

Cyber elements sense, measure, regulate, and control water flow, power generation, safety, security, and the structural integrity of the dam. Some turbines, for example, have adjustable vanes that are controlled to harvest maximum energy from the water, depending on the flow rate, power demand, and other factors. The cyber elements include: computing devices; supporting software (operating systems, databases, spreadsheets); data management software (collection, analysis, reporting); application software (displays of monitored status and interfaces for controlling operation of a dam); and communication interfaces to wired linkage and Internet-enabled links. In addition, software support is provided for the analog and digital devices needed to sense, measure, regulate, and control the purposefully built and naturally occurring elements of a dam and its environment.

Product system provisioning is also concerned with other issues that apply to individual dams, elements of dams, and the overall NwHS. They include issues such as: manufacturability/producibility; logistics and distribution; product

quality; product disposal; conformance to policies, laws, regulations, agreements, and standards; value added for stakeholders; and meeting customer's expectations. Many different technologies and engineering disciplines are needed to develop and sustain a hydro dam and the overall Northwest Hydro System. Product system provisioning can provide the coordination and control of systems engineering needed to develop, reconfigure, adapt, analyze, and sustain the hydro dams and the NwHS.

Service System Provisioning

A service is an activity performed by an entity to help or assist one or more other entities. Service system provisioning can be applied within the various contexts of services provided by the NwHS to meet stakeholders' requirements, users' needs, and system interactions with operators, users, and maintainers, plus the interactions with the contextual elements that determined services provided by the NwHS in the social, business, regulatory, and physical environments.

The NWHS provides electricity to a grid that serves commercial, industrial, governmental, and domestic customers. Stakeholders in addition to customers served include those who affect or will be affected by development, operation, and sustainment of a dam. Downstream stakeholders served, for example, include:, Native Americans, farmers and ranchers, and communities that receive the service of water released by the dam.

Additional service attributes include: the services that enable operators and maintainers to efficiently and effectively operate and maintain the physical and cyber elements of a dam; release water from the dam in a manner that services the upstream and downstream ecosystems; manage sharing of electrical power with other regional grids; provide emergency responses to power demands that result from electrical brownouts, blackouts, and overloads; and handle system failures that might be caused by earthquakes, terrorist attacks, and other catastrophic events.

Enterprise System Provisioning

An enterprise, such as the NwHS, consists of one or more organizations that share a mission, goals, and objectives to offer an output such as a product or service. The mission and goals of the NwHS are to provide most of the Northwest's firm energy needs and to maximize non-firm energy production while serving stakeholders and preserving affected environmental ecosystems. To meet those goals, the Northwest Hydroelectric Association (NWHA) coordinates the planning, design, improvement, and operation of the hydro dams that constitute the NwHS enterprise.

NWHA members represents all segments of the hydropower industry – independent developers and energy producers; public and private utilities; manufacturers and distributors; and local, state and regional governments including water and irrigation districts. Other NWHA members include contractors, Native American tribes, and consultants: engineers, financiers, environmental scientists, attorneys and others (NWHA 2016).

Note that an enterprise may consist of multiple organizations that are engaged in a common endeavor. The NwHS is a large complex enterprise that has many constituent organizations; namely, the organizations that own and operate the hydro dams and the other stakeholder members of the NWHA. Differences in ownership, structure, location, and size of hydro dams, the special interests of various NWHA members, and a complicated regulatory process, are some of the distinguishing characteristics of the NwHS that can be analyzed by enterprise systems provisioning.

System of Systems Provisioning

Many systems are composed of autonomous elements that are combined to provide increased capabilities that cannot be provided by the elements operating in isolation. The Northwest Hydro System is a system of systems comprised of autonomous hydro dams that have different owners, different operators, different stakeholders, and different regulators. The autonomous hydro dams could not provide the NwHS capabilities without the overall coordination and control that can be managed by applying system of systems provisioning.

Lessons Learned

NwHS is a collection of many interrelated ongoing projects that have shared common goals and shared constraints. The unique characteristics of NwHS make it a useful case study to illustrate how the four provisioning paradigms in SEBoK Part 4 provide essential viewpoints for analyzing large complex systems comprised of loosely coupled, autonomous elements.

Product systems engineering allows the collection of physical and purposefully built NwHS elements and their interconnections to be analyzed by applying systems product engineering processes and methods.

Service systems engineering supports analysis of the NwHS services provided to customers, users, farmers, ranchers, Native Americans, and other stakeholders who rely on NwHS for those services.

Enterprise systems engineering considers the broad scope and impact of the NwHS enterprise, both positive and negative, on the northwestern United States within the context of economic, social, physical, and regulatory environments.

System of Systems engineering applies the principles of planning, coordination, and operation to a collection of semi-autonomous hydro dams that form the Northwest Hydro System. The complexity of adding new dams as well as modifying and decommissioning existing dams in a seamless manner can best be understood by applying system of systems engineering processes and methods.

Taken together, the four provisioning paradigms in SEBoK Part 4 present a comprehensive view of a very large complex system whose many dimensions would be otherwise difficult, if not impossible, to comprehend when the NwHS is examined using only one of the paradigms.

Singapore Water Management

- Lead Authors:
- Heidi Davidz, Alex Lee, and Alice Squires
- Contributing Author:
- Richard Turner

-

This example was produced as a SE example directly for the SEBoK. It describes a systems engineering approach in the development of a sustainable National Water Management System for the Republic of Singapore. It demonstrates the successful outcome of long-term planning and a systems approach to preempt a critical water shortage. The example is primarily based on information taken from a paper presented at the INCOSE International Symposium in 2008. (Chia 2008.)

Description

When Singapore achieved independence in 1965, water supply depended on water catchment in local reservoirs and two bilateral water agreements with its closest neighbor, Malaysia. These water agreements are registered with the United Nations. The first agreement expired in August 2011, and the second agreement will expire in 2061 (Singapore 2012). After several failed attempts to renegotiate the extension of the first water agreement, Singapore determined that it was necessary to achieve full water self-sufficiency by 2060 in case the second water agreement also could not be extended. An intermediate goal was to match the supply of the first water agreement before it expired. This was achieved in several ways. In 2001, the Public Utilities Board (PUB), the national water agency responsible for treating raw water in Singapore, was charged to also begin managing wastewater and stormwater, allowing for an integrated and holistic approach to water management.

This example examines Singapore's water management system from a large-scale systems engineering perspective, particularly focusing on the goals, boundaries (see Concepts of Systems Thinking), stakeholders (see Stakeholder Needs Definition), and complexities involved in this type of a national system. This approach illustrates how Systems Thinking (illustrated through causal loop diagrams) and other systems engineering tools may be used to understand systems complexities. Concepts and methodologies of learning organizations were applied to enable understanding of behavioral complexities. Lean thinking facilitated a long-term strategic philosophy, built on the premise of continuous improvements.

Perhaps more importantly, it shows that while systems engineering, especially the Systems Approach, is necessary for the conceptualization and planning of such a complex system, it is not sufficient for success. It is the systemic structures that have been put in place over decades, political will, leadership, people, and culture that make such tasks realizable.

The supply of water in Singapore is managed in totality. Collecting rainwater, purchasing water, and purifying water utilizing reverse osmosis and desalination were all considered. Approaches included even incentivizing consumers to change their habits by making drains and canals recreational areas to encourage the public not to dispose of waste in their drains. By managing sewage and drainage together with water, environmental considerations are taken into account as well. By carefully adjusting organizational boundaries, Singapore has managed to reduce silo thinking and parochial interests. The relationships between the industry innovators, government, suppliers and users, and technology innovators create opportunities for Singapore's water management. This demonstrates how multiple stakeholder interests can be combined to create a viable water management solution. Continuous improvements through the use of technology and elimination of waste, such as reducing water that is not accounted for in the system, help to assure the sustainability of an adequate supply of water for a growing Singapore population. The Singapore Water Management system is already in successful operation and is being studied by the Organization for Economic Co-operation and Development (OECD) and by other nations.

Summary

The supply of water in Singapore is managed in totality through a systems approach, i.e., water catchment, supply, sewage and drainage. The importance of relationships between the stakeholders is also recognized. Industry innovators, political leadership, suppliers, and consumers are all involved; the project has been able to incentivize this diverse group to work together for a common goal, i.e., assuring the sustainability of an adequate supply of water for Singapore into the future.

Utilizing systems engineering and taking into consideration the systemic structures and culture required have helped Singapore achieve its first milestone of supplying its own water resources by 2010. Singapore has been able to overcome the shortfall that would have come about with the expiry of the first water agreement with Malaysia in 2011.

Part 8: Emerging Knowledge

Emerging Knowledge

Contents of this Part

- Emerging Topics (Robert Cloutier)
- Emerging Research (Robert Cloutier and Arthur Pyster)
- Lead Authors:
- Robert Cloutier, Daniel DeLaurentis, and Ha Phuong Le
-

Like other portions of the SEBoK, the notion and content of Part 8 is evolving. Part 8 consists of two Knowledge Areas (KAs): Emerging Topics and Emerging Research.

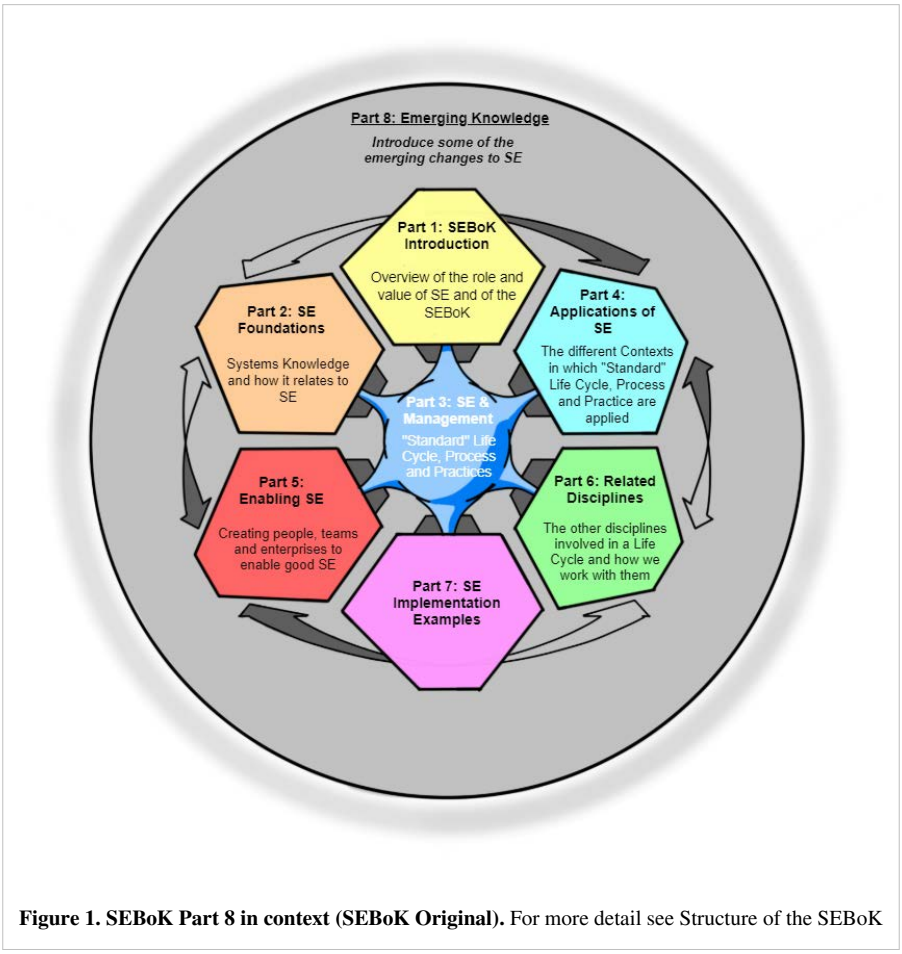

Figure 1. SEBoK Part 8 in context (SEBoK Original). For more detail see Structure of the SEBoK

Scope and Purpose

While the practice and need for systems engineering began appearing in journals from 1950 onward, the practice currently seems to be gaining momentum in most engineering and even non-engineering circles.

The classically trained systems engineers of the 1970s and even 1980s are faced with a C note shift in thinking brought on by the rapid advance of the software centricity of our systems, cybersecurity, agent-based, object-oriented, and model-based practices. These emerging practices bring their own methods and tools. Hall (1962, p. 5) may have been prescient when he wrote "It is hard to say whether increasing complexity is the cause or the effect of man's effort to cope with his expanding environment. In either case a central feature of the trend has been the development of large and very complex systems which tie together modern society. These systems include abstract or non-physical systems, such as government and the economic system."

These changes and the rate of change are causing systems engineering to evolve. Some of the practices may not even be recognizable to classically trained systems engineers. This Part of the SEBoK is intended to introduce some of the more significant emerging changes to systems engineering. As topics discussed in this Part evolve and become mainstream, they will be moved into the appropriate Part of the SEBoK.

System of Systems Engineering (SoSE) provides examples in recent times of an emerging topic from Systems Engineering community that generated emerging research, ultimately resulting in a foundational body of knowledge that continues to expand. A recent article describing this evolution from emerging topic to solution is now referenced in Part 4 - Systems of Systems (SoS).

Overview of Emerging Topics

See further: Emerging Topics

The Emerging Topics section is meant to inform the reader on the more significant and emerging changes to the practice of systems engineering. Examples of these emerging topics include:

- What is the potential to change systems engineering processes or the ways in which we perform systems engineering?
- How will the development of artificial intelligence impact systems engineering?
  - Will AI change the way we think of systems architecture?
  - How will we perform V&V of an AI system?
- How will the push towards vertically integrated digital engineering influence systems engineering?
- How are social features becoming more tightly connected to technical features of systems, and how is the modeling of socio-technical systems infusing into practice?

Overview of Emerging Research

See further: Emerging Research

As these emerging topics gain visibility, researchers will begin to investigate them. Corporate R&D may do early work, but academia and government will formalize this research. The Emerging Research section is a place to gather the references to this disparate work into a single repository to better inform systems engineers working on related topics. The references are collected from the following sources:

- PhD dissertations
- INCOSE publications and events
- IEEE publications and events
- Research funded by National Science Foundation (NSF) – Engineering Design and Systems Engineering (EDSE)
- Research funded by Systems Engineering Research Center (SERC)

The Emerging Topics section is intended to introduce and inform the reader on significant and rapidly emerging needs and trends in practicing systems engineering within the community. It is not intended to be all-inclusive. Instead, those topics that have a high probability of significantly impacting the practice of systems engineering, as determined by the SEBoK editorial board, are covered. If the reader has recommendations of emerging topics that should be covered, please send an email to SEBoK@incose.org, or leave a comment in the comment feature at the bottom of this page.

Introduction to Systems Engineering Transformation

The knowledge covered in this KA reflects the transformation and continued evolution of SE, which are formed by the current and future challenges (see Systems Engineering: Historic and Future Challenges). This notion of SE transformation and the other areas of knowledge which it includes are discussed briefly below.

The INCOSE Systems Engineering Vision 2035 (INCOSE 2021) describes the global context for SE, the current state of SE practice and the possible future state of SE. It describes a number of ways in which SE continues to evolve to meet modern system challenges. These are summarized briefly below.

Systems engineering has evolved from a combination of practices used in a number of related industries (particularly aerospace and defense). These have been used as the basis for a standardized approach to the life cycle of any complex system (see Systems Engineering and Management). Hence, SE practices are largely based on heuristics, with efforts under-way to evolve a theoretical foundation for systems engineering (see Foundations of Systems Engineering) considering foundational knowledge from a variety of sources.

Systems engineering continues to evolve in response to a long history of increasing system **complexity**. Such complexity arises from human and societal needs, global megatrends, grand engineering challenges, and then are shaped by stakeholders expectations, and the enterprise environment. System solutions require both depth and breadth, and the design of those solutions must consider both technical and social aspects (see Socio-technical Systems).

Many systems engineering practices have become standard (e.g. studies, risk analysis) while some other are in transitioning phase (e.g. Model-Based Systems Engineering, agile, systems-of-systems). More recently, the rise of Artificial Intelligence (AI) introduces unprecedented challenges in verification and validation of AI-infused systems, but also opens up new opportunities to implement AI methodologies in the design of systems.

Systems engineering has gained recognition across industries, academia and governments. However, SE practice varies across industries, organizations, and system types. Cross fertilization of systems engineering practices across industries has begun slowly but surely; however, the global need for systems capabilities has outpaced the progress in systems engineering.

INCOSE Vision 2035 concludes that SE is poised to play a major role in some of the global challenges of the 21st century, that it has already begun to change to meet these challenges and that it needs to undergo a more significant **transformation** to fully meet these challenges. The following bullet points are taken from the summary section of Vision 2035 and define the attributes of a transformed SE discipline in the future:

- The future of systems engineering is model-based, enabled by enterprise digital transformation.
- Systems engineering practices will make significant advancements to deal with systems complexity and enable enterprise agility.
- Systems engineering will leverage practices from other disciplines such as data science to help manage the growth in data.
- Formal systems engineering theoretical foundations will be codified leading to new research and development in the next generation of systems engineering methods and tools.
- AI will both impact the systems engineering practice and the types of systems designed by the systems engineering community.
- There will be a step change in systems engineering education starting with early education with a heavy focus on lifelong learning.

Some of these future directions of SE are covered in the SEBoK. Others need to be introduced and fully integrated into the SE knowledge areas as they evolve. This KA will be used to provide an overview of these transforming aspects of SE as they emerge. This transformational knowledge will be integrated into all aspects of the SEBoK as it matures.

Topics in Part 8

Introduction to SE Transformation

-

While the primary focus of the SEBoK is on the current practice of domain independent systems engineering, it is also concerned with the future evolution of the discipline.

The topics in this Knowledge Area (KA) summarize SE knowledge which is emerging and transitioning to become part of the practice of systems engineering, such as Model-Based Systems Engineering (MBSE). In general, topics will be introduced here and then expanded into other SEBoK KA's over time.

The knowledge covered in this KA reflects the transformation and continued evolution of SE. For a summary of the current and future challenges that contribute to this evolution, see Systems Engineering: Historic and Future Challenges. This notion of SE transformation and the other areas of knowledge which it includes are discussed briefly below.

Topics

Each part of the SEBoK is divided into Knowledge Areas (KAs), which are groupings of information with a related theme. The KAs, in turn, are divided into topics. This KA contains the following topics:

- Transitioning Systems Engineering to a Model-based Discipline
- Digital Engineering
- Set-Based Design
- Model-Based Systems Engineering Adoption Trends 2009-2018
- Systems Engineering Core Concepts

Systems Engineering Transformation

The INCOSE Systems Engineering Vision 2025 (INCOSE 2014) describes the global context for SE, the current state of SE practice and the possible future state of SE. It describes a number of ways in which SE continues to evolve to meet modern system challenges. These are summarized briefly below.

Systems engineering has evolved from a combination of practices used in a number of related industries (particularly aerospace and defense). These have been used as the basis for a standardized approach to the life cycle of any complex system (see Systems Engineering and Management). Hence, SE practices are still largely based on heuristics. Efforts are under-way to evolve a theoretical foundation for systems engineering (see Foundations of Systems Engineering) considering foundational knowledge from a variety of sources.

Systems engineering continues to evolve in response to a long history of increasing system complexity. Much of this evolution is in the models and tools focused on specific aspects of SE, such as understanding stakeholder needs, representing system architectures or modeling specific system properties. The integration across disciplines, phases of development, and projects continues to represent a key systems engineering challenge.

Systems engineering is gaining recognition across industries, academia and governments. However, SE practice varies across industries, organizations, and system types. Cross fertilization of systems engineering practices across industries has begun slowly but surely; however, the global need for systems capabilities has outpaced the progress in systems engineering.

INCOSE Vision 2025 concludes that SE is poised to play a major role in some of the global challenges of the 21st century, that it has already begun to change to meet these challenges and that it needs to undergo a more significant **transformation** to fully meet these challenges. The following bullet points are taken from the summary section of Vision 2025 and define the attributes of a transformed SE discipline in the future:

- Relevant to a broad range of application domains, well beyond its traditional roots in aerospace and defense, to meeting society's growing quest for sustainable system solutions to providing fundamental needs, in the globally competitive environment.
- Applied more widely to assessments of socio-physical systems in support of policy decisions and other forms of remediation.
- Comprehensively integrating multiple market, social and environmental stakeholder demands against "end-to-end" life-cycle considerations and long-term risks.
- A key integrating role to support collaboration that spans diverse organizational and regional boundaries, and a broad range of disciplines.
- Supported by a more encompassing foundation of theory and sophisticated model-based methods and tools allowing a better understanding of increasingly complex systems and decisions in the face of uncertainty.
- Enhanced by an educational infrastructure that stresses systems thinking and systems analysis at all learning phases.
- Practiced by a growing cadre of professionals who possess not only technical acumen in their domain of application, but who also have mastery of the next generation of tools and methods necessary for the systems and integration challenges of the times.

Some of these future directions of SE are covered in the SEBoK. Others need to be introduced and fully integrated into the SE knowledge areas as they evolve. This KA will be used to provide an overview of these transforming aspects of SE as they emerge. This transformational knowledge will be integrated into all aspects of the SEBoK as it matures.

Socio-technical Systems

- Lead Author:
- Erika Palmer

-

Though there are a few specific definitions, there are many ways in which the term “socio-technical system” is used depending on the specific engineering/scientific domain. There are also different approaches for considering socio-technical systems depending on the life cycle stage and the specific systems engineering challenge.

The Concept and Theory

The concept of a socio-technical system describes the interrelationship between humans and machines, and the motivation behind developing research on socio-technical systems was to cope with theoretical and practical work environment problems in industry (Ropohl, 1999).

Socio-technical systems theory has been developing over the past 60 years predominately focusing on new technology and work design (Davis et al., 2014). This theory has developed into socio-technical systems thinking, and research has concentrated in several key areas:

- Human factors and ergonomics (Carayon, 2006)
- Organizational design (Cherns, 1976)
- System design (Clegg, 2000; van Eijnatten, 1998)
- Information systems (Mumford, 2006)

A Design Approach

As a design approach ―socio-technical systems design (STSD)―socio-technical systems bring human, social, organizational and technical elements in the design of organizational systems (Baxter and Sommerville, 2011). While Baxter and Sommerville (2011) refer to computer-based systems in their definition of socio-technical systems thinking as a design approach, the generic term “technical system” is also applicable: “The underlying premise of socio-technical systems thinking is that system design should be a process that takes into account both social and technical factors that influence the functionality and usage of computer-based systems” (p.4).

Systems Engineering Context

In a systems engineering context, it has been argued that all systems are socio-technical systems (Palmer, et al., 2019). However, socio-technical systems in a systems engineering context is not well defined though the topic has gained traction in recent years (Donaldson, 2017; Broniatowski, 2018). There are examples in systems engineering literature, where the term socio-technical systems is used to refer to a system where social and technical elements are relevant. These include studies of agent-based modeling of socio-technical systems (Heydari and Pennock, 2018), insurance systems as socio-critical systems (Yasui, 2011) and interdisciplinary systems engineering approaches to influence enterprise systems (Pennock and Rouse, 2016; Wang et al., 2018).

Based on the work that the systems engineering community has produced thus far, the working definition of the term socio-technical systems in a systems engineering context is simply:

Socio-technical systems: Systems operating at the intersection of social and technical systems (Kroes et al., 2006).

Modeling Sociotechnical Systems

There is no "state of the practice" for how to model sociotechnical systems. There are, however, a few examples in systems engineering literature of how systems engineers could analyze these types of systems. Outside systems engineering/engineering literature, there is an ever-increasing number of examples of social system models. The modeling techniques found in these examples can be adapted to evaluate sociotechnical systems in a systems engineering context. Many of these are system dynamics models, and there is a journal dedicated to social system analysis, called the Journal for Artificial Societies and Social Simulation (JASS), which focuses on agent-based modeling.

1) Qualitative Modeling

- Insurance systems as socio-critical systems (Yasui, 2011)

Yasui (2011) provides a new methodology to accommodate stakeholder goals in social system failures. This new methodology is a "soft" systems approach that brings together the Holon concept by Checkland and Scholes (1990) and the Vee Model.

2) Agent-Based Modeling of Sociotechnical Systems in Systems Engineering

- Agent-based modeling of sociotechnical systems (Heydari and Pennock, 2018)

Heydari and Pennock (2018) illustrate how to support the design and governance of sociotechnical systems with agent-based modeling (ABM). Critically, they outline the difference between how ABM is used in physical, natural and social applications versus sociotechnical applications.

- Interdisciplinary systems engineering approaches to influence enterprise systems (Pennock and Rouse, 2016)

Pennock and Rouse (2016) not only provide how to define an enterprise as a system, but they also illustrate this with several ABM examples. They also highlight that when modeling sociotechnical systems versus traditional engineering systems, it is important to focused less on "control" and more on "influence."

3) Economic modeling

- Social System Modeling Challenges (Wang et al., 2018)

In their book, Social Systems Engineering, Wang et al. (2018) provide an overview of not only modeling and its challenges in evaluating social systems, but they also give insight into how social system modeling is approached in economics.

4) System Dynamics Modeling of Social Systems for Adaptation in an SE Sociotechnical Context

- Social policy (Palmer, 2017)

Palmer (2017) provides an overview of social systems in a systems engineering context, and uses system dynamics modeling of pension and sick leave policy systems to illustrate how to use systems engineering methods for social policy.

- Social Systems Engineering (García-Díaz and Olaya, 2018)

García-Díaz and Olaya (2018) give not only a thorough overview in their book (called Social Systems Engineering) of social systems and various qualitative and quantitative modeling types, but they also highlight participatory system dynamics modeling (stakeholder-led system design).

- Health care (Homer and Hirsch, 2006)

As there is increasing attention in the systems engineering community towards health care technology, Homer and Hirsch's (2006) paper on system dynamics modeling of public health gives a basis for how to model social systems

in this domain. For example, chronic disease prevention, disease outcomes, health and risk behaviors, environmental factors, and health-related resources and delivery systems.

Artificial Intelligence

- Lead Authors:
- Barclay Brown, Tom McDermott, Rael Kopace, Ramakrishnan Raman, Ali Raz, and Kevin Robinson

-

This article provides an overview and definitions of artificial intelligence and machine learning and their importance to and relationships with systems engineering.

Introduction

Artificial Intelligence (AI) is perhaps best defined as the ability of a system to exhibit behavior, which if exhibited by a human being, would be considered intelligent. It's the ability of a machine to process and learn from data, to recognize and understand patterns, to solve problems, and make decisions autonomously. The term "Artificial Intelligence" dates to the early 1950s where it was first introduced to mimic human-level intelligence capabilities in software and hardware systems—a goal which still is far from reachable in the near future despite the rapid technological advancement in the AI field . It is important for systems engineers to note that "AI" does not designate a specific technology—intelligent behavior can be implemented in a system in a number of ways, including conventional software or hardware logic. Modern systems that use AI fall into two major categories: systems where the decision-making logic is explicitly pre-programmed, and systems where the decision-making capability is learned from data. This latter category, known as Machine Learning (ML), is the predominant category for the modern paradigm shift in capabilities enabled by AI.

Machine Learning Foundations of AI

ML builds its foundation from statistics and computer science disciplines, accelerated by the advances in computational power and memory offered by modern hardware systems (i.e., CPUs and GPUs). The ever-increasing number of ML algorithms available today can be classified into three major categories of Supervised, Unsupervised, and Reinforcement learning.

- Supervised Learning is where labelled input-output datasets are available and ML algorithms learn the mapping between input-output pairs presented in the datasets (for example, learning from clearly labelled pictures of cars and tanks)
- Unsupervised Learning is where the labels in data sets are not available and the ML algorithms learn the grouping or clustering of input and outputs (for example, identifying common customer attributes, classifying spam email, or detecting fraudulent transactions)
- Reinforcement Learning is where an AI agent trains itself to make decisions to effect a positive change in the environment based on a defined reward function (e.g., training a robot to avoid obstacles by penalizing crashes)

The implementation approaches for all ML types require large datasets and can be based on statistical models or neural networks including Deep Neural Networks (DNNs). Irrespective of the implementation approaches and the type of ML, the workflow for deploying an ML-based AI solution remains largely common and is shown in Figure 1 (details on each of these steps can be found in the Digital Transformation book by Thomas Siebel).

Figure 1 A typical ML Workflow

Understanding the subtleties of statistical models and neural networks for ML implementation along with the related workflow will become imperative for systems engineers as they begin to incorporate ML solutions in systems and perform systems engineering activities for AI systems.

Systems Engineers and AI

Given the holistic nature of the systems engineering discipline, it is practical to think about AI and its role in the larger context of digital transformation, which can be defined as the confluence of big data, cloud computing, AI and Internet of Things (IoT). Digital transformation is enabling organizations to evolve their business and operational models. As such most organizations are collecting vast amounts of data pertaining to their business, operations, systems, customers, and personnel. Big data has created the conditions that necessitate the application of AI solutions supported by the technological advancements in computational power and memory to aid in the analysis of big data and the automation of labor intensive and time-consuming processes.

The ability to collaborate and communicate with data scientists, AI engineers, cloud computing specialists, application developers, and other experts is becoming a necessity for many systems engineers. Systems engineers must become sufficiently knowledgeable and familiar with as many elements of the digital transformation ecosystem as possible to best serve the needs of the organization and its mission in order to identify the areas of business or the systems that would most benefit from the application of AI. Understanding the benefits as well as the potential pitfalls of an AI development initiatives is also important. To that end, systems engineers must be able to identify the right requirements and architectures, expertise, partnering organizations, technology stack, development platforms, and other relatable elements. The roles and responsibilities of systems engineers versus data scientists, data engineers, application developers, and AI engineers must be differentiated. The market is filled with an ever-growing number of AI platforms and it is virtually impossible for a non-data scientist to be able to master each of them. Moreover, the advances in the AI domain happen at such a rapid pace that nowadays many companies may choose to avoid investing in their own internal data science teams to develop AI solutions. Instead, they can purchase or license models that are ready for implementation from companies that have solved similar problems before. Additionally, there exist unified platforms that aim to standardize workflows and come equipped with the appropriate technology stack to collect, label, and feed data into supervised learning models or alternatively assist with the development of models.

As a result, rather than mirroring the roles and responsibilities of data scientists and other AI domain professionals, it is beneficial for most systems engineering professionals to develop an understanding at various degrees of depth of the relevant technologies that support and are used to create AI applications including but not limited to the following:

- Data integration
- Relational and non-relational databases
- Cloud storage
- Enterprise architecture infrastructure and APIs
- ML learning frameworks
- Batch and online processing
- Executable environments
- Commonly used programming languages
- UI and data visualization tools

Systems Engineering and AI: SE4AI and AI4SE

At an early 2019 Future of Systems Engineering (FuSE) workshop hosted by the International Council on Systems Engineering (INCOSE), the terms AI for SE and SE for AI were first used to describe the dual transformation envisioned for both the SE and AI disciplines. The "AI4SE" and "SE4AI" labels have quickly become symbols for an upcoming rapid evolutionary phase in the SE community. SE's Digital Engineering transformation will enable both transformation of SE practices using AI for SE and drive the need for new systems engineering practices that support a new wave of automated, adaptive, and learning systems, termed SE for AI. AI4SE applies AI and ML techniques to improve human-driven engineering practices. This goal of "augmented intelligence" includes outcomes such as achieving scale in model construction and efficiency in designing space exploration systems. SE4AI applies SE methods to the design and operation of intelligent systems, with outcomes such as improved safety, security, ethics, etc.

Systems engineers have long sought to evolve engineered systems to include human-like intelligence, thinking, and autonomous decision-making. In many cases, the inclusion of intelligent capabilities means increasing non-determinism in the system's behavior, exponentially increasing complexity in the design, verification, and validation of such systems. The initial approaches of inculcating intelligence predominantly involved human-in-the-loop for capturing knowledge from experts, codifying it in some form that is machine understandable (for instance, a "knowledge database"), and enabling the system to interpret the codified knowledge so as to make the required optimal decisions and exhibit the desired intelligent behavior. These initial approaches involved human-in-the loop for the entire gamut of activities from capturing the knowledge and codifying the knowledge to enabling (programming) the system to leverage the knowledge.

More recent contemporary approaches represent the next evolution of inculcating intelligence in systems, wherein the human gathers the required data and programs the system such that the system can learn/build the knowledge from the data provided by the human. Learning from data requires significant computing resources (processing power and memory) but recent advances have expanded the availability of large amounts of both source data and matching computing resources to enable intensive processing and learning from data. Recent ML algorithms are the result of this evolution. The system learns during the design and development phases and is expected to demonstrate limited forms of adaptive behavior.

In both approaches, a human is in the loop to validate the intelligence gained by the system, and to make a conscious decision to deploy the intelligence in the system. The next evolution is expected to be predominantly based on a system learning from the other systems it interacts with (machine-to-machine learning) and building its intelligence from the interactions and from the ecosystem (cloud). Evolution in that direction is as seen by some of the recent progress made in reinforcement learning models and algorithms. The system learns by trial-and-error and once it meets performance expectations, can apply its behavior on a larger scale.

The augmented intelligence scenarios described above will need an underlying and synergistic foundation of both SE4AI and AI4SE which are briefly described in the following subsections.

SE4AI: Addressing Practical Implementation Challenges for AI

The increasing application of AI in systems presents challenges for both the systems engineering community and the AI community. Their common goal is to ensure that the future users of the system can be certain that the behavior and performance of that system is what is needed. That is, the AI system's behavior is verified through a set of activities that check its compliance against system requirements and validate it for fitness to meet user needs. The need for verification and validation presents a challenge for the engineering of AI systems as the failure modes observed in AI systems are different and may not be adequately addressed by traditional Systems Engineering life-cycle approaches. From a systems engineering lifecycle perspective, appropriate tailoring of conventional processes is needed to "engineer" a system that is intelligent—a system that learns during development and is designed for adaptive behavior. New approaches are required for developing requirements, evaluating when these

intelligent systems are ready for operations, and for ensuring their adaptive behavior is safe and produces the desired outcomes. The data required for enabling a system to acquire the desired intelligence poses several challenges from being biased (inculcating a biased intelligence reflected in the system's behavior) to not being representative of the various use case scenarios envisaged for the system. The system's intelligence is only as good as the data that was used to train it. There are many considerations pertaining to the broader challenge of engineering safe and effective human interaction with intelligent systems. These include (a) leveraging cognitive strengths of humans and AI, (b) gaining trust, (c) explainable intelligence (d) identifying and understanding bias, and (e) dealing with uncertainty.

Broadly there are three key challenges for the systems engineering of intelligent systems:

1. **New failure modes not previously experienced in the engineering of systems.** The AI community recognizes that there are there are five main failure modes that cause the AI systems to not behave safely and as expected. These new failure modes include negative side effects, reward hacking, scalable oversight, unsafe exploration, and distributional shift .
2. **The unpredictability of performance due to non-deterministic and evolving behavior.** ML systems initially learn from predetermined data and through the activity of validation, system engineers check the compliance of the system performance against its intended purpose, captured in a Systems Specification. The challenge with AI, and specifically ML, is predicting the performance and behaviour of the AI algorithm on unseen data in future operations. ML systems exhibit non-deterministic performance, with the performance of some systems evolving as the system learns (changes performance) during operations. This presents challenges in validating system compliance before the system enters operations.
3. **Lack of trust and robustness in future systems performance.** System validation is based on a basic four step approach: obtaining results from a validation test, comparing the measured results to expect results, deducing the degree of compliance, and deciding on the acceptability of this compliance. A key aspect in deciding the acceptability of compliance is expert judgement. Expert judgement requires an understanding of the result as compared to the relevance of the context of use, and therefore the results need to be explainable. Explainable behaviour of AI Systems is problematic, and therefore determining a level of trust and robustness in future systems performance is challenging.

AI4SE: Leveraging AI to Advance State-of-the-Art in Systems Engineering

The next evolution of SE practices is expected to be predominantly driven by AI technologies assisting systems engineers in the engineering development lifecycle activities. AI4SE addresses how AI can enhance the systems engineering lifecycle for engineered systems, across the various lifecycle phases including concept development, requirements, architecture design, implementation, integration, verification, validation, and deployment. Enhancing and assisting systems engineering processes, methods, and tools, with tangible impacts on the quality of the engineered system as well as on the cycle time for the various life cycle activities, would be some of the primary focus areas of AI4SE. For instance, AI technologies can be leveraged to advise system architects on the various architecture and design decisions options based on intelligence built from collective prior experience of decisions made in earlier systems. A second example is leveraging AI technologies to assist in arriving at various corner test cases during verification. Historical systems engineering life cycle data would be the predominant drivers for the use of AI for such applications. A third example would pertain to the simulation aspects, where digital and synthetic environments (e.g., digital twins) are leveraged to understand various lifecycle operation scenarios and providing better insights to systems engineers on understanding the implications of architecture design decisions on the engineered systems. However, some forms of distinction are being envisaged in the community between AI4SE as against automation, digitization and digital linking of various SE life cycle artifacts and work products. While automation and digitization activities may be enhanced by AI, these activities may still be dominated by conventional software, with outcomes focused on significant reduction in life cycle time and efficiency on managing scale.

Landscape of AI Applications in Industry and Systems

Over the last few decades, ML-based solutions have become ubiquitous in technical and social systems and have enabled new business opportunities and even new business models. The rapid commercialization of AI is bringing profound changes to all markets. Capabilities are advancing and it is becoming easier to develop and implement AI solutions given the growing number of AI tools and platforms. Organizations in every industry segment are increasingly realizing that AI is key to market leadership and that they all have processes that are suited for AI. Early adopters of AI have noticed significant tangible benefits and given the lower barriers of entry that exist nowadays, others are making significant investments to accelerate their AI adoption.

AI is being integrated into the fabric of business and systems and AI solutions are being deployed to solve a wide spectrum of use cases at every layer of the enterprise. The following table provides examples of AI applications across the different fields and sectors.

Domain	General examples of AI usage
Sales	Price optimization, forecasting, performance management, dynamic recommendations (think Amazon, Netflix making product and movie recommendations) [Ref: https://hbr.org/2018/07/how-ai-is-changing-sales]
Security	Breach risk prediction, incident response, early identification and classification of cyber threats [Ref: https://www.ibm.com/case-studies/cargills-bank-ltd]
Anti-fraud	Identification of fraudulent behavior and transactions [Ref: https://www.fico.com/blogs/5-keys-using-ai-and-machine-learning-fraud-detection]
HR	Candidate assessment, screening time reduction, skills to jobs alignment [Ref: https://www.forbes.com/sites/jeannemeister/2019/01/08/ten-hr-trends-in-the-age-of-artificial-intelligence/?sh=426c0c7d3219]

Verification and Validation of Systems in Which AI is a Key Element

- Lead Author:
- Laura Pullum

-

Many systems are being considered in which artificial intelligence (AI) will be a key element. Failure of an AI element can lead to system failure (Dreossi et al 2017), hence the need for AI verification and validation (V&V). The element(s) containing AI capabilities is treated as a subsystem and V&V is conducted on that subsystem and its interfaces with other elements of the system under study, just as V&V would be conducted on other subsystems. That is, the high-level definitions of V&V do not change for systems containing one or more AI elements.

However, AI V&V challenges require approaches and solutions beyond those for conventional or traditional (those without AI elements) systems. This article provides an overview of how machine learning components/subsystems "fit" in the systems engineering framework, identifies characteristics of AI subsystems that create challenges in their V&V, illuminates those challenges, and provides some potential solutions while noting open or continuing areas of research in the V&V of AI subsystems.

Overview of V&V for AI-based Systems

Conventional systems are engineered via 3 overarching phases, namely, requirements, design and V&V. These phases are applied to each subsystem and to the system under study. As shown in Figure 1, this is the case even if the subsystem is based on AI techniques.

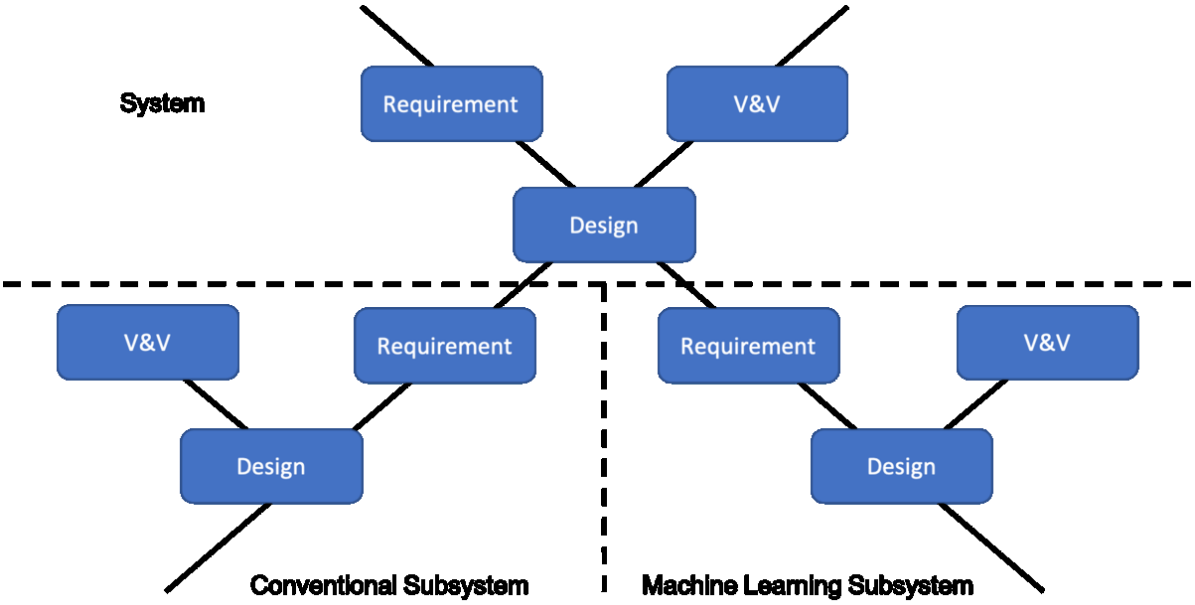

Figure 1. Systems Engineering Phases for Systems Containing Machine Learning and Conventional Subsystems. (SEBoK Original, modeled after (Kuwajima et al. 2020))

AI-based systems follow a different lifecycle than do traditional systems. As shown in the general machine learning life cycle illustrated in Figure 2, V&V activities occur throughout the life cycle. In addition to requirements allocated to the AI subsystem (as is the case for conventional subsystems), there also may be requirements for data that flow up to the system from the AI subsystem.

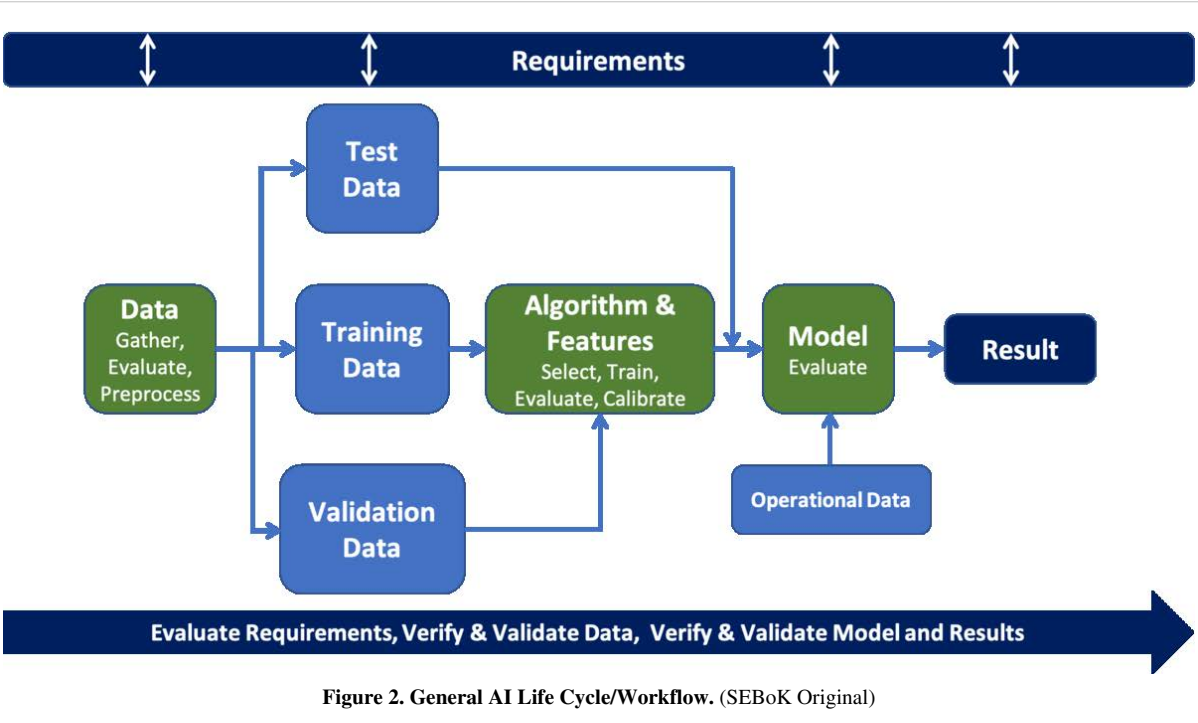

Figure 2. General AI Life Cycle/Workflow. (SEBoK Original)

Characteristics of AI Leading to V&V Challenges

Though some aspects of V&V for conventional systems can be used without modification, there are important characteristics of AI subsystems that lead to challenges in their verification and validation. In a survey of engineers, Ishikawa and Yoshioka (2019) identify attributes of machine learning that make the engineering of same difficult. According to the engineers surveyed, the top attributes with a summary of the engineers' comments are:

- *Lack of an oracle*: It is difficult or impossible to clearly define the correctness criteria for system outputs or the right outputs for each individual input.
- *Imperfection*: It is intrinsically impossible to for an AI system to be 100% accurate.
- *Uncertain behavior for untested data*: There is high uncertainty about how the system will behave in response to untested input data, as evidenced by radical changes in behavior given slight changes in input (e.g., adversarial examples).
- *High dependency of behavior on training data*: System behavior is highly dependent on the training data.

These attributes are characteristic of AI itself and can be generalized as follows:

- Erosion of determinism
- Unpredictability and unexplainability of individual outputs (Sculley et al., 2014)
- Unanticipated, emergent behavior, and unintended consequences of algorithms
- Complex decision making of the algorithms
- Difficulty of maintaining consistency and weakness against slight changes in inputs (Goodfellow et al., 2015)

V&V Challenges of AI Systems

Requirements

Challenges with respect to AI requirements and AI requirements engineering are extensive and due in part to the practice by some to treat the AI element as a "black box" (Gunning 2016). Formal specification has been attempted and has shown to be difficult for those hard-to-formalize tasks and requires decisions on the use of quantitative or Boolean specifications and the use of data and formal requirements. The challenge here is to design effective methods to specify both desired and undesired properties of systems that use AI- or ML-based components (Seshia 2020).

A taxonomy of AI requirements engineering challenges, outlined by Belani and colleagues (2019), is shown in Table 1.

Table 1: Requirements engineering for AI (RE4AI) taxonomy, mapping challenges to AI-related entities and requirements engineering activities (after (Belani et al., 2019))

RE4AI	AI Related Entities		
RE Activities	**Data**	**Model**	**System**
Elicitation	- Availability of large datasets - Requirements analyst upgrade	- Lack of domain knowledge - Undeclared consumers	- How to define problem /scope - Regulation (e.g., ethics) not clear
Analysis	- Imbalanced datasets, silos - Role: data scientist needed	- No trivial workflows - Automation tools needed	- No integration of end results - Role: business analyst upgrade
Specification	- Data labelling is costly, needed - Role: data engineer needed	- No end-to-end pipeline support - Minimum viable model useful	- Avoid design anti- patterns - Cognitive / system architect needed
Validation	- Training data critical analysis - Data dependencies	- Entanglement, CACE problem - High scalability issues for ML	- Debugging, interpretability - Hidden feedback loops

Management	- Experiment management	- Difficult to log and reproduce	- IT resource limitations, costs
	- No GORE-like method polished	- DevOps role for AI needed	- Measuring performance
Documentation	- Data & model visualization	- Datasets and model versions	- Feedback from end-users
	- Role: research scientist useful	- Education and training of staff	- Development method
All of the Above	- Data privacy and data safety		
	- Data dependencies		

CACE: change anything, change everything

GORE: goal-oriented requirements engineering

Data

Data is the life-blood of AI capabilities given that it is used to train and evaluate AI models and produce their capabilities. Data quality attributes of importance to AI include accuracy, currency and timeliness, correctness, consistency, in addition to usability, security and privacy, accessibility, accountability, scalability, lack of bias and others. As noted above, the correctness of unsupervised methods is embedded in the training data and the environment.

There is a question of coverage of the operational space by the training data. If the data does not adequately cover the operational space, the behavior of the AI component is questionable. However, there are no strong guarantees on when a data set it 'large enough'. In addition, 'large' is not sufficient. The data must sufficiently cover the operational space.

Another challenge with data is that of adversarial inputs. Szegedy et al. (2014) discovered that several ML models are vulnerable to adversarial examples. This has been shown many times on image classification software, however, adversarial attacks can be made against other AI tasks (e.g., natural language processing) and against techniques other than neural networks (typically used in image classification) such as reinforcement learning (e.g., reward hacking) models.

Model

Numerous V&V challenges arise in the model space, some of which are provided below.

- *Modeling the environment*: Unknown variables, determining the correct fidelity to model, modeling human behavior. The challenge problem is providing a systematic method of environment modeling that allows one to provide provable guarantees on the system's behavior even when there is considerable uncertainty about the environment. (Seshia 2020)
- *Modeling learning systems*: Very high dimensional input space, very high dimensional parameter or state space, online adaptation/evolution, modeling context (Seshia 2020).
- *Design and verification of models and data*: data generation, quantitative verification, compositional reasoning, and compositional specification (Seshia 2020). The challenge is to develop techniques for compositional reasoning that do not rely on having complete compositional specifications (Seshia 2017).
- *Optimization strategy must balance between over- and under-specification*. One approach, instead of using distance (between predicted and actual results) measures, uses the cost of an erroneous result (e.g., an incorrect classification) as a criterion (Faria, 2018) (Varshney, 2017).
- *Online learning*: requires monitoring; need to ensure its exploration does not result in unsafe states.
- *Formal methods*: intractable state space explosion from complexity of the software and the system's interaction with its environment, an issue with formal specifications.
- *Bias* in algorithms from underrepresented or incomplete training data OR reliance on flawed information that reflects historical inequities. A biased algorithm may lead to decisions with collective disparate impact. Trade-off between fairness and accuracy in the mitigation of an algorithm's bias.

- *Test coverage*: effective metrics for test coverage of AI components is an active area of research with several candidate metrics, but currently no clear best practice.

Properties

Assurance of several AI system properties is necessary to enable trust in the system, e.g., the system's trustworthiness. This is a separate though necessary aspect of system dependability for AI systems. Some important properties are listed below and though extensive, are not comprehensive.

- *Accountability*: refers to the need of an AI system to be answerable for its decisions, actions and performance to users and others with whom the AI system interacts
- *Controllability*: refers to the ability of a human or other external agent to intervene in the AI system's functioning
- *Explainability*: refers to the property of an AI system to express important factors influencing the AI system results or to provide details/reasons behind its functioning so that humans can understand
- *Interpretability*: refers to the degree to which a human can understand the cause of a decision (Miller 2017)
- *Reliability*: refers to the property of consistent intended behavior and results
- *Resilience*: refers to the ability of a system to recover operations quickly following an incident
- *Robustness*: refers to the ability of a system to maintain its level of performance when errors occur during execution and to maintain that level of performance given erroneous inputs and parameters
- *Safety*: refers to the freedom from unacceptable risk
- *Transparency*: refers to the need to describe, inspect and reproduce the mechanisms through which AI systems make decisions, communicating this to relevant stakeholders.

V&V Approaches and Standards

V&V Approaches

Prior to the proliferation of deep learning, research on V&V of neural networks touched on adaptation of available standards, such as the then-current IEEE Std 1012 (Software Verification and Validation) processes (Pullum et al. 2007), areas need to be augmented to enable V&V (Taylor 2006), and examples of V&V for high-assurance systems with neural networks (Schumann et al., 2010). While these books provide techniques and lessons learned, many of which remain relevant, additional challenges due to deep learning remain unsolved.

One of the challenges is data validation. It is vital that the data upon which AI depends undergo V&V. Data quality attributes that are important for AI systems include accuracy, currency and timeliness, correctness, consistency, usability, security and privacy, accessibility, accountability, scalability, lack of bias, and coverage of the state space. Data validation steps can include file validation, import validation, domain validation, transformation validation, aggregation rule and business validation (Gao et al. 2011).

There are several approaches to V&V of AI components, including formal methods (e.g., formal proofs, model checking, probabilistic verification), software testing, simulation-based testing and experiments. Some specific approaches are:

- Metamorphic testing to test ML algorithms, addressing the oracle problem (Xie et al., 2011)
- A ML test score consisting of tests for features and data, model development and ML infrastructure, and monitoring tests for ML (Breck et al., 2016)
- Checking for inconsistency with desired behavior and systematically searching for worst-case outcomes when testing consistency with specifications.
- Corroborative verification (Webster et al., 2020), in which several verification methods, working at different levels of abstraction and applied to the same AI component, may prove useful to verification of AI components of systems.

- Testing against strong adversarial attacks (Useato, 2018); researchers have found that models may show robustness to weak adversarial attacks and show little to no accuracy to strong attacks (Athalye et al., 2018, Uesato et al., 2018, Carlini and Wagner, 2017).
- Use of formal verification to prove that models are consistent with specifications, e.g., (Huang et al., 2017).
- Assurance cases combining the results of V&V and other activities as evidence to support claims on the assurance of systems with AI components (Kelly and Weaver, 2004; Picardi et al. 2020).

Standards

Standards development organizations (SDO) are earnestly working to develop standards in AI, including the safety and trustworthiness of AI systems. Below are just a few of the SDOs and their AI standardization efforts.

ISO is the first international SDO to set up an expert group to carry out standardization activities for AI. Subcommittee (SC) 42 is part of the joint technical committee ISO/IEC JTC 1. SC 42 has a working group on foundational standards to provide a framework and a common vocabulary, and several other working groups on computational approaches to and characteristics of AI systems, trustworthiness, use cases, applications, and big data. (https://www.iso.org/committee/6794475.html)

The IEEE P7000 series of projects are part of the IEEE Global Initiative on Ethics of Autonomous and Intelligent Systems, launched in 2016. IEEE P7009, "Fail-Safe Design of Autonomous and Semi-Autonomous Systems" is one of 13 standards in the series. (https://standards.ieee.org/project/7009.html)

Underwriters Laboratory has been involved in technology safety for 125 years and has released ANSI/UL 4600 "Standard for Safety for the Evaluation of Autonomous Products". (https://ul.org/UL4600)

The SAE G-34, Artificial Intelligence in Aviation, Committee is responsible for creating and maintaining SAE Technical Reports, including standards, on the implementation and certification aspects related to AI technologies inclusive of any on or off-board system for the safe operation of aerospace systems and aerospace vehicles. (https://www.sae.org/works/committeeHome.do?comtID=TEAG34)

Transitioning Systems Engineering to a Model-based Discipline

-

Systems engineers have always leveraged many kinds of models, including functional models to support requirements development, simulation models to analyze the behavior of systems, and other analytical models to analyze various aspects of the system such as reliability, safety, mass properties, power consumption, and cost. However, the discipline still relies heavily on document-based artifacts to capture much of the system specification and design information, such as requirements, interface control documentation, and system architecture design descriptions. This information is often spread across many different documents including text, informal drawings, and spreadsheets. This document-based approach to systems engineering suffers from a lack of precision, inconsistencies from one artifact to another, and difficulties in maintaining and reusing the information.

Model-Based Systems Engineering

Model-based systems engineering (MBSE) is the formalized application of modeling to support system requirements, design, analysis, verification, and validation activities beginning in the conceptual design phase and continuing through development and later life cycle phases (INCOSE 2007). A distinguishing characteristic of an MBSE approach is that the model constitutes a primary artifact of the systems engineering process. The focus on developing, managing and controlling a model of the system is a shift from the traditional document-based approach to systems engineering, where the emphasis is on producing and controlling documentation about the system. By leveraging the system model as a primary artifact, MBSE offers the potential to enhance product quality, enhance reuse of the system modeling artifacts, and improve communications among the systems development team. This, in turn, offers the potential to reduce the time and cost to integrate and test the system, and significantly reduce cost, schedule, and risks in fielding a system.

MBSE includes a diverse set of descriptive and analytical models that can be applied throughout the life cycle, and from system of systems (SoS) modeling down to component modeling. Typical models may include descriptive models of the system architecture that are used to specify and design the system, and analytical models to analyze system performance, physical characteristics, and other quality characteristics such as reliability, maintainability, safety, and cost.

MBSE has been evolving for many years. The term MBSE was used by Wayne Wymore in his book by this name (Wymore 1993), that provided a state-based formalism for analyzing systems in terms of their input/output characteristics, and value functions for assessing utility of technology independent and technology dependent systems. Simulations have been extensively used across industry to provide high fidelity performance analysis of complex systems. The Standard for Integration Definition for Function Modeling (IDEF0 1993) was introduced in the 1990's to support basic functional modeling. A modeling formalism called the enhanced functional flow block diagram (Long 2000) has been used to model many different types of systems. The Object Management Group

(OMG) introduced the concept of a Model Driven Architecture (MDA®) (OMG 2003) that leverages a standards-based approach to modeling. The Systems Modeling Language (OMG SysML™) (OMG 2015) was adopted by the OMG in 2006 as a general-purpose systems modeling language. In addition, the Unified Profile for DoDAF and MODAF (UPDM) (OMG 2013) was adopted by the OMG in 2008 to support enterprise modeling. Several other domain specific modeling languages have been introduced as well.

MBSE Transition

The INCOSE Systems Engineering Vision 2025 (INCOSE 2025, pg 38) describes the current state of MBSE as follows: “Model-based systems engineering has grown in popularity as a way to deal with the limitations of document-based approaches, but is still in an early stage of maturity similar to the early days of CAD/CAE.”

SE Vision 2025 also describes a continuing transition of SE to a model-based discipline in which: “Formal systems modeling is standard practice for specifying, analyzing, designing, and verifying systems, and is fully integrated with other engineering models. System models are adapted to the application domain, and include a broad spectrum of models for representing all aspects of systems. The use of internet driven knowledge representation and immersive technologies enable highly efficient and shared human understanding of systems in a virtual environment that span the full life cycle from concept through development, manufacturing, operations, and support.” The transition to a more model-based discipline is not without its challenges. This requires both advancements in the practice, and the need to achieve more widespread adoption of MBSE within organizations across industry sectors.

The INCOSE Systems Engineering Vision 2035 (INCOSE 2035, pg 33) states that "The Future of Systems Engineering Is Predominantly Model-Based". Further discussion goes on to project that "Systems engineers routinely compose task-specific virtual models using ontologically linked, digital twin-based model-assets. These connected models are updated in real-time providing a virtual reality-based, immersive design and exploration space. This virtual global collaboration space is cloud- based, enabled by modelling as a service and supports massive simulation leveraging cloud-based high-capacity compute infrastructure. Families of unified ModSim frameworks exist enabling small and medium businesses along with Government agencies to collaborate."

Advancing the practice requires improvements in the modeling languages, methods, and tools. The modeling languages must continue to improve in terms of their expressiveness, precision, and usability. MBSE methods, such as those highlighted in A Survey of Model-Based Systems Engineering (MBSE) Methodologies (Estefan 2008), have continued to evolve, but require further advancements to provide a rigorous approach to modeling a system across the full system lifecycle, while being more adaptable to a diverse range of application domains. The modeling tools must also continue to evolve to support the modeling languages and methods, and to integrate with other multi-disciplinary engineering models and tools in support of the broader model-based engineering effort. The movement towards increased use of modeling standards, that are more widely available in commercial tools, and rigorous model-based methodologies, increase the promise of MBSE.

The adoption of MBSE requires a workforce that is skilled in the application of MBSE. This requires organizations to provide an infrastructure that includes MBSE methods, tools, and training, and a commitment to deploy this capability to their programs. As with any organizational change, this must be approached strategically to grow this capability and learn from their experiences.

Like other engineering disciplines, the transition of systems engineering to a model-based discipline is broadly recognized as essential to meet the challenges associated with increasing system complexity and achieving the productivity and quality improvements. The SEBoK will continue to reflect the growing body of knowledge to facilitate this transition.

Model-Based Systems Engineering Adoption Trends 2009-2018

- Lead Author:
- Rob Cloutier
- Contributing Author:
- Ifezue Obiako

-

The MBSE Initiative was kicked off at the INCOSE International Workshop (IW) in 2007 at the Albuquerque, NM, USA Embassy Suites. There were approximately 45 INCOSE members for this first meeting, held during the two days preceding IW.

Surveys were conducted in 2009, 2012, 2014, 2018, and 2019 to better understand the adoption trends of model-based systems engineering.

Introduction

Model-based systems engineering (MBSE) is not a new concept. Wymore (1993) published the seminal work on the topic. This book presents the mathematical theory behind MBSE. Since that time, engineering has made significant movement from text-based approaches using office-based tools (e.g. Harvard Graphics, Microsoft PowerPoint, Microsoft Visio, etc.) to an interconnected set of graphical diagrams. These diagrams are generally created in a tool with a specialized graphical user interface.

Today aerospace engineers no longer use drafting boards to create their drawings – they use computer aided design (CAD) tools. Likewise, software engineers seldom use EMACS or Vi (text editors), instead, they use software GUIs that allow them to code, check syntax, compile, link, and run their software all in a single environment.

Broadly speaking, a model_ can be thought of as a facsimile or abstraction of reality. To this end, even a requirements document can be considered a model – it represents what a real system should do in performing its mission or role. While systems engineering has used models for a very long time, MBSE is the systems engineering migration to computer-based graphical user interfaces to perform our analysis and design tasks just as our other engineering brethren have moved to computer-based graphical user interfaces.

A discussion of available tools is beyond the scope of this article, and it is not the practice of the SEBoK to review or promote specific tool offerings. However, it is fair to state that current MBSE tools fall into three broad categories: 1) Functional decomposition tools that use IDEF0 (also called IPO) diagrams, N2 diagrams, functional flow block diagrams, etc., 2) Object-oriented tools that implement the Object Management Group's Systems Modeling Language (SysML), and 3) Mathematical modeling tools.

This migration for systems engineering might have begun in the late 90's. The INCOSE INSIGHT publication proclaimed that MBSE was a new paradigm (INSIGHT 1998). Cloutier (2004) addressed the migration from a waterfall systems engineering approach to an object-oriented approach on the Navy Open Architecture project. At that time, SysML did not exist, and the teams were using the Unified Modeling Language (UML) that was predominately a software modeling tool. Zdanis & Cloutier (2007a, 2007b) addressed the use of activity diagrams instead of sequence diagrams for systems engineering based on the newly released SysML. In 2009, the INCOSE INSIGHT publication proclaimed MBSE was THE new paradigm (INSIGHT 2009).

Approach

In 2009, a survey was commissioned by the Object Management Group (OMG) with the intent of informing the SysML Working Group on necessary changes to SysML since its first release (Cloutier & Bone 2010). That survey focused on process more than adoption. Beginning in 2012, INCOSE has commissioned three more surveys to understand adoption trends and obstacles. The survey instrument remained relatively unchanged for 2012, 2014, and 2018 (Cloutier 2015, Cloutier 2019a). In January of 2019, the Jet Propulsion Lab (JPL) conducted an MBSE Workshop (Cloutier 2019b). A survey of those participants was conducted, and the intent of the questions was to augment knowledge gained from the 2018 survey. The table below shows the number of respondents in each of the surveys.

Table 1. MBSE Survey Purposes and Responses (SEBoK Original)

Year	Survey Purpose	Responses
2012	INCOSE MBSE Initiative	134
2014	INCOSE MBSE Initiative	205
2018	INCOSE MBSE Initiative	661
2019	JPL MBSE Workshop	98

Responses and Response Demographics

Each survey was sent to a diverse group of MBSE practitioners. Table 2 shows that of the 661 responses for the 2018 survey, 410 indicated their country of origin. This international representation is similar to all surveys conducted.

Table 1. MBSE Survey Purposes and Responses (Cloutier 2019, used with permission)

Country	Responses	Country	Responses
USA	197	Israel	4
United Kingdom	52	Singapore	3
France	30	China	2
Germany	28	New Zealand	2
Australia	20	Poland	2
Netherlands	19	Russia	1
Japan	8	Romania	1
Canada	6	Turkey	1
Italy	6	Columbia	1
Sweden	6	Norway	1
South Africa	5	South Korea	1
Switzerland	4	UAE	1
Brazil	4	Belarus	1
India	4		

As part of the demographics, Figure 1 shows the represented industries. Because the “Other” category was so large, the data was analyzed to better understand Figure 2.

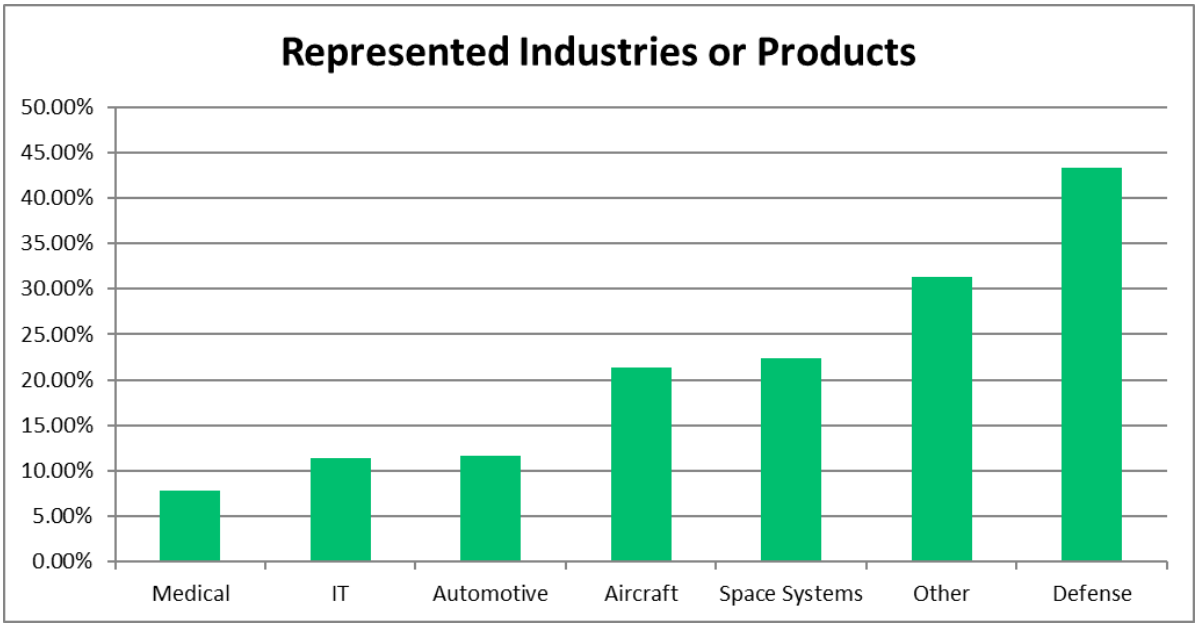

Figure 1. Industries Represented in the 2018 MBSE Survey. (Cloutier 2019a, used with permission)

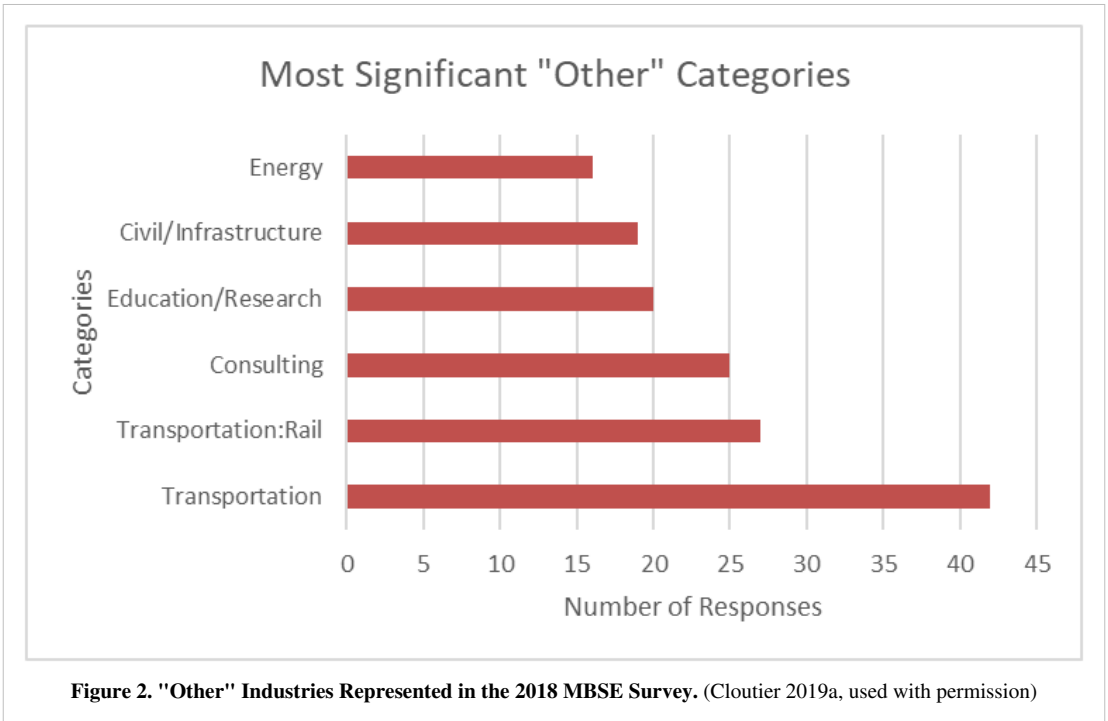

Figure 2. "Other" Industries Represented in the 2018 MBSE Survey. (Cloutier 2019a, used with permission)

The 2018 survey indicated that there seems to be an increased application of MBSE in traditionally civil engineering industries – specifically energy, infrastructure, and transportation (Figure 2) One of the most interesting aspects of the 2018 survey is the finding that MBSE is being applied in the early phases of systems engineering, and less so in the later phases as shown in Figure 3.

Figure 3. MBSE is More Likely to be Used in Early Stages of Systems Engineering. (Cloutier 2019a, used with permission)

This was confirmed by the JPL question "Where do we believe MBSE holds the most promise?" Figure 4 shows that 76% of the responses indicated system/subsystem architecting, 42% thought requirements analysis, and 39% believed early conceptualization (note: the question allowed for multiple answers).

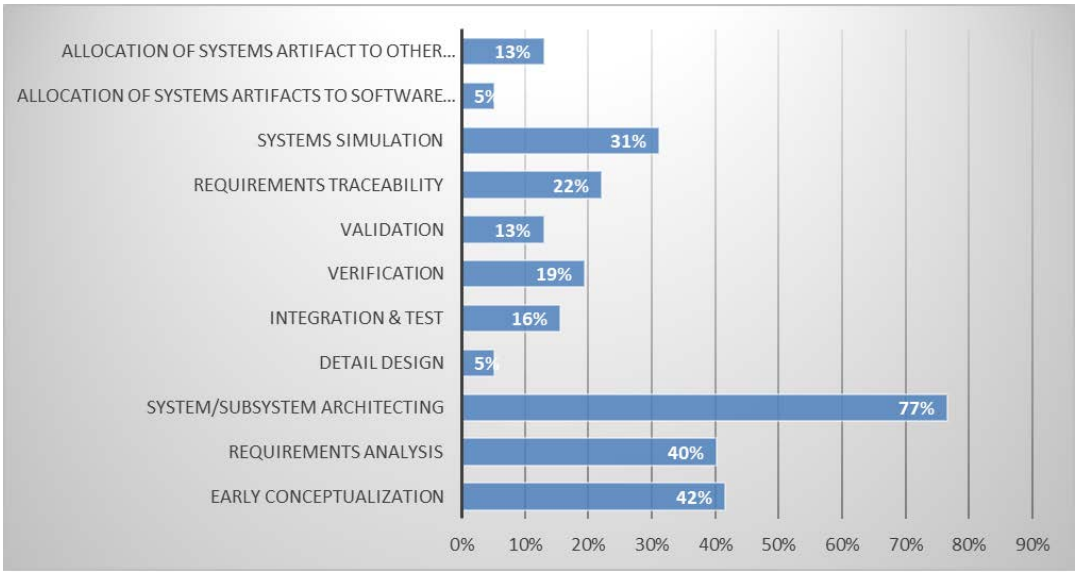

Figure 4. JPL Workshop Response Regarding "Where MBSE Holds the Most Promise." (Cloutier 2019b, used with permission)

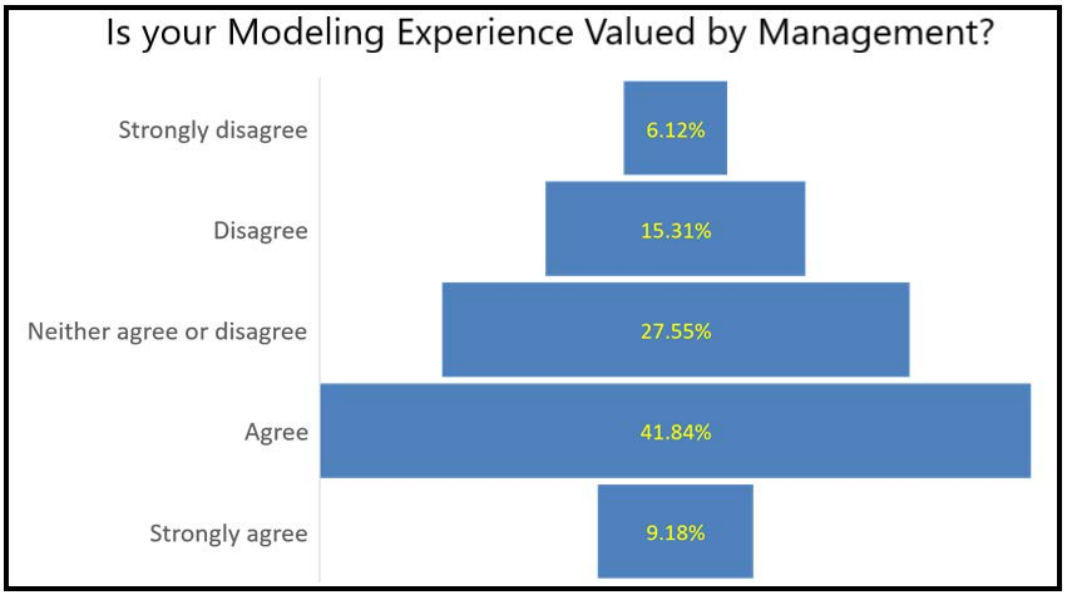

Figure 5. JPL Workshop Response Regarding "Is Your Modeling Experience Valued by Management?"(Cloutier 2019b, used with permission)

When asked whether the JPL survey respondents believed that their systems modeling experience is recognized as a valued skill supporting career growth of systems engineers in their organization, just over 50% believed management valued their experience. A smaller number, 21%, believed their modeling experience was not valued (Figure 5).

Key Adoption Trends

The remainder of this article will look at some of the trends identified across the surveys, from 2009 to 2018. Figure 6 shows that MBSE is moving from a defense and space dominated practice into other industries as discussed in Figure 4.

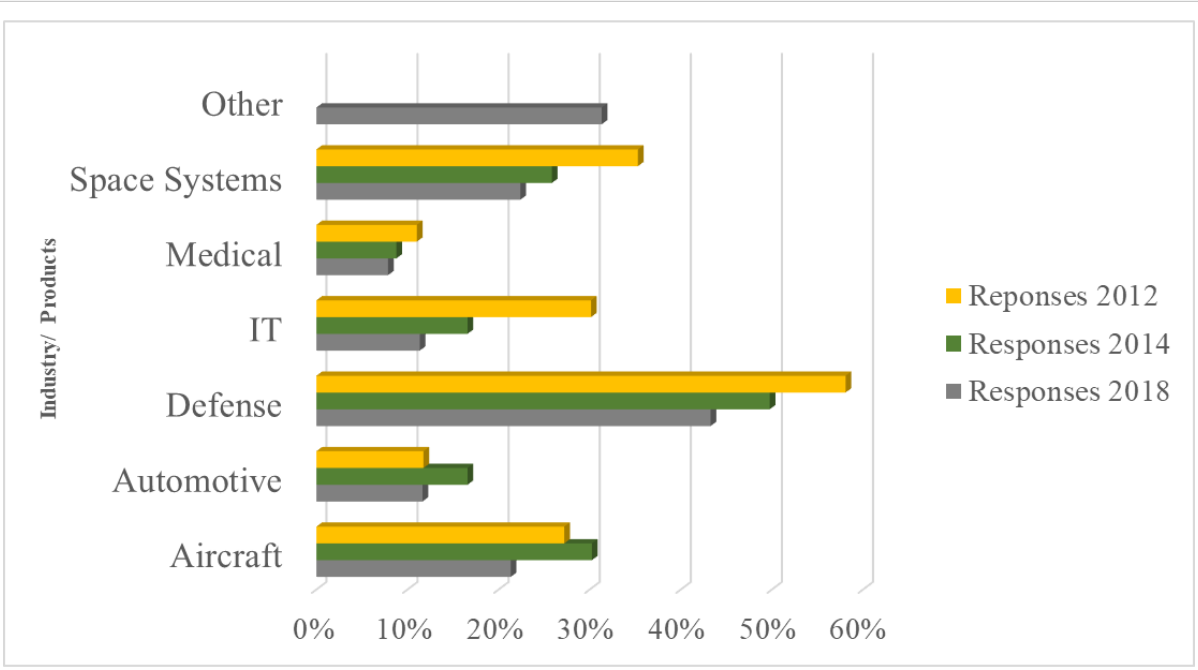

Figure 6. Shift of MBSE Adoption in New Industries. (Cloutier 2019a, used with permission)

Model-based systems engineering seems to be expanding in influence in that it is not just in the purview of systems engineers. While systems and software engineers find value in MBSE practices, Figure 6 demonstrates that the customer is finding value in MBSE practices. It is also interesting that software engineers' perceived value of MBSE is declining from survey to survey.

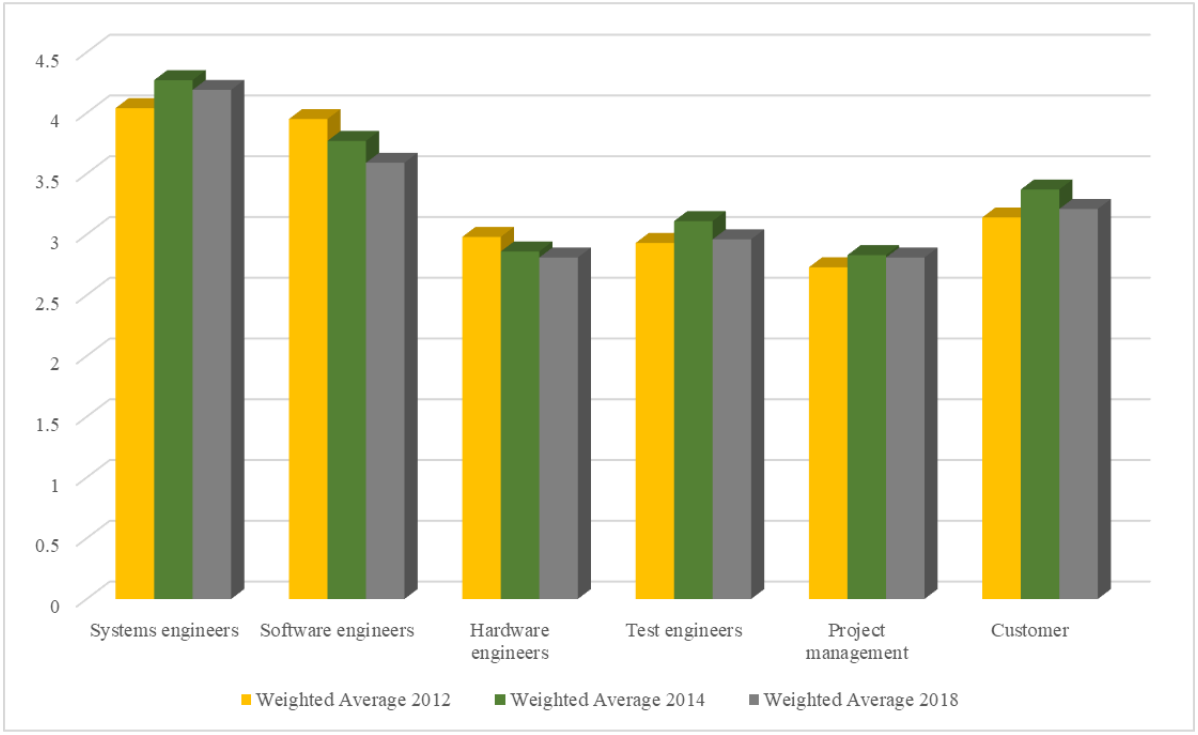

Figure 7. Perceived Value of MBSE Practices to Different Project Segments. (Cloutier 2019a, used with permission)

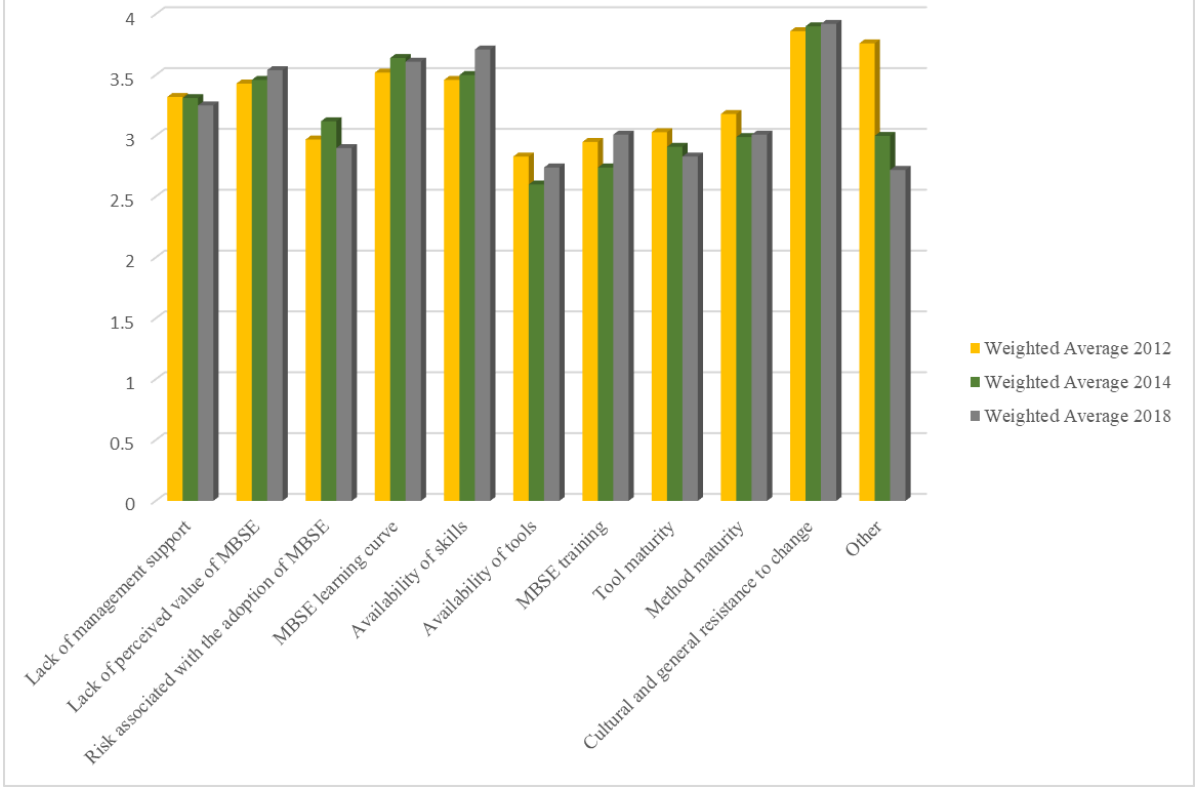

Figure 8. Inhibitors to the Successful Adoption of MBSE within an Organization/Company. (Cloutier 2019a, used with permission)

Figure 8 demonstrates that availability of MBSE skills and cultural and general resistance to change have continued to increase. Lack of perceived value reflects the findings in Figure 6 – software and hardware engineers are not seeing the value of MBSE.

Conclusions

Surveys conducted between 2012 and 2018 demonstrate that MBSE practices are spreading beyond traditional Defense and Space domains. Most MBSE practitioners are finding MBSE is most useful in the early project phases of conceptualization, requirements analysis, and systems architecting. There continues to be a skills shortage, yet companies/organizations are providing less training to improve MBSE skills. Both systems engineers, systems engineering management, and the systems engineering customer are finding value in using models to perform systems engineering.

Digital Engineering

- Lead Author:
- Ron Giachetti

-

The US Under Secretary of Defense for Research and Development released the US Department of Defense (DoD) Digital Engineering Strategy in June 2018 describing five goals to streamline the DoD acquisition process through the creation of a digital thread enabling the conception, design, and development of complex weapon systems (DoD 2018; Zimmerman 2017). The crux of digital engineering is the creation of computer readable models to represent all aspects of the system and to support all the activities for the design, development, manufacture, and operation of the system throughout its lifecycle. These computer models would have to be based on shared data schemata so that in effect a digital thread integrates all the diverse stakeholders involved in the acquisition of new weapon systems. The Digital Engineering Strategy anticipates digital engineering will lead to greater efficiency and improved quality of all the acquisition activities.

Relationship with MBSE

Model-based systems engineering (MBSE) is a subset of digital engineering. MBSE supports the systems engineering activities of requirements, architecture, design, verification, and validation. These models would have to be connected to the physics-based models used by other engineering disciplines such as mechanical and electrical engineering. One challenge remaining for digital engineering is the integration of MBSE with physics-based models.

Foundation to digital engineering is the representation of the system data in a format sharable between all stakeholders (Giachetti et al. 2015; Vaneman 2018). SysML 2.0 is one of several future developments promising to provide a representation sufficient to support digital engineering. An ontology defining the entities and relationships between them can be used to define the concepts relevant to systems engineering. Such a representation is necessary to create the digital thread linking all the models together in a cohesive and useful manner.

Digital Engineering as a Transformation

For many organizations, digital engineering represents a transformation of how they normally conduct systems engineering (e.g., see Bone et al. 2018) since most organizations conduct a document-intensive systems engineering process. The adoption of digital engineering requires concomitant changes to how organizations perform system engineering activities. Everything from documenting requirements, technical reviews, architecture design, and so forth would be based on the models in a digital engineering environment (Vaneman and Carlson, 2019). The digital thread would be the authoritative source of truth concerning the system data.

Digital Twin

A digital twin is a related yet distinct concept to digital engineering. The digital twin is a high-fidelity model of the system which can be used to emulate the actual system. An organization would be able to use a digital twin to analyze design changes prior to incorporating them into the actual system.

Set-Based Design

- Lead Authors:
- Eric Specking, Gregory S. Parnell, and Ed Pohl

-

Set-based design (SBD) is a complex design method that enables robust system design by 1) considering a large number of alternatives, 2) establishing feasibility before making decisions, and 3) using experts who design from their own perspectives and use the intersection between their individual sets to optimize a design (Singer, Doerry, and Buckley 2009). Model-based engineering (MBE)/model-based systems engineering (MBSE) with an integrated framework can enable the use of SBD tradespace exploration, for some situations (i.e. early-design stage with low fidelity models), in near-real time (Specking et al. 2018a). This article provides insights on using model-based design to create and assess alternatives with set-based design.

Introduction

SBD analyzes sets of alternatives instead of single solutions. Sets are "two or more design points that have at least one design option in common" (Specking et al. 2018b) or "the range of options for a design factor" (Singer et al. 2017). A design factor is a "solution parameter, characteristic, or relationship that influences the design at the system level" (Singer et al. 2017). Systems engineers should develop sets determining the design factors and separating the design factors into set drivers or set modifiers. Set drivers are "fundamental design decisions that define the system characteristics that enable current and future missions," while set modifiers are "design decisions that are 'added on' to the system and can be modified to adapt for new missions and scenarios" (Specking et al. 2018b).

SBD is not the best design method for every situation. SBD is particularly useful in early-stage design and if the project contains the following attributes:

- A large number of design variables,
- Tight coupling among design variables,
- Conflicting requirements,
- Flexibility in requirements allowing for trades, or
- Technologies and design problems not well understood – learning required for a solution (Singer et al. 2017)

In early-stage design, SBD helps inform requirements analysis and assess design decisions (Parnell et al. 2019). Quantitative SBD requires an integrated MBE environment to assess the effects of constraining and relaxing requirements on the feasible tradespace. For example, Figure 2 demonstrates the effects of constraining or relaxing requirements of an unmanned aerial vehicle case study with all of the explored designs in orange, the tradespace affected by non-requirement constraints (e.g. physics with requirements relaxed to not affect the tradespace) in blue, the original UAV feasible tradespace in yellow, and the relaxed (black)/constrained (red) tradespaces.

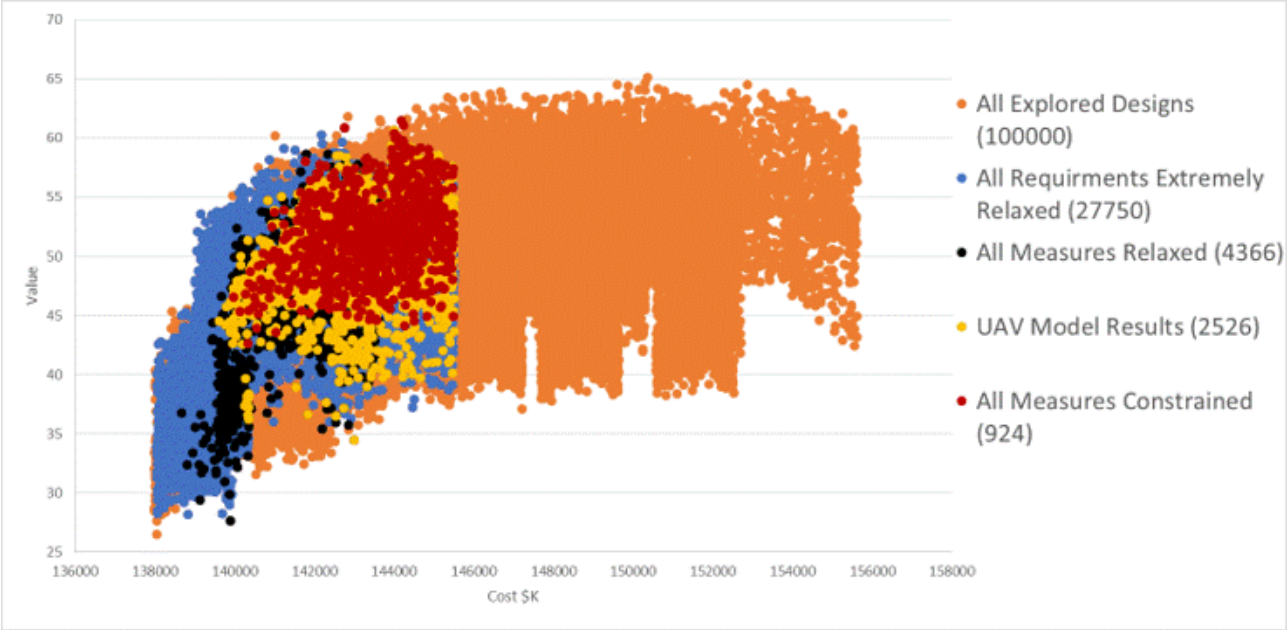

Figure 1. Effects of Requirements on the UAV's Feasible Tradespace (Parnell et al. 2019, used with permission)

The tornado diagram seen in Figure 3 shows results of a one requirement at a time analysis. This makes it easy to see how the constraining/relaxing of each individual requirement affects the feasible tradespace. Figure 3 shows that the requirements “Detect Human Activity at Night” and “Detect Human Activity in Daylight” have the greatest impact on the feasible tradespace.

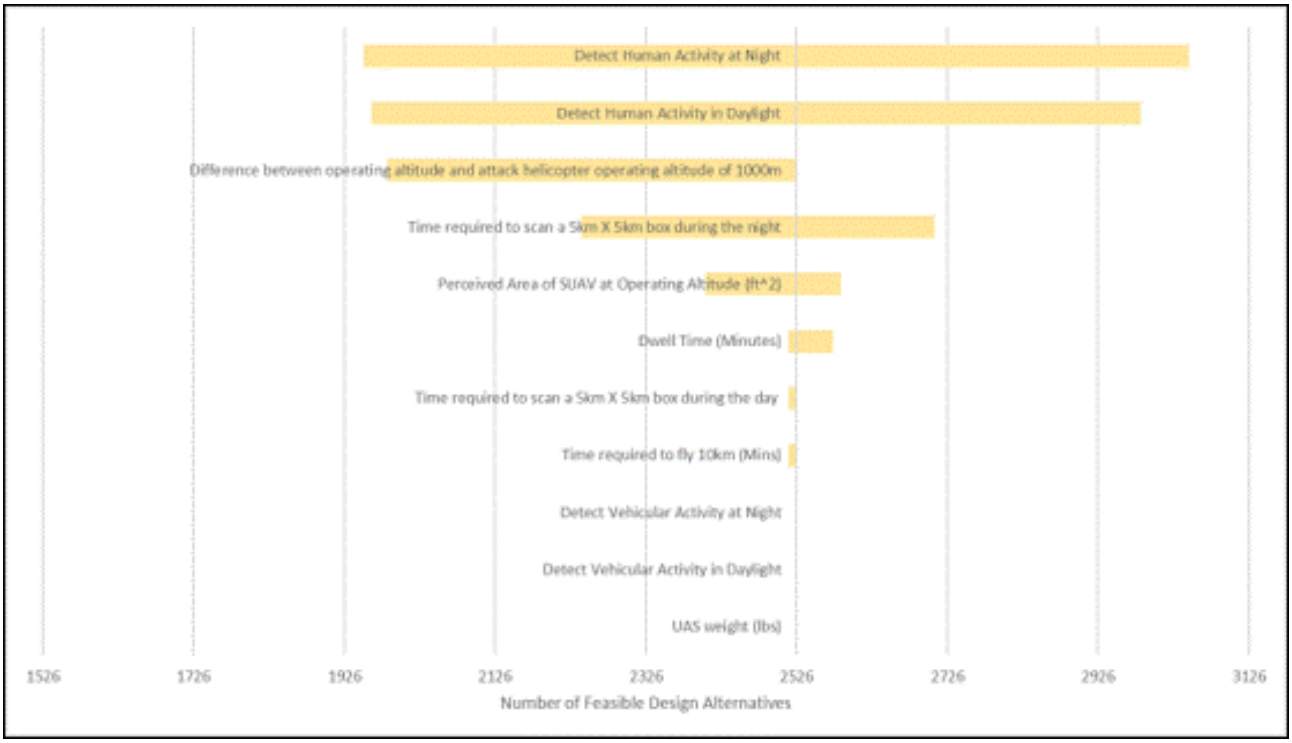

Figure 2. UAV Case Study Results of One-by-One Requirement Analysis (Parnell et al. 2019, used with permission)

Changing the requirements does not always translate to finding improved designs. The individual one requirement at a time analysis scatterplot provides important information, as seen in an example illustration in Figure 4. It is important to carefully analyze the Pareto Frontier created by each change (represented by a different color) and compare it to the Pareto Frontier of the original analysis. If the original requirement level produces better

alternatives, then it does not make sense to change (constrain or relax) the requirement.

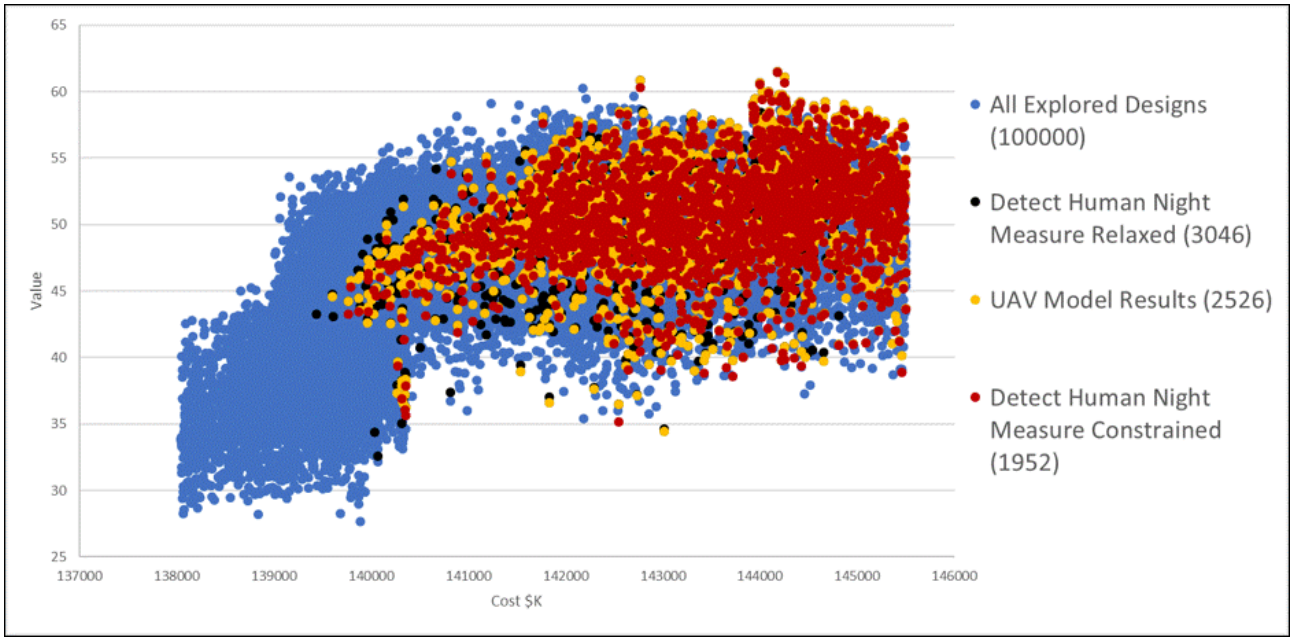

Figure 3. Effect on Feasible Tradespace by Changing Most Sensitive UAV Requirement (Specking et al. 2019, used with permission)

Additionally, using SBD can add value to the overall project and team. Some of the advantages include:

- enabling reliable, efficient communications,
- allowing much greater parallelism in the process, with much more effective use of subteams early in the process,
- allowing the most critical, early decisions to be based on data, and
- promoting institutional learning (Ward et al. 1995).

System Analyst Set-Based Design Tradespace Exploration Process

Figure 4 illustrates SBD as a concept for system design and analysis. This SBD illustration contains 5 distinct characteristics:

1. start by determining the business/mission needs and system requirements;
2. use the business/mission needs and system requirements to perform design and analysis techniques throughout time in the exploratory, concept, and development stages of the system's life cycle;
3. perform design and analysis concurrently as much as possible;
4. inform requirement analysis by using feasibility, performance, and cost data; and
5. consider a large number of alternatives through the use of sets and slowly converge to a single point solution (Specking et al. 2019).

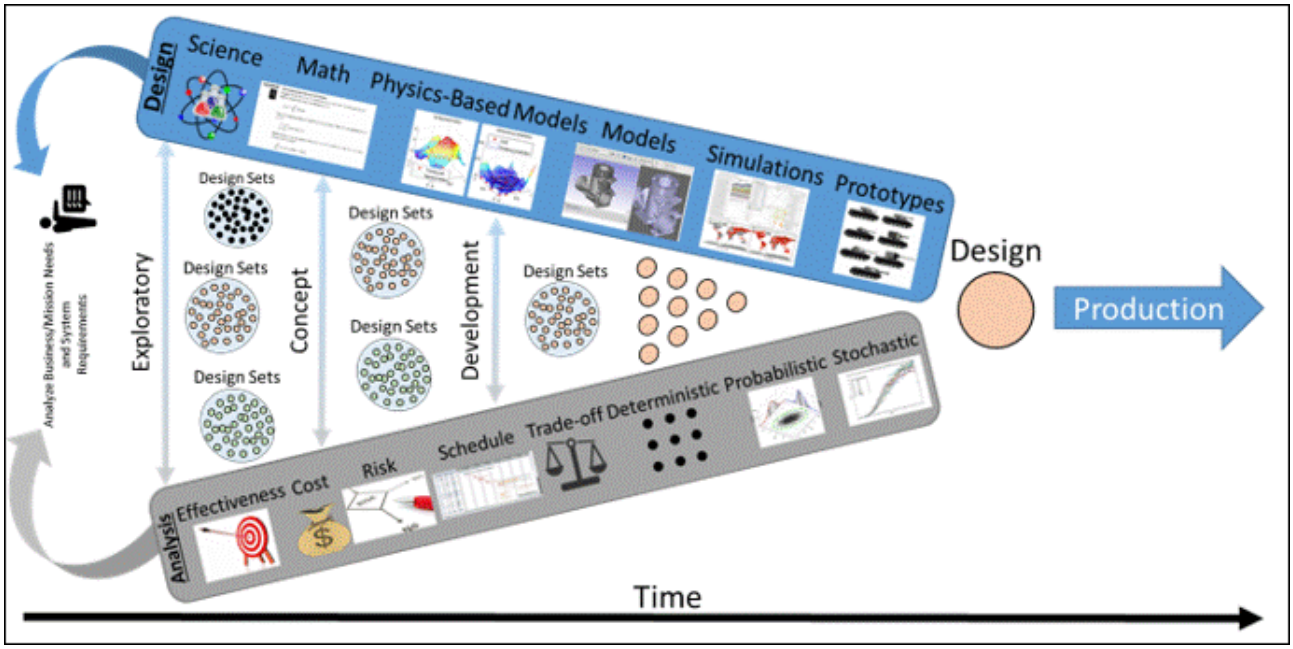

Figure 4. SBD Conceptual Framework for Systems Design (Specking et al. 2019, used with permission)

SBD is a social-technical process and should involve input and interactions from several teams, but Figure 6 provides a SBD tradespace exploration process for system analysts (Specking et al. 2019). This eight-step process is especially useful to perform early-stage design (Specking et al. 2018b). The system analyst starts by analyzing the business/mission needs and system requirements. Systems engineers use this information, along with models and simulations developed by themselves or provided by systems and subsystem teams, to develop an integrated model. Systems engineers include requirements to assess feasible and infeasible alternatives using this integrated model. They explore the tradespace by treating each design decision as a uniform (discrete or continuous) random variable. An alternative consists of an option from every design decision. Systems engineers then use the integrated model to evaluate each alternative and to create the feasible tradespace. Monte Carlo simulation is one method that enables a timely alternative creation and evaluation process. The created tradespace will consist of infeasible and feasible alternatives based upon the requirements and any physics-based performance models and simulations. Systems engineers should work with the appropriate stakeholders to inform requirements when the tradespace produces a significantly small number of or no feasible alternatives. In addition to feasibility, systems engineers should also analyze each design decision by using descriptive statistics and other analyses and data analytics techniques. This information provides insights into how each design factor influences the feasible tradespace. Once the tradespace contains an acceptable number of alternatives, it is then classified by sets. This is an essential part of SBD. If the set drivers or design factors are not known, systems engineers should view the tradespace by each design decision for insights. Systems engineers should use dominance analysis and other optimization methods to find optimal or near optimal alternatives based upon the measures of effectiveness. Systems engineers should explore the remaining sets for additional insights on the feasible tradespace and the requirements. The final part of this process is to select one or more sets to move to the next design-stage. It should be noted that this process contains cycles. At any part of this process, systems engineers should use the available information, such as from tradespace exploration or set evaluation, to inform requirement analysis or update the integrated model. Additionally, the systems engineer should update the integrated model with higher fidelity models and simulations as they become available. The key is to have the “right” information from the “right” people at the “right” time.

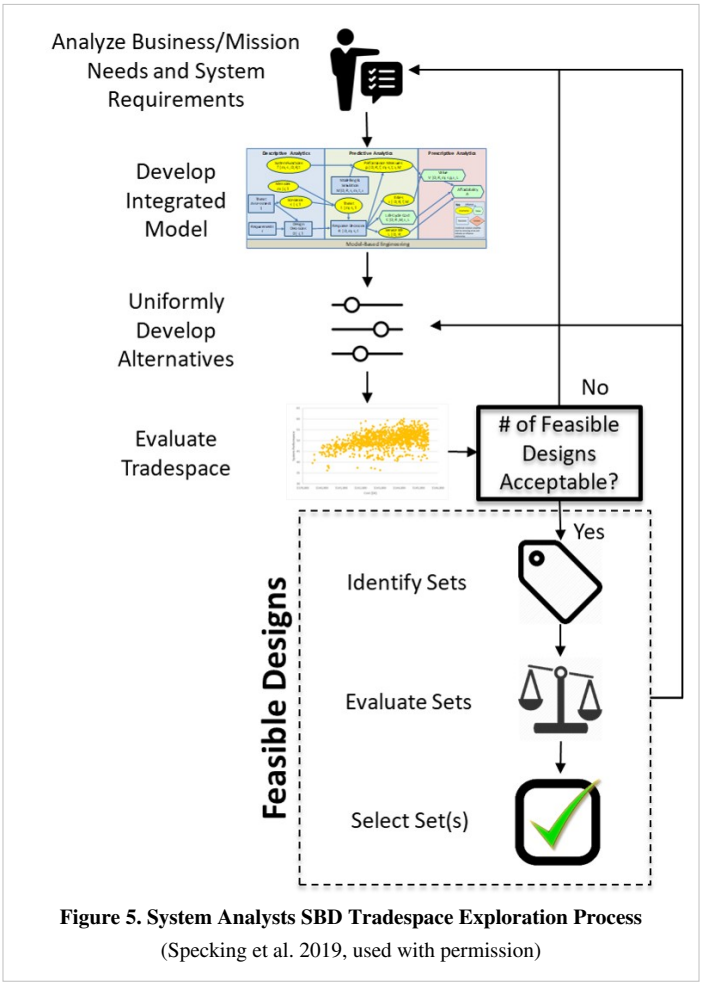

Figure 5. System Analysts SBD Tradespace Exploration Process
(Specking et al. 2019, used with permission)

Emerging Research

Emerging Research

- Lead Authors:
- Robert Cloutier and Arthur Pyster

-

The Emerging Research topic under the SEBoK Emerging Knowledge is a place to showcase some of the systems engineering research published in the past 3-5 years.

Doctoral Dissertations

Doctoral level systems engineering research has taken root over the last two decades. Additionally, many institutions have either an Industrial Engineering or Systems Engineering Master's program. This has enabled new and interesting research to be conducted. Here you will find bibliographic citations and summaries for recently defended research.

Towards Early Lifecycle Prediction of System Reliability

Salter, C. "Towards early lifecycle prediction of system reliability," Ph.D. dissertation University of South Alabama, Mobile, Alabama, July 2018. Available: ProQuest Store [1]

Reliability is traditionally defined as "the probability that an item will perform a required function without failure under stated conditions for a stated period of time" (O'Connor, 2012). This definition is applicable to all levels of a system, from the smallest part to the system as a whole. Predicting reliability requires extensive knowledge of the system of interest, thus making prediction difficult and complex. This problem is further complicated by the desire to predict system reliability early in the acquisition lifecycle. This work set out to develop a model for the prediction of system reliability early in the system lifecycle. The model utilizes eight factors: number of system requirements, number of major interfaces, number of operational environments, requirements understanding, technology maturity, manufacturability, company experience, and performance convergence. These factors come together to form a model much like the software engineering and systems engineering models COCOMO and COSYSMO. This work provides the United States Department of Defense a capability that previously did not exist: the estimation of system reliability early in the system lifecycle. The research demonstrates that information available during early system development may be used to predict system reliability. Through testing, the author found that a model of this type could provide reliability predictions for military ground vehicles within 25% of their actual recorded reliability values.

Toward the Evolution of Information Digital Ecosystems

Lippert, K. "Toward the evolution of information digital ecosystems," Ph.D dissertation, University of South Alabama, Mobile, Alabama, May 2018. Available: ProQuest Store [2].

Digital ecosystems are the next generation of Internet and network applications, promising a whole new world of distributed and open systems that can interact, self-organize, evolve, and adapt. These ecosystems transcend traditional collaborative environments, such as client-server, peer-to-peer, or hybrid models (e.g., web services) to become a self-organized, interactive environment. The complexity of these digital ecosystems will encourage evolution through adaptive processes and selective pressures of one member on another to satisfy interaction,

adaptive organization, and, incidentally, human curiosity. This work addresses one of the essential parts of the digital ecosystem – the information architecture. The research, inspired by systems thinking influenced by both biological models and science fiction, applies the TRIZ method to the contradictions raised by evolving data. This inspired the application of patterns and metaphor as a means for coping with the evolution of the ecosystem. The metaphor is explored as a model of representation of rapidly changing information through a demonstration of an adaptive digital ecosystem. The combination of this type of data representation with dynamic programming and adaptive interfaces will enable the development of the various components required by a true digital ecosystem.

Cybersecurity Decision Patterns as Adaptive Knowledge Encoding in Cybersecurity Operations

Willett, K. "Cybersecurity decision patterns as adaptive knowledge encoding in cybersecurity operations", Ph.D. dissertation, Stevens Institute of Technology, Hoboken, NJ, July 2016. Available: https://pqdtopen.proquest.com/doc/1875237837.html?FMT=ABS.

Cyberspace adversaries perform successful exploits using automated adaptable tools. Cyberspace defense is too slow because existing response solutions require humans in-the-loop across sensing, sense-making, decision-making, acting, command, and control of security operations (Dōne et al. 2016). Security automation is necessary to provide for cyber defense dynamic adaptability in response to an agile adversary with intelligence and intent who adapts quickly to exploit new vulnerabilities and new safeguards. The rules for machine-encoding security automation must come from people; from their knowledge validated through their real-world experience. Cybersecurity Decision Patterns as Adaptive Knowledge Encoding in Cybersecurity Operations introduces cybersecurity decision patterns (CDPs) as formal knowledge representation to capture, codify, and share knowledge to introduce and enhance security automation with the intent to improve cybersecurity operations efficiency for processing anomalies.

INCOSE & IEEE Periodicals and Events

Every year, the International Council on Systems Engineering (INCOSE) holds one International Workshop and one International Symposium, as well as regular meetings of various working groups, to encourage discussions of emerging needs and sharing of experience within Systems Engineering community. All papers and presentations from these events are available for free for INCOSE members, or with a fee for non-members via Wiley. The library can be access here: https://www.incose.org/products-and-publications/papers-presentations-library#

Additionally, INCOSE also publish periodicals, which include: Systems Engineering (SE Journal), INSIGHT (magazine), and INCOSE Members Newsletter. These periodicals are available as PDF, free for INCOSE members and with a fee for non-members, or as hard copies. More information can be found here: https://www.incose.org/products-and-publications/periodicals

The Institute of Electrical and Electronics Engineers (IEEE) Systems Council also holds multiple annual conferences, such as the International Systems Conference (SysCon), on systems engineering, resulting in a large pool of publications. These publications can be found via: https://ieeesystemscouncil.org/publications

NSF- and SERC-funded Research

The National Science Foundation (NSF), Division of Civil, Mechanical, and Manufacturing Innovation (CMMI) has been funding research in academia on systems engineering under Engineering Design and Systems Engineering (EDSE) program. According to NSF-EDSE website [3], the program "seeks proposals leading to improved understanding about how processes, organizational structure, social interactions, strategic decision making, and other factors impact success in the planning and execution of engineering design and systems engineering projects". Research under this program can be found via Award Search feature on NSF website: https://www.nsf.gov/awardsearch/advancedSearch.jsp (Enter "CMMI" for NSF Organization and "EDSE" for Program).

The Systems Engineering Research Center (SERC) is a University-Affiliated Research Center of the US Department of Defense, consisting of 22 collaborator universities in the US and funding research on different aspects of Systems Engineering, including Enterprises and System of Systems, Trusted Systems, Systems Engineering and Systems Management Transformation. More information can be found here: https://sercuarc.org/serc-programs-projects/esos/

Glossary

A

Absorption (glossary)

> *The ability of a system to withstand a disturbance without a fundamental breakdown in the system's performance or structure* -- adapted from (Woods 2006)

Absorption is a resilience principle that supports the robustness attribute according to Jackson and Ferris (2013).

Sources

Woods, David D. 2006. "Essential Characteristics of Resilience." In E. Hollnagel, D. D. Woods, and N. Leveson. *"Resilience Engineering: Concepts and Precepts."* Aldershot, UK: Ashgate Publishing Limited.

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Discussion

This definition is in the context of resilience for which David Woods is an authority.

Abstract Model (glossary)

> *(1) A simplified description, especially a mathematical one, of a system or process, to assist calculations and predictions.* (Pearsall 2012)
>
> *(2) An abstract or conceptual representation of a system that does not have a physical or concrete existence.* (Created for SEBoK)

Sources

(1) Pearsall, Judy (editor). 2012. Oxford Dictionaries Online. Oxford, England, UK: Oxford University Press. Available at : http://oxforddictionaries.com/definition/english/model [1].

(2) This definition was developed for the SEBoK v. 1.0.

Discussion

An abstract model contrasts with a concrete physical model. It can be further classified as descriptive or analytical (See article Types of Models).

References

[1] http://oxforddictionaries.com/definition/english/model

Abstract Syntax (glossary)

(1) *A form of representation of data that is independent of machine-oriented structures and encodings and also of the physical representation of the data.* (Dictionary.com 2012)

(2) *The set of constructs and associated rules to create well-formed models.* (Created for SEBoK)

Sources

Discussion

None.

Abstraction (glossary)

(1) *A view of an object that focuses on the information relevant to a particular purpose and ignores the remainder of the information.* (ISO/IEC 2010)

(2) *The process of formulating a view.* (ISO/IEC 2010)

(3) "A [simplified] replica of the concrete. For example, the abstract architectural principle of redundancy can be realized in the concrete manifestation of a concrete communications system." (Lonergan, 1992)

Source

(3) Lonergan, Bernard, "Insight" University of Toronto Press, Toronto, 1992, p. 111.

Discussion

None.

Acceptance Criteria (glossary)

The procurement specification, in the context of the overall agreement, should clearly state the criteria by which the acquirer will accept delivery from the supplier. A verification matrix can be used to clarify these criteria. (INCOSE 2011, Section 6.1.15, p 259)

Source

INCOSE. 2011. *Systems Engineering Handbook: A Guide for System Life Cycle Processes and Activities*. Version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2

Discussion

None.

Acceptance Sampling (glossary)

In acceptance sampling many examples of a product are presented for delivery. The consumer samples from the lot and each member of the sample is then either categorized as "acceptable" or "unacceptable" based on an attribute (attribute sampling) or measured against one or more metrics (variable sampling). Based on the measurements, an inference is made as to whether the lot meets the customer requirements. There are four possible outcomes of the sampling of a lot, as shown in Table 1.

Table 1. Truth Table - Outcomes of Acceptance Sampling. (SEBoK Original)

	Lot meets requirement	**Lot fails requirement**
Sample passes test	No error	Consumer risk
Sample fails test	Producer risk	No error

A sample acceptance plan balances the risk of error between the producer and consumer. Detailed ANSI/ISO/ASQ standards describe how this allocation is performed. (ANSI/ISO/ASQ 1993)

Sources

ANSI/ISO/ASQ. 1993. *Statistics—Vocabulary and Symbols—Statistical Quality Control.* Philadelphia, PA, USA: American National Standards Institute (ANSI)/International Standards Organization (ISO)/American Society for Quality(ASQ) :A3534-2-1993.

Discussion

A company cannot test every one of its products due to either the need for destructive testing requirements, or the volume of products being too large. Acceptance sampling solves this by testing a sample of product for defects. The process involves batch size, sample size and the number of defects acceptable in the batch. This process allows a company to measure the quality of a batch with a specified degree of statistical certainty without having to test every unit of product. The statistical reliability of a sample is generally measured by a t-statistic.

Acquirer (glossary)

The stakeholder that acquires or procures a product or a service from a supplier. (ISO/IEC 2010)

Source

ISO/IEC. 2010. *Systems and Software Engineering -- Life Cycle Management -- Part 2: Guide for the Application of ISO/IEC 15288 (systems life cycle processes).* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC DTR 24748-2.

Discussion

None.

Acquisition (glossary)

The process of obtaining a system, product or service. (ISO/IEC/IEEE 2015)

Sources

ISO/IEC/IEEE. 2015. *Systems and Software Engineering -- System Life Cycle Processes*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions / Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 15288:2015.

Discussion

None.

Acquisition Strategy (glossary)

A comprehensive, integrated plan that identifies the acquisition approach and describes the business, technical, and support strategies that management will follow to manage program risks and meet program objectives. The acquisition strategy should define the relationship between the acquisition phases and work efforts, and key program events such as decision points, reviews, contract awards, test activities, production lot/delivery quantities, and operational deployment objectives. (DAU 2010)

Source

DAU. 2010. *Defense Acquisition Guidebook (DAG)*. Ft. Belvoir, VA, USA: Defense Acquisition University (DAU)/U.S. Department of Defense (DoD).

Discussion

None.

Activity (glossary)

> *According to ISO/IEC/IEEE 24774, activities are defined as "set of cohesive tasks of a process".* (ISO/IEC/IEEE 2021)

Sources

ISO/IEC/IEEE. 2021. *Systems and software engineering — Life cycle management — Specification for process description*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24774:2021, Clause 3.1.

Discussion

None.

Adaptability (glossary)

(1) *An adaptive system is one that is able to change itself or its environment if its effectiveness is insufficient to achieve its current or future goals or objectives.* (Ackoff 1971)

(2) *Attributes of software that bear on the opportunity for its adaptation to different specified environments without applying other actions or means than those provided for this purpose for the software considered.* (INCOSE 1998)

(3) *The ability of a system to acclimate physically and functionally to a new operating environment with a minimal degree of degradation to capability performance.* (Wasson 2006)

(4) *the ability of the system to become suitable for a new use or purpose and to what range or sources of variation.* According to Jackson (2016) adaptability is an attribute of a resilient system.

Sources

(1) Ackoff, R.L. 1971. "Towards a System of Systems Concepts." *Management Science* 11: 11.

(2) INCOSE. 1998. INCOSE SE Terms Glossary. In: I*NCOSE Concepts and Terms,* Working Group (ed.). Seattle, WA, USA: International Council on Systems Engineering.

(4) Jackson, Scott. 2016. "Evaluation of resilience principles for engineered systems." PhD Research, Engineering, University of South Australia.

Discussion

(1) A system science definition, which applies to any level of system

(2) The term in a software context where it is frequently used, the same idea could apply to human systems. The 1998 INCOSE SE Terms Glossary is an authoritative source.

(3) A more general definition, which applies to complex engineered systems. The book by Wasson is a standard systems engineering textbook.

Address (glossary)

> *Insert definition here.* (Reference YEAR)

Source

Insert full source info (Author Last, FI. YEAR. TITLE. Publisher. URL)

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Adversity (glossary)

> *A condition that may degrade the desired capability of a system.* (Brtis 2016)

Source

Brtis, John. 2016. How to Think About Resilience in a DoD Context. Colorado Springs, CO: MITRE Corporation.

Discussion

In the context of resilience adversity can include an encounter with a threat or an internal disruption such as human error.

Aggregate (glossary)

> *A subset of a system made up of several system elements and physical interfaces (indiscriminately system elements or sub-systems) on which a set of verification and validation actions is applied.* (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

None.

Agile (glossary)

(1) Response ability state marked by high competence at both proactive and reactive change. (Dove 2001, 69)

(2) Project execution methods can be described on a continuum from "adaptive" to "predictive." Agile methods exist on the "adaptive" side of this continuum, which is not the same as saying that agile methods are "unplanned" or "undisciplined." (INCOSE 2011, 40, 183)

Source

Discussion

None.

Agility (glossary)

Derivation of the physical ability to act (response ability) and the intellectual ability to find appropriate things to act on (knowledge management). (Dove 2001, p. 9)

Source

Dove, R. 2001. *Response Ability: The Language, Structure, and Culture of the Agile Organization*. New York, NY, USA: John Wiley & Sons.

Discussion

None.

Agreement (glossary)

> *Mutual acknowledgment of terms and conditions under which a working relationship is conducted.* (ISO/IEEE 2008, 1, Section 4.4)

Source

ISO/IEEE. 2008. *Systems and Software Engineering — Software Life Cycle Processes*. Geneva, Switzerland: International Organization for Standards (ISO)/Institute of Electrical & Electronics Engineers (IEEE) Computer Society, ISO/IEEE 12207:2008(E).

Discussion

None.

Analytical Model (glossary)

> *Mathematical model into which data are loaded for analysis.* (Turban, et al 2010)

Source

Turban, E., R. Sharda, and D. Delen. 2010. *Decision Support and Business Intelligence Systems*, 9th ed. Prentice-Hall.

Discussion

In the context of systems engineering (SE), it may be considered that the model represents a System-of-Interest (SoI).

Antipattern (glossary)

> *(1) An antipattern is just like a pattern except that instead of a solution it gives something that looks superficially like a solution but isn't one.* (Koenig 1995)
>
> *(2) Pattern of failure.* (SEI 2012)

Sources

(1) Koenig, A. (March/April 1995). "Patterns and Antipatterns". Journal of Object-Oriented Programming 8, (1): 46–48.

(2) SEI 2012. *Patterns of Failure: System Archetypes.* Available at http://www.sei.cmu.edu/acquisition/research/pofsa.cfm.

Discussion

A full discussion of Antipatterns and how they relate to systems thinking can be found in Patterns of Systems Thinking

Architecting (glossary)

> (1) *Process of conceiving, defining, expressing, documenting, communicating, certifying proper implementation of, maintaining and improving an architecture throughout a system's life cycle* (ISO/IEC/IEEE 2011)
>
> (2) *The architecting process sometime involves the use of heuristics to establish the form of architectural options before quantitative analyses can be applied. Heuristics are design principles learned from experience.* (Rechtin 1990)

Source

(1) ISO/IEC/IEEE. 2011. Systems and software engineering - Architecture description. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE), ISO/IEC/IEEE 42010.

(2) Rechtin, E. 1990. *Systems Architecting: Creating & Building Complex Systems.* Upper Saddle River, NJ, USA: Prentice-Hall.

Discussion

None.

Architecture (glossary)

(1) *fundamental concepts or properties of a system in its environment embodied in its elements, relationships, and in the principles of its design and evolution* (ISO/IEC/IEEE 2015, Section 4.5)

(2) *The organizational structure of a system or component; the organizational structure of a system and its implementation guidelines.* (ISO/IEC 2009, 1)

(3) *Fundamental concepts or properties of a system in its environment embodied in its elements, relationships, and in the principles of its design and evolution.* (ISO/IEC 2011, section 3.2)

(2) ISO/IEC/IEEE. 2009. *Systems and Software Engineering — System and Software Engineering Vocabulary* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronic Engineers (IEEE) 2009 ISO/IEC/IEEE 24765:2009 [database online]. Available from http://pascal.computer.org/sev_display/index.action.

(3) ISO/IEC/IEEE. 2011. *Systems and Software Engineering — Architectural Description*. Geneva, Switzerland: International Organization for Standards (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 42010:2011.

Discussion

A few definitions are presented here to illustrate the different ways that authors define architecture. Note that many authors write extensively on architecture without ever defining what they mean by the term.

The use of the word *fundamental* (definitions (1) and (3)) is problematic, since it has no universal definition. In practice, the level of detail in an architecture depends on the context of use and the purpose to which it is being designed. In the early (conceptual) stages it might only contain a high-level description of the system as a whole, but in later stages the key features of all key subsystems need to be mapped out. An architectural description should therefore also justify what is included and what is excluded.

ISO/IEC/IEEE 15288:2015 is normative - see above. The architecture associated with a system-of-interest is conceptual and is realized through an architectural description.

ISO/IEC/IEEE 42010:2011 is normative - see above.

OMG 2010 is normative - “The organizational structure and associated behavior of a system. An architecture can be recursively decomposed into parts that interact through interfaces, relationships that connect parts, and constraints for assembling parts.”

Assembly Procedure (glossary)

A set of elementary assembly actions to build an aggregate of implemented system elements. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

This definition is most relevant to the usage of this term in the SEBoK (see System Integration article).

Assembly Tool (glossary)

An assembly tool is a physical tool used to connect, assemble or link several implemented system elements and to build aggregates (specific tool, harness, etc.). (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

This definition is most relevant to the usage of this term in the SEBoK (see System Integration article).

Assessment Criterion (glossary)

> *A characteristic used to assess or compare system elements, physical interfaces, physical architectures, logical architectures, or any such engineering element.* (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

This definition is most relevant to the usage of this term in the SEBoK in the context of System Analysis. Also see the Analysis and Selection between Alternative Solutions article.

Assessment Score (glossary)

> *A score that is obtained from assessing a component, a link, a physical architecture, or a functional architecture using a set of assessment criteria.* (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

This definition is most relevant to the usage of this term in the SEBoK in the context of System Analysis. Also see the Analysis and Selection between Alternative Solutions article.

Attribute (glossary)

> *An inherent property or characteristic of an entity that can be distinguished quantitatively or qualitatively by human or automated means.* (ISO/IEC/IEEE 2007)

Sources

ISO/IEC/IEEE. 2007. *Systems and software engineering - Measurement process*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC/IEEE 15939:2007.

Discussion

There are 8 definitions of attribute in the standards covered by the IEEE *Systems and Software Vocabulary Project* (sevocab). The included definition is the second, but best seems to capture the intended use of the term in SEBoK. Many uses of the term *attribute* are specific to database theory and formal modeling. See www.computer.org/sevocab for more detail.

SEVOCAB [1] contains the following note:

> *[An] attribute can refer either to general characteristics such as reliability, maintainability, and usability or to specific features of a software product. ISO 9000 distinguishes two types of attributes: a permanent characteristic existing inherently in something; and an assigned characteristic of a product, process or system (e.g. the price of a product, the owner of a product). The assigned characteristic is not an inherent quality characteristic of that product, process or system. An attribute expresses some characteristic that is generally common to the instances of a class. The name of the attribute is the name of the role that the value class plays in describing the class, which may simply be the name of the value class (as long as using the value class name does not cause ambiguity).*

References

Availability (glossary)

Availability is the probability that a repairable system or system element is operational at a given point in time, under a given set of environmental conditions.

Source

Adapted from the following sources:

ASQ. 2011. "Glossary: Availability." American Society for Quality. Available at http://asq.org/glossary/a.html.

DoD. 2010. "Acquipedia: Material Availability." Department of Defense. Available at https:/ / acc. dau. mil/ CommunityBrowser.aspx?id=387703.

ReliaSoft Corporation. 2003. "Availability and the Different Ways to Calculate it." Available at http:/ / www. weibull.com/hotwire/issue79/relbasics79.htm.

Discussion

The definition here is similar to the one given in (ASQ 2011) and in the Department of Defense. Availability has some additional definitions, characterizing what downtime is counted against a system. For **inherent availability**, only downtime associated with corrective maintenance counts against the system. For **achieved availability**, downtime associated with both corrective and preventive maintenance counts against a system. Finally, **operational availability** counts all sources of downtime, including logistical and administrative, against a system.

Availability can also be calculated instantaneously, averaged over an interval, or reported as an asymptotic value. **Asymptotic availability** can be calculated easily from the mean time to failure and the mean time to repair, but care must be taken to analyze whether or not a systems settles down or settles up to the asymptotic value, and how long it takes until the system approaches that asymptotic value.

B

Baseline (glossary)

> *A specification or product that has been formally reviewed and agreed upon, that thereafter serves as the basis for further development, and that can be changed only through formal change control procedures.* (ISO/IEEE 2008)

Sources

ISO/IEEE. 2008. *Systems and Software Engineering — Software Life Cycle Processes*. Geneva, Switzerland: International Organization for Standards (ISO)/Institute of Electrical & Electronics Engineers (IEEE) Computer Society, ISO/IEEE 12207:2008(E).

Discussion

There are 7 definitions of baseline in the standards covered by the IEEE sevocab database. The included definition seems most appropriate for SEBoK use. See http://www.computer.org/sevocab for more detail.

The SEVOCAB [1] entry provides 7 definitions followed by this note: *A baseline should be changed only through formal configuration management procedures. Some baselines may be project deliverables while others provide the basis for further work. Baselines, plus approved changes from those baselines, constitute the current configuration identification.*

[1] http://pascal.computer.org/sev_display/index.action

Behavior (glossary)

(1) Systems behavior is a change which leads to events in itself or other systems. Thus, action, reaction or response may constitute behavior in some cases. (Ackoff 1971)

(2) The effect produced when an instance of a complex system or organism is used in its operational environment. (Created for SEBoK)

Source

(1) Ackoff, R.L. 1971. "Towards a System of Systems Concepts". *Management Science 17*: 11. Hanover, MD, USA: INFORMS.

(2) This definition was developed for the SEBoK.

Discussion

(1) This is the system science definition. Any system has behavior if its actions are in some way visible to systems around it.

(2) This definition associates behavior with an emergent outcome of (complex) deployed system, more analogus to human/animal behavior. Taking this view, the whole organism has behavior but not any of its element systems; e.g., cars have behavior (when driven by people), engines have functions.

Behavioral Architecture (glossary)

(1) *An arrangement of functions and their sub-functions and interfaces (internal and external) which defines the execution sequencing, conditions for control or data-flow and the performance requirements to satisfy the requirements baseline.* (ISO/IEC 2010)

(2) *A set of inter-related scenarios.* (Created for SEBoK)

Sources

(1) ISO/IEC. 2010. Systems and Software Engineering, Part 1: Guide for Life Cycle Management. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 24748-1:2010.

(2) This definition was developed for the SEBoK.

Discussion

Within the terms and definitions related to System Architecture, the present SEBoK tries to fit the real practices and to provide some consistency between those terms.

Definition (1) comes from ISO/IEC/IEEE 24748 - 4 (past IEEE 1220, ISO/IEC 26702) as functional architecture; but modified because in the standard functional and behavioral aspects are mixed. In reality the functional architecture emphasizes more on transformations performed rather than the sequencing of their executions. See definition of functional architecture (glossary).

Definition (2) is a good suggestion to represent a behavioral architecture, because a scenario of functions chains the execution of functions taking into account synchronization between functions and arrival of triggers.

Binding (glossary)

(1) The point in time when relationships are established. (Created for SEBoK)

*(2) Static binding is done **once** and then the relationship remains unchanged.* (Created for SEBoK)

(3) Dynamic binding is established at the point of a request and disappears after the request has been satisfied. (Created for SEBoK)

Source

These definitions were developed for SEBoK v. 1.0.

Discussion

This definition is most relevant to the usage of this term in the SEBoK (See article Applications of Systems Engineering).

Black-Box System (glossary)

A device, system or object which can be viewed solely in terms of its input, output and transfer characteristics without any knowledge of its internal workings, that is, its implementation is "opaque" (black). (Ashby 1956)

Sources

Ashby, W R. 1956. *Introduction to Cybernetics*. "Chapter 11" London, UK: John Wiley & Sons.

Discussion

None.

Body of Knowledge (glossary)

(1) The purpose of the Guide to the Software Engineering Body of Knowledge is to provide a consensually validated characterization of the bounds of the software engineering discipline and to provide a topical access to the Body of Knowledge supporting that discipline. (Abran and Moore 2004)

> *(2) Identifies that subset of the project management body of knowledge generally recognized as good practice. "Generally recognized" means the knowledge and practices described are applicable to most projects most of the time, and there is consensus about their value and usefulness. "Good practice" means there is general agreement that the application of these skills, tools, and techniques can enhance the chances of success over a wide range of projects...The* PMBOK® Guide *also provides and promotes a common vocabulary within the project management profession…The Project Management Institute views this standard as a foundational project management reference for its professional development programs and certifications.* (PMI 2013)
>
> *(3) Document explicitly intended to capture the knowledge for entry into the practice of [an] engineering [discipline] at the professional level.* (ASCE 2008)

Source

(1) Abran, A. and J.W. Moore (exec. eds); P. Bourque and R. Dupuis (eds.). 2004. Guide to the Software Engineering Body of Knowledge (SWEBOK Guide). Piscataway, NJ, USA: The Institute of Electrical and Electronic Engineers, Inc. (IEEE). Available at: http://www.computer.org/portal/web/swebok.

Discussion

None.

Boundary (glossary)

Please see system boundary.

Business (glossary)

A business is an organization engaged in the trade of goods, services, or both to consumers. (Sullivan and Sheffrin 2003)

Source

Sullivan, A. and S.M. Sheffrin. 2003. *Economics: Principles in Action*. Upper Saddle River, NJ, USA: Pearson Prentice Hall.

Discussion

A business may be a commercial company, a not-for-profit organization, or state-owned. Its consumers may be individuals, projects, other businesses, or enterprises.

There are many different legal forms of businesses, which vary across political entities. In the context of the SEBoK, the term **business** would include a government agency.

The word **enterprise** is sometimes used synonymously with "business". However in the SEBoK, a **business** is a specific type of enterprise, usually a legal entity with a form of centralized management. An enterprise is a purposeful activity often involving collaboration across organizational boundaries.

Business Process (glossary)

> *An inter-related set of cross-functional activities or events that result in the delivery of a specific product or service to a customer.* (ISACA 2012)

Source(s)

ISACA. 2012. "Glossary of Terms: Business Process." Information Systems Audit and Control Association. Accessed July 23, 2012. Available at: http://www.isaca.org/Knowledge-Center/Documents/Glossary/glossary.pdf.

Discussion

None.

Business Process Outsourcing (glossary)

> *The transfer of internal business processes, such as customer relationship management, finance & accounting, human resources and procurement, to an external service provider.* (Gewald and Rouse 2012)

Source(s)

Gewald, H. and A. Rouse. 2012. "Comparing Business Process and IT Outsourcing Risks--An Exploratory Study in Germany and Australasia," 45th Hawaii International Conference on System Science (HICSS), 4-7 Jan. 2012, 275-284. Available at: http:/ / ieeexplore. ieee. org/ stamp/ stamp. jsp?tp=& arnumber=6148641& isnumber=6148595.

Discussion

The term business process outsourcing is often confounded with "information technology (IT) outsourcing", they are related but not synonymous. IT oriented companies and consultancies often do so. Gartner's definition is a good example: "the delegation of one or more IT-intensive business processes to an external provider that, in turn, owns, administrates and manages the selected processes based on defined and measurable performance metrics."[1]. Any business process may be outsourced.

Discussion

None.

Capability (glossary)

(1) *The ability to achieve a desired effect under specified (performance) standards and conditions through combinations of ways and means (activities and resources) to perform a set of activities.* (DoD 2009)

(2) *The ability to execute a specified course of action. It is defined by a user and expressed in non-equipment based operational terms.* (MOD 2004)

(3) *The ability to execute a specified course of action. A capability may or may not be accompanied by an intention.* (DoD 2009)

(4) *An outcome or effect which can be achieved through use of features of a system of interest and which contributes to a desired benefit or goal* (Created for SEBoK)

Source

(1) DoD. 2009. *DoD Architecture Framework (DoDAF)*, version 2.0. Washington, DC, USA: U.S. Department of Defense (DoD).

(2) MOD. 2004. *Ministry of Defence Architecture Framework (MODAF),* version 2. London, UK: U.K. Ministry of Defence.

(3) DoD. 2009. *Department of Defense Dictionary of Military and Associated Terms.* Washington, DC, USA: U.S. Department of Defense (DoD), Joint Publication 1-02, 17 March 2009.

(4) This definition was developed for the SEBoK.

Discussion

Capability provides an umbrella term for the ability to achieve many objectives and effects that may be specified during the SE lifecycle: missions, mission objectives, user needs, user requirements, system

In the defense context capability refers to an operational outcome available to the end user when engineered systems are deployed and fully supported (including trained people, logistics, doctrine, infrastructure, etc.) in an operational environment. It is used either to specify a required capability need (i.e., what is sought) or to describe the currently fielded capability (i.e., the currently available effect) to help identify gaps. The term capability has been defined to encourage military user to describe current and future needs independent of current solution technology

The term capability is less common outside of defense but is sometimes used to describe outcomes a user needs to achieve which connect the systems feature to the business or enterprise benefit. You can say that they lead your customer into understanding how the features you have deliver the benefit.

For example, a fingerprint scanner on a desktop computer can store passwords. This saves five minutes every time the user forgets a password and has to look it up or reset it, it also makes the computer more secure. The fingerprint scanner is the Feature, storing passwords is the Capability and saving time and increasing security the Benefit. This is likely to become a more common terminology as Systems Engineering looks to relate stakeholder needs more explicitly with business benefits, see Stakeholder Needs Definition

Capability Management (glossary)

(1) *Development and maintenance of all aspects of the ability to conduct certain types of missions in a given environment.* (Created for SEBoK)

(2) *The planning, organization, assessment and control of capabilities.* (Created for SEBoK)

Source

(1)-(2) These definitions were developed for SEBoK v. 1.0.

Discussion

None.

Capacity (glossary)

> *An attribute of resilience that includes all capabilities to enable a system to withstand a disruption* – adapted from (Jackson 2010)

Sources

Jackson, S. 2010. *Architecting Resilient Systems: Accident Avoidance and Survival and Recovery from Disruptions*. Edited by A. P. Sage, Wiley Series in Systems Engineering and Management. Hoboken, NJ, USA: John Wiley & Sons.

Discussion

This term is an a accumulation of terms defined by Woods (2006).

Chaos (glossary)

(1) A state of disorder or unpredictability. (Oxford English Dictionary)

(2) A chaotic system has elements which are not interconnected and behave randomly with no adaptation or control. (Oxford English Dictionary)

(3) Chaos theory is applied to certain types of dynamic system (e.g. the weather) which, although they have structure and relationships, exhibit un-predictable behavior. These systems are deterministic; their future behavior is fully determined by their initial conditions with no random elements involved. However, their structure is such that (un-measurably) small perturbations in inputs or environmental conditions may result in unpredictable changes in behavior. This behavior is known as deterministic chaos, or simply chaos. (Kellert, 1993)

Sources

(1) and (2) *Oxford English Dictionary*. s.v. "Chaos."

(3) Kellert, S. 1993. *In the Wake of Chaos: Unpredictable Order in Dynamical Systems.* Chicago, IL, USA: University of Chicago Press. p. 32. ISBN 0-226-42976-8.

Discussion

(1) and (2) are the general usage definitions in which chaos means random and unconnected, e.g. not a system.

(3) is a mathematical definitions of a class of natural systems which appear chaotic, but have underlying mathematical order them.

Closed System (glossary)

> *A system which has no interactions with its environment.* (von Bertalanffy 1968)

Sources

von Bertalanffy, L. 1968. *General system theory: Foundations, Development, Applications.* Revised ed. New York, NY, USA: George Braziller.

Discussion

Discussion

None.

SEBOK v. 2.2, released 15 June 2020

Cohesion (glossary)

(1) *The attribute of a system that allows it to operate before, during, and after an encounter with a threat.* (Hitchins 2009)

(2) *The manner and degree to which the tasks performed by a single software module are related to one another.* (ISO/IEC/IEEE 2010)

(3) *The act or state of cohering, uniting, or sticking together.* (Dictionary.com 2012)

Sources

(1) Hitchins, D. 2009. "What Are The General Principles Applicable to Systems?" INCOSE *Insight* 12 (4) (Dec 2009): 59-63.

(2) ISO/IEC/IEEE. 2010. *Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab)*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2010.

(3) Dictionary.com. 2012. "Cohesion." Available at http://dictionary.reference.com/browse/cohesion [1].

Discussion

In systems engineering, cohesion refers both to the property of natural and social systems that similar elements are attracted to each other and to ability to operate in a threat environment. The context determines which definition is appropriate.

References

[1] http://dictionary.reference.com/browse/cohesion

Competency (glossary)

An observable, measurable set of skills, knowledge, abilities, behaviors, and other characteristics an individual needs to successfully perform work roles or occupational functions. Competencies are typically required at different levels of proficiency depending on the specific work role or occupational function. Competencies can help ensure individual and team performance aligns with the organization's mission and strategic direction. (OPM 2014)

a measure of an individual's ability in terms of their knowledge, skills, and behavior to perform a given role (Holt and Perry, 2011)

Source

U.S. Office of Personnel Management (OPM), Human Capital Assessment and Accountability Framework (HCAAF) Resource Center, "Glossary". http:/ / www. opm. gov/ hcaaf_resource_center/ glossary. asp [1] Last accessed June, 2015.

Holt, Jon, and Perry, Simon,*A Pragmatic Guide to Competency, Tools, Frameworks, and Assessment.*BCS, The Chartered Institute for IT, Swindon, UK, 2011.

Discussion

There is disagreement in the literature on whether competency is only for individuals or if the term competency can be used at the team, project, and enterprise level.

Discussion

None.

Complexity (glossary)

(1) A measure of how difficult it is to understand how a system will behave or to predict the consequences of changing it (Sheard and Mostashari 2009)

(2) The degree to which a system's design or code is difficult to understand because of numerous components or relationships among components (ISO/IEC 2009)

(3) A complex system has elements, the relationship between the states of which are weaved together so that they are not fully comprehended, leading to insufficient certainty between cause and effect (INCOSE 2021)

Source

(1) Sheard, S.A. and A. Mostashari. 2009. "Principles of Complex Systems for Systems Engineering". *Systems Engineering*, 12(4): 295-311.

(2) ISO/IEC. 2009. "Systems and Software Engineering Vocabulary (SEVocab)" - ISO/IEC 24765. in International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) [database online]. Geneva, Switzerland, 2009 [cited December 21 2009]. Available from http:// / pascal. computer. org/ sev_display/ index. action.

(3) A complexity Primer for systems Engineers, Revision 1, 2021.

Discussion

Complexity is a common property of engineered systems and occurs when there is no simple relationship between what an individual element does and what the system as a whole will do, and when the system includes some element of adaptation or problem solving to achieve its goals in different situations. It can be affected by objective attributes of a system such as by the number, types of and diversity of system elements and relationships, or by the subjective perceptions of system observers due to their experience, knowledge, training, or other socio-political considerations.

For a more complete discussion of complexity see the Complexity article in Part 2.

Complexity avoidance (glossary)

a system resilience principle which states that a system should not be more complex than is necessary. Jackson (2016)

Source

Jackson, Scott. 2016. "Principles for Resilient Design - A Guide for Understanding and Implementation." In IRGC Rresource Guide on Resilience, edited by I. Linkov. University of Lausanne, Switzerland: International Risk Governance Council (IRGC).

Discussion

Also called reduce complexity

Component (glossary)

(1) *an entity with discrete structure, such as an assembly or software module, within a system considered at a particular level of analysis.* (ISO/IEC 1998)

(2) *One of the parts that make up a system.* (IEEE 2008)

(3) *A set of functional services in the software, which, when implemented, represents a well-defined set of functions and is distinguishable by a unique name.* (ISO/IEC 2008)

Source

(1) ISO/IEC. 1998. *Information Technology — System and Software Integrity Levels* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC). ISO/IEC. 15026:1998. : 3.1

(2) IEEE. 2008. "IEEE Standard for Software and System Test Documentation". Institute of Electrical and Electronics Engineers (IEEE) Standards Association: IEEE 829-2008: 3.1.6

(3) ISO/IEC. 2008. "Information Technology — Software and Systems Engineering — FiSMA 1.1 Functional Size Measurement Method" Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC). ISO/IEC 29881:2008. A.4.

Discussion

In systems terms, we use component as the generic term for the level of decomposition at which system elements are no longer considered complex, and for which specialist design disciplines can be used.

Computer Simulation (glossary)

A dynamic representation of a model, often involving some combination of executing code, control/display interface hardware, and interfaces to real-world equipment. (DoD 1998)

Sources

DoD. 1998. "'DoD Modeling and Simulation (M&S) Glossary" in *DoD Manual 5000.59-M*. Arlington, VA, USA: US Department of Defense. January. P2.3.25. Available at http:/ / www. dtic. mil/ whs/ directives/ corres/ pdf/ 500059m.pdf

Discussion

None

Concept (glossary)

An abstraction; a general idea inferred or derived from specific instances. (Oxford Dictionaries Online 2012)

Sources

Oxford Dictionaries Online S.v. "Concept" Accessed February 20, 2012. http://oxforddictionaries.com/definition/concept.

Discussion

A concept is an abstraction; a general idea inferred or derived from specific instances. For example, by viewing a pet dog, one can infer that there are other dogs of that “type.” Hence, from this observation (or perhaps a set of observations) the concept of a dog is developed in one's mind. Concepts are bearers of meaning, as opposed to agents of meaning and can only be thought about, or designated, by means of a name.

Principles (glossary) depend on concepts in order to state a “truth.” Hence, principles and concepts go hand in hand; principles cannot exist without concepts and concepts are not very useful without principles to help guide the proper way to act (Lawson and Martin 2008).

Work Cited

Lawson, H., and J.N. Martin. 2008. "On the Use of Concepts and Principles for Improving Systems Engineering Practice". Proceedings of the 18th Annual International Council on Systems Engineering (INCOSE) International Symposium, 5-19 June 2008, Utrecht, The Netherlands.

Concept Definition (glossary)

> *A set of core technical activities of systems engineering in which the problem space and the needs of the stakeholders are closely examined. This consists of analysis of the problem space and definition of stakeholder needs for required services within it.* (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

System Concept Definition is a knowledge area in the SEBoK; it includes systems engineering activities which occur before any formal definition of the system-of-interest (SoI) is developed such as analysis and definition of stakeholder needs and requirements. This generally defines the problem statement which initiates a "concept stage" as discussed in INCOSE (2012). In the SEBoK, System Definition is used to discuss the detailed description of a solution system.

Work Cited

INCOSE. 2012. *Systems Engineering Handbook: A Guide for System Life Cycle Processes and Activities*, version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2.

Concept of Operations (ConOps) (glossary)

Verbal and graphic statement, in broad outline, of an organization's assumptions or intent in regard to an operation or series of operations. (ISO/IEC 2011)

Source

ISO/IEC 2011. *Systems and software engineering - Life cycle processes - Requirements engineering*. Geneva, Switzerland: International Organization for Standardization/International Electrotechnical Commissions. ISO/IEC 29148.

Discussion

The concept of operations frequently is embodied in long-range strategic plans and annual operational plans. In the latter case, the concept of operations in the plan covers a series of connected operations to be carried out simultaneously or in succession. The concept is designed to give an overall picture of the organization operations.

It provides the basis for bounding the operating space, system capabilities, interfaces and operating environment.

See also operational concept which is slightly different.

Concrete Syntax (glossary)

The symbols used to express the constructs of a language. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

There is a reference for "Concrete Syntax" in the computing domain:

"The syntax of a language including all the features visible in the source code such as parentheses and delimiters. The concrete syntax is used when parsing the program or other input, during which it is usually converted into some kind of abstract syntax tree (conforming to an abstract syntax).

In communications, concrete syntax is called transfer syntax."

The Free On-line Dictionary of Computing. Denis Howe. http://foldoc.org/(accessed: August 28, 2012).

However, this definition is not directly appropriate as the used in the SEBoK. Consequently, a definition at a higher level of abstraction than the term as used in the computing domain was created.

Concurrent (glossary)

(1) Happening at the same time as something else; operating or acting in conjunction with another. (Oxford English Dictionary Online 2012)

(2) Meeting or tending to meet at the same point; being in accordance; harmonious. (Ma, et al 2008)

(3) Concurrent engineering is a work methodology based on the parallelization of tasks (i.e. performing tasks concurrently). It refers to an approach used in product development in which functions of design engineering, manufacturing engineering and other functions are integrated to reduce the elapsed time required to bring a new product to the market.

(4) A concurrent life cycle approach applies life cycle activities in parallel to ensure the necessary relationships between them are considered within the life cycle. (Created for SEBoK)

Sources

(1) and (2) Oxford English Dictionary. s.v. "Concurrent."

(3) Ma, Y., G. Chen, & G. Thimm. 2008. "Paradigm Shift: Unified and Associative Feature-based Concurrent Engineering and Collaborative Engineering." *Journal of Intelligent Manufacturing.* DOI 10.1007/s10845-008-0128-y, Springer Science+Business Media

(4) This definition was developed for the SEBoK.

Discussion

(1) and (2) are dictionary definitions encapsulating the key ideas of things down at the same time, but within some common cause and joint end result.

(3) comes form the production world, where the idea of concurrency is used to both shorten delivery time and improve quality by putting activities in parallel which need to work closely together.

(4) is the more general lifecycle concept building on these ideas.

Concurrently (glossary)

> (1) *Two or more activities occurring within the same interval of time, achieved either by interleaving the activities or by simultaneous execution. (ISO/IEC/IEEE 2010)*
>
> (2) *A problem, process, system, or application in which many activities are happening in parallel, the order of incoming events is not usually predictable, and events often overlap.* (ISO/IEC/IEEE 2010)

Sources

(1) and (2) ISO/IEC/IEEE. 2010. *Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab)*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2010.

Discussion

Modified from the definition of 'concurrent'.

Configuration (glossary)

The functional and physical characteristics of hardware or software as set forth in technical documentation or achieved in a product (ISO 24765, 2010)

Source

ISO/IEC/IEEE. 2010. *Systems and Software Engineering -- Vocabulary (SEVocab)* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronic Engineers (IEEE) 2009 ISO/IEC/IEEE 24765:2010 [database online]. Available from http://pascal.computer.org/sev_display/index.action.

Discussion

None.

Configuration Management (glossary)

A discipline applying technical and administrative direction and surveillance to: identify and document the functional and physical characteristics of a configuration item, control changes to those characteristics, record and report change processing and implementation status, and verify compliance with specified requirements. (ISO/IEC/IEEE 2010)

Source

ISO/IEC/IEEE. 2010. *Systems and Software Engineering -- Vocabulary (SEVocab)* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronic Engineers (IEEE) 2009 ISO/IEC/IEEE 24765:2010 [database online]. Available from http://pascal.computer.org/sev_display/index.action.

Discussion

None.

Constraint (glossary)

(1) A restriction, limit, or regulation imposed on a product, project, or process. (ANSI/EIA 1998)

(2) A type of requirement or design feature that cannot be traded off. (ANSI/EIA 1998)

Sources

(1) and (2) ANSI/EIA. 1998. *ANSI/EIA 632\Processes for Engineering a System.* Philadelphia, PA, USA: American National Standards Institute (ANSI)/Electronic Industries Association (EIA), ANSI/EIA 632-1998.

Discussion

None.

Control (glossary)

(1) In engineering, the monitoring of system output to compare with expected output and taking corrective action when the actual output does not match the expected output. (ISO/IEC 2010)

(2) In engineering, the monitoring of system output to compare with expected output and taking corrective action when the actual output does not match the expected output. (ISO/IEC 2010)

(3) Comparing actual performance with planned performance, analyzing variances, assessing trends to effect process improvements, evaluating possible alternatives, and recommending appropriate corrective action as needed. (PMI 2008)

(4) In an IDEF0 model, a condition or set of conditions required for a function to produce correct output. (IEEE 1998)

(5) In risk management, the formal name for the mitigation risk handling option. (DAU 2003a)

Source

(1) and (2) ISO/IEC/IEEE. 2010. *Systems and Software Engineering -- Vocabulary (SEVocab)* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronic Engineers (IEEE) 2009 ISO/IEC/IEEE 24765:2010 [database online]. Available from http://pascal.computer.org/sev_display/index.action.

Discussion

None.

Coordinate (glossary)

Insert definition here. (Reference YEAR)

Source

Insert full source info (Author Last, FI. YEAR. TITLE. Publisher. URL)

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Cost (glossary)

In the context of systems engineering, a cost is an amount expressed in a given currency related to the value of a system element, a physical interface, a physical architecture. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

None.

Critical Design Review (CDR) (glossary)

A review conducted to verify that the detailed design of one or more configuration items satisfy specified requirements; to establish the compatibility among the configuration items and other items of equipment, facilities, software, and personnel; to assess risk areas for each configuration item; and, as applicable, to assess the results of producibility analyses, review preliminary hardware product specifications, evaluate preliminary test planning, and evaluate the adequacy of preliminary operation and support documents. (ISO/IEC 2010)

Source

ISO/IEC. 2010. *Systems and Software Engineering Vocabulary (SEVocab)* - ISO/IEC 24765. in International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) [database online]. Geneva, Switzerland, 2010. Available from http://pascal.computer.org/sev_display/index.action.

Discussion

None.

Critical Systems Thinking (glossary)

> *Critical systems thinking (CST) or critical management science provides an approach to help select between hard system and soft system methods.* (Jackson, 1985)

Sources

Jackson, M. 1985. "Social Systems Theory and Practice: The Need for a Critical Approach." *International Journal of General Systems 10*: 135-151.

Discussion

None.

Culture (glossary)

> *The basic values, norms, beliefs, and practices that characterize the functioning of a particular institution.* (NASA 2003)

Source

NASA. 2003. *Columbia Accident Investigation Report.* R. Godwin. Ed. Washington, DC, USA: National Aeronautics and Space Administration (NASA). p. 101.

Discussion

This is an authoritative source endorsed by NASA on the subject of culture.

Customer (glossary)

> *The organization or person that receives a product or service.* (ISO/IEC/IEEE 2015)

Sources

ISO/IEC/IEEE. 2015. *Systems and Software Engineering -- System Life Cycle Processes*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions. ISO/IEC/IEEE 15288:2015.

Discussion

There are 9 definitions in the SEVOCAB repository of glossary entries. Several of these are very specific to particular standards. See http://www.computer.org/sevocab for more detail.

Cyber-Physical Systems (glossary)

> *(1) Cyber-Physical Systems (CPS) are integrations of computation with physical processes. Embedded computers and networks monitor and control the physical processes, usually with feedback loops where physical processes affect computations and vice versa.* (Lee 2008, 363)
>
> *(2) ... in the past the science of computation has systematically abstracted away the physical world and vice versa. It is time to construct a Hybrid Systems Science that is simultaneously computational and physical, providing us with a unified framework for robust design flow with multi-scale dynamics and with integrated wired and wireless networking for managing the flows of mass, energy, and information in a coherent way.* (Sha et al.)
>
> *(3) Cyber-physical systems (CPS) are physical and engineered systems whose operations are monitored, coordinated, controlled and integrated by a computing and communication core.* (Rajkumar et al. 2010)

Source

(1) Lee, Edward A. "Cyber physical systems: Design challenges". *Object Oriented Real-Time Distributed Computing (ISORC)*, 2008 11th IEEE International Symposium on. 363-369. 2008.

(2) L. Sha, S. Gopalakrishnan, X. Liu and Q. Wang. "Cyber-Physical Systems: A New Frontier" *Sensor Networks, Ubiquitous and Trustworthy Computing*, 2008. SUTC '08. IEEE International Conference on, Taichung, 2008.

(3) Ragunathan (Raj) Rajkumar, Insup Lee, Lui Sha, and John Stankovic. "Cyber-physical systems: the next computing revolution". In Proceedings of the 47th *Design Automation Conference (DAC '10)*. ACM, New York, NY, USA, 731-736. 2010.

Discussion

Cyber-Physical Systems is still an emerging topic with no precise and universal agreed definition. Listed above are three descriptions of Cyber-Physical Systems from frequently referenced publications.

Cybernetics (glossary)

The study and modeling of communication, regulation and control in systems. (Wiener 1948)

Sources

Wiener, N. 1948. *Cybernetics: or Control and Communication in the Animal and the Machine.* Cambridge, MA, USA: The Massachusetts Institute of Technology Press.

Discussion

Cybernetics studies the flow of information through a system and how information is used by the system to control itself through feedback mechanisms. Early work in cybernetics in the 1940 was applied to electronic and mechanical networks, and was one of the disciplines used in the formation of early systems theory. It has since been used as a set of founding principles for all of the significant system disciplines.

Cycle (glossary)

A series of events that are regularly repeated in the same order; or move in or follow a regularly repeated sequence of events. (Oxford English Dictionary, 2020)

Sources

Oxford English Dictionary. 2020. s.v. "Cycle". “Cycles define and make things. Equally things contain Cycles.” (Volk 1995) “A Temporal Pattern” (Mobus and Kalton 2015)

Discussion

Movement and evolution are fundamental in the dynamics of nature and thus cycles are evident, almost or even absolutely, everywhere. https://en.wikipedia.org/wiki/List_of_cycles

Due to its generality, Cycle is a key concept for Systemists, in our communication, in our thinking and our engagement with systems. The repetition of natural law and associated behaviour in mechanical systems, and other examples of objective-subjective or system-context cycles are important in systems science. Cyclical phenomena are studied in several different ways in different sciences, e.g. dynamics, biology, sociology, cosmology etc.

Works Cited

D

Data Center (glossary)

> *The data center is the department in an enterprise that houses and maintains back-end information technology (IT) systems and data stores—its mainframes, servers and databases.* (Gartner 2012)

Source(s)

Gartner 2012. "Data Center". Accessed 25 July 2012. Available at: http:/ / www. gartner. com/ it-glossary/ data-center/.

Discussion

In the days of large, centralized information technology (IT) operations, this department and all the systems resided in one physical place, hence the name data center.

With today's more distributed computing methods, single data center sites are still common, but are becoming less so. The term continues to be used to refer to the department that has responsibility for these systems, no matter how dispersed they are.

Decision Gate (glossary)

> *(1) A decision gate is an approval event (often associated with a review meeting). Entry and Exit criteria are established for each decision gate; continuation beyond the decision gate is contingent on the agreement of the decision-makers.* (INCOSE 2011 p 362)
>
> *(2) A preplanned management event in the project cycle to demonstrate accomplishments, approve and baseline results, and approve the approach for continuing the project. (Also known as a control gate.)* (Forsberg 2005, p 428)

Sources

(1) INCOSE. 2011. Systems Engineering Handbook, version 3.2.2. INCOSE-TP-2003-002-03.2.2.

(2) Forsberg, K., H. Mooz, H. Cotterman. 2005. Visualizing Project Management, 3rd Ed., Hoboken, NJ, USA: John Wiley and Sons.

Discussion

(1) The definition provided in the INCOSE Handbook is built on the language in ISO/IEC 15288:2015. Consequently it is at a high level of abstraction.

(2) The definition in "Visualizing Project Management" is tied to the project cycle and the project management issues related to it. The intent is to bring the systems engineering activities into the project context.

Decision Management (glossary)

Analysis of possible decisions using a formal evaluation process (glossary) that assesses identified alternatives against established criteria. (Created for SEBoK)

Source

This definition was developed for SEBoK v 1.0.

Discussion

Stakeholders should have input to the guidelines used to determine which issues should be included in the analysis.

Defense in depth (glossary)

> A system resilience principle that states that a system should be capable of having two or more ways to address a single vulnerability. Jackson (2016)

Source

Jackson, Scott. 2016. "Principles for Resilient Design - A Guide for Understanding and Implementation." In IRGC Resource Guide on Resilience, edited by I. Linkov. University of Lausanne, Switzerland.

Discussion

Also called layered defence

Demonstration (glossary)

(1) A dynamic analysis technique that relies on observation of system or component behavior during execution, without need for post-execution analysis, to detect errors, violations of development standards, and other problems. (ISO/IEC 2010)

(2) A qualitative exhibition of functional performance against a set of test activities with pre-determined system stimuli designed to illustrate appropriate response or to show that operators can perform their allocated functions, usually accomplished with no or minimal instrumentation or test equipment. (Created for SEBoK)

Source

(1) ISO/IEC. 2010. *Systems and Software Engineering Vocabulary (SEVocab)* - ISO/IEC 24765. in International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) [database online]. Geneva, Switzerland, 2010. Available from http://pascal.computer.org/sev_display/index.action.

(2) This definition was developed for the SEBoK.

Discussion

None.

Derived Requirement (glossary)

Constraint stated during the design activities which arise as a result of the selected solution (for example, a necessary mean or resource related to a technology, or an interface between two components of different sub-systems). (Faisandier 2012)

Source

(1) Faisandier, A. 2012. *Systems Architecture and Design*. Belberaud, France: Sinergy'Com.

(2) INCOSE. 1998. *INCOSE SE Terms Glossary,* version 0. Accessed September 12, 2012.

Discussion

None.

Descriptive Model (glossary)

> *(1) A model that describes things as they are.* (Turban, et al 2010)
>
> *(2) That depicts or describes how things actually work, and answers the question, "What is this?"* (BusinessDictionary 2012)

Sources

(1) Turban, E., R. Sharda, and D. Delen. 2010. *Decision Support and Business Intelligence Systems*, 9th ed. Upper Saddle River, NJ, USA: Prentice-Hall.

(2) BusinessDictionary.com. 2012. s.v. "Descriptive Model." http:/ / www. businessdictionary. com/ definition/ descriptive-model.html (accessed: September 12, 2012).

Discussion

Typical descriptive models may include those that describe the functional or physical architecture of a system, or the three dimensional geometric representation of a system.

Design (glossary)

> *(System) design includes activities to create concepts and models, and/or to conceive something (a system / a solution that answers an intended purpose) based on or using principles and concepts; the outcome of design activities is a coherent and purposeful set of models or representations using defined constructs and patterns (that implement principles and concepts).* (ISO/IEC/IEEC 2009)

Sources

ISO/IEC/IEEE. 2009. *Systems and Software Engineering - System and Software Engineering Vocabulary*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2009.

Discussion

The definition provided above is a synthesis and adapted to systems of several understanding to the term "Design" as found in the sources cited.

In ISO/IEC/IEEE 24765:2010 - *Systems and software engineering – Vocabulary*, "design" means:

1. the process of defining the architecture, components, interfaces, and other characteristics of a system or component;
2. the result of the process in (1);
3. the process of defining the software architecture, components, modules, interfaces, and data for a software system to satisfy specified requirements;
4. the process of conceiving, inventing, or contriving a scheme for turning a computer program specification into an operational program;
5. activity that links requirements analysis to coding and debugging; or
6. stage of documentation development that is concerned with determining what documentation will be provided in a product and what the nature of the documentation will be (ISO/IEC 26514:2008 Systems and software engineering--requirements for designers and developers of user documentation, 4.13)

Design Factor (glossary)

> *A solution parameter, characteristics, or relationship that influences the design at the system level.* (Singer et al. 2017)

Source

Singer, D., J. Strickland, N. Doerry, T. McKenney, and C. Whitcomb. 2017. “Set-Based Design.” *SNAME T&R Bulletin SNAME (mt) Marine Technology Technical and Research Bulletin.*

Discussion

None.

Design Life (glossary)

The design life of a component or system is the period of time during which the item is expected by its designers to work within its specified parameters; in other words, the life expectancy of the item. It is the length of time between placement into service of a single item and that items on-set of wear-out. (wikipedia 2012)

Source

Wikipedia contributors. "Design life," *Wikipedia*, The Free Encyclopedia, http:/ / en. wikipedia. org/ w/ index. php?title=Design_life&oldid=470916040 (accessed September 13, 2012).

Discussion

None.

Design Property (glossary)

> *A characteristic obtained during design through allocation of requirements, or estimate, analysis, study, calculation, simulation, etc.* (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

A design property is associated to a system element, a physical interface, a physical architecture. If the designed element complies with a requirement, the design property should equal the requirement. Otherwise one has to identify the difference or non conformance which treatment could conclude to modify the requirement, or the design, or identify a deviation.

DevOps (glossary)

> *The combination of cultural philosophies, practices, and tools that increases an organization's ability to deliver applications and services at high velocity: evolving and improving products at a faster pace than organizations using traditional software development and infrastructure management processes.* (Amazon)

Source

Available at: Amazon https://aws.amazon.com/devops/what-is-devops/.

Discussion

None.

Digital Elevation Model (glossary)

Insert definition here. (Reference YEAR)

Source

Insert full source info (Author Last, FI. YEAR. TITLE. Publisher. URL)

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Digital Terrain Model (DTM) (glossary)

A digital elevation model (DEM) that incorporates the elevation of important topographic features on the land.

Note to entry: DTMs are comprised of mass points and breaklines that are irregularly spaced to better characterize the true shape of the bare-earth terrain. The net result of DTMs is that the distinctive terrain features are more clearly defined and precisely located, and contours generated from DTMs more closely approximate the real shape of the terrain.

Sources

ISO TC211. "Digital terrain model." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 1936. Available at: https://isotc211.geolexica.org/concepts/1936/ [1].

Discussion

None.

References

[1] https://isotc211.geolexica.org/concepts/1936/

Digital Twin (glossary)

A high-fidelity model of the system, which can be used to emulate the actual system. (SEBoK Original)

Source

SEBoK original.

Discussion

None.

SEBoK v. 2.1, 31 October 2019

Disposal (glossary)

The process of removing a system or component, ensuring proper handling of any environmentally sensitive materials, and sending the remainder to surplus storage or sale. (Mooz, et al 2003)

Source

Mooz, H., Forsberg, K., Cotterman, H. 2003. *Communicating Project Management.* Hoboken, NJ, USA: John Wiley and Sons. p. 159.

Discussion

It is critical to consider disposal from the very outset of the project. It is also not enough to consider only the end-of-life of the product(s) produced during the project. The process of producing a product will have byproducts which need to be managed and properly disposed of.

Disruption (glossary)

An interruption in the functionality of a system. Disruptions may be either internal or external. Internal disruptions may be due to human error, software error, or component failure. External disruptions may be caused by hostile attacks or natural phenomena, such as earthquakes, tsunamis, or hurricanes. Disruptions may also result from loss of resources (external) or from "system" errors, that is, failures caused by the interaction of two or more components that performed as designed (internal). (Jackson 2010)

Source

Jackson, S. 2010. *Architecting Resilient Systems: Accident Avoidance and Survival and Recovery from Disruptions.* Hoboken, NJ, USA: John Wiley and Sons. p. 39-53.

Discussion

This book has a good discussion of the concept of disruptions. The word is used in other sources such as Hollnagel et al (Resilience Engineering: Concepts and Precepts, Ashgate Publishing Ltd, 2006, UK) and various government document.

Diversity (glossary)

> *The range of human differences, encompassing the characteristics that make one individual or group different from another. Diversity includes, but is not limited to, the following characteristics: race, ethnicity, culture, gender identity and expression, age, national origin, religious beliefs, work sector, physical ability, sexual orientation, socioeconomic status, education, marital status, language, physical appearance, and cognitive differences.* (ABET 2020)

Source

ABET. 2020. "Diversity, Equity, and Inclusion." Accreditation Board for Engineering and Technology (ABET) website. https://www.abet.org/about-abet/diversity-equity-and-inclusion/Accessed: December 2020.

Discussion

See related terms

Domain (glossary)

> *A problem space.* (IEEE 2010)

Sources

IEEE. 2010. *Standards for Information Technology.*. New York, NY, USA: Institute of Electrical and Electronics Engineers (IEEE), IEEE 1570-2010.

Discussion

Common usage includes "domain of application" and "domain engineering." In both cases a specific problem space is implied.

Drift Correction (glossary)

> *A resilience design principle that states that the drift of a system into a region of increasing risk should be monitored and appropriate responses should be formulated and executed* – adapted from (Leveson et al. 2006)

In a resilience context according to Jackson and Ferris (2013) drift correction is a component principle of the adaptability grouping.

Sources

Leveson, N., N. Dulac, D. Zipkin, Cutcher-Gershenfeld, J. Carroll, and B. Barrett. 2006. "Engineering Resilience into a Safety-Critical System." In *Resilience Engineering: Concepts and Precepts,* edited by E. Hollnagel, D. D. Woods and N. Leveson. Aldershot, UK: Ashgate Publishing Limited.

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Discussion

This is a key resilience design principle. Although the definition above implies a gradual drift into a high risk state, it can also be interpreted to imply an immediate impending danger as was done by (Jackson 2010).

Jackson, S. 2010. *Architecting Resilient Systems: Accident Avoidance and Survival and Recovery from Disruptions.* Edited by A. P. Sage, Wiley Series in Systems Engineering and Management. Hoboken, NJ, USA: John Wiley & Sons.

Drift Correction (glossary)

> *A resilience design principle that states that the drift of a system into a region of increasing risk should be monitored and appropriate responses should be formulated and executed* – adapted from (Leveson et al. 2006)

In a resilience context according to Jackson and Ferris (2013) drift correction is a component principle of the adaptability grouping.

Sources

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Discussion

This is a key resilience design principle. Although the definition above implies a gradual drift into a high risk state, it can also be interpreted to imply an immediate impending danger as was done by (Jackson 2010).

Jackson, S. 2010. *Architecting Resilient Systems: Accident Avoidance and Survival and Recovery from Disruptions.* Edited by A. P. Sage, Wiley Series in Systems Engineering and Management. Hoboken, NJ, USA: John Wiley & Sons.

Dualism (glossary)

> *(1) The division of something conceptually into two opposed or contrasted aspects, or the state of being so divided.* (Stanford Encyclopedia of Philosophy 2011)
>
> *(2) In the history of thought, the idea that, for some particular domain, there are two fundamental kinds or categories of things or principles.* (Stanford Encyclopedia of Philosophy 2011)

Sources

Stanford Encyclopedia of Philosophy. 2011. s.v. "Dualism." Accessed on September 11, 2012. Available at http://plato.stanford.edu/entries/dualism/.

Discussion

The yin yang concept in Chinese philosophy emphasizes the interaction between dual elements and their harmonization, ensuring a constant dynamic balance often through a cyclic dominance of one element and then the other, such as day and night (see Principles of Systems Thinking)

E

E-Services (glossary)

A collection of network-resident software services accessible via standardized protocols, whose functionality can be automatically discovered and integrated into applications or composed to form more complex services. (Hull et al. 2003)

Sources

Hull, R., M. Benedikt, V. Christiphides, J. Su. 2003. "E-Services: A Look Behind the Curtain." Proceedings of Symposium on Principles of Database Systems, 9-12 June, 2003, San Diego, CA.

Discussion

None.

Effectiveness (glossary)

(1) A systems effectiveness is a measure of its ability to perform the functions necessary to achieve goals or objectives, defined as the product of the number of combinations of behavior to reach a function and the efficiency of each combination. (Ackoff 1971)

(2) A combination of performance (how well a function is done in ideal conditions), availability (how often the function is there when needed) and survivability (how likely is it that the system will be able to use the function fully). (Hitchins 2007)

Sources

Ackoff, R.L. 1971. *Towards a System of Systems Concepts."* Management Science. *17(11).*

Hitchins, D. 2007. *Systems Engineering: A 21st Century Systems Methodology.* New York, NY, USA: Wiley

Discussion

(1) is a system science definition associated with the difference between behavior as system actions and function as combinations of behavior to provide external outocmes. Effectiveness is a measure of how well the system achieves it outcomes.

(2) is the systems engineering definiton, relating effectiveness to achieving stakeholder needs.

Element (glossary)

Please see system element.

Ellipsoid (glossary)

> *Either (1) a geometric reference surface embedded in 3D Euclidean space represented by an ellipsoid of revolution where the rotation is about the polar axis, or (2) a reference ellipsoid, which is a geometric reference surface embedded in 3D Euclidean space formed by an ellipse that is rotated about a main axis.*

Notes to Entry:

- For definition (1):

1. For the Earth, the rotation is about the polar axis. This results in an oblate ellipsoid with midpoint of the foci located at the nominal center of the Earth.
2. The two usual algorithms for latitude on an ellipsoid and on a sphere (such as used in spherical coordinates) are only equivalent if the ellipsoid is a sphere, having all radii equal in all directions. The problem is that a radial line from the center of a general ellipsoid does not always cross the surface of the ellipsoid orthogonally. In general, planar slices through the center do not intersect the surface orthogonally, and therefore the curves that correspond to the great circles of a sphere are not geodesics on the ellipsoid.
3. The topology of the ellipsoid is inherited from the $\mathbb{R}^3$ space in which it is embedded. The difference is that metrics such as distance and direction on the ellipsoid are restricted to curves wholly on the surface and vectors tangent to the surface.

- For definition (2):

1. For the Earth, the ellipsoid is bi-axial with rotation about the polar axis. This results in an oblate ellipsoid with the midpoint of the foci located at the nominal center of the Earth.

Discussion

None.

Ellipsoidal Height or Geodetic Height (glossary)

> *Ellipsoidal height, also known as geodetic height* h*, is the distance of a point from the reference ellipsoid along the perpendicular from the reference ellipsoid to this point, positive if upwards or outside of the reference ellipsoid.*

Notes to Entry:

1. Only used as part of a three-dimensional ellipsoidal coordinate system or as part of a three-dimensional Cartesian coordinate system in a three-dimensional projected coordinate reference system, but never on its own.
2. Ellipsoidal height and geodetic height are registered with the ISO as two separate terms, but in practice are frequently used synonymously.

Sources

ISO TC211. "Ellipsoidal height." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 2406. Available at: https://isotc211.geolexica.org/concepts/2406/.

Discussion

None.

Emergence (glossary)

> *The principle that whole entities exhibit properties which are meaningful only when attributed to the whole, not to its parts. Every model of a human activity system exhibits properties as a whole entitity which derive from its component activities and their structure, but cannot be reduced to them.* (Checkland 1999)

Source

Checkland, P. B. 1999. *Systems Thinking, Systems Practice*. Chichester, UK: John Wiley & Sons Ltd.

Discussion

There are other views of emergence which are not captured in Checkland's definition. Emergence has two aspects to it (like two sides of the same coin): One, for a given object, some of its properties may be identified as emergent with respect to a description of the object in terms of interacting elements. Two, if a set of given elements are allowed to interact, the resulting system may have properties that are not found in any one of the elements; these are the properties emerging as a result of the interaction and are therefore called the emergent properties of the system. In the first case, emergence arises as a result of the mode of description (no physical action or change involved), in the second case emergence arises as a result of a physical action or change (making the objects interact).

Emergent Behavior (glossary)

1. Behavior that is "in the process of coming into being or becoming prominent." (Apple 2011)

2. Behavior that is "arising unexpectedly or as a new or improved development." (Webster 1980)

Source(s)

(1) Apple. 2011. "On-line Dictionary", version 2.2.3, 2005 - 2011

(2) Webster's New World Dictionary. 1980. s.v. "Emergent Behavior."

Discussion

None.

Emergent Property (glossary)

Property of a system that is meaningful only at higher levels of the organization of a system and results from increased complexity at higher levels -- adapted from (Checkland 1999, p. 78)

Sources

Checkland, P. 1999. *Systems Thinking, Systems Practice*. New York: John Wiley & Sons.

Discussion

Also, see definition of *emergence* and the Emergence article.

Enabling System (glossary)

A system that complements a system-of-interest during its life cycle stages, but does not necessarily contribute directly to its function during its operation stage. (INCOSE 2012)

Source

INCOSE. 2012. *Systems Engineering Handbook,* version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2.

Discussion

An enabling system may support a System-of-Interest at any stage of its life. This may include direct maintainence and support systems, test, installation or training systems or project organization enabling systems such as project teams or information resources. See Enabling Systems Engineering.

Encapsulation (glossary)

> *(1) As a process, encapsulation means the act of enclosing one or more items within a (physical or logical) container.* (Parnas 1972).
>
> *(2) A software development technique that consists of isolating a system function or a set of data and operations on those data within a module and providing precise specifications for the module.* (IEEE 1990).

Sources

(1) Parnas,D. 1972. "On the Criteria To Be Used in Decomposing Systems Into Modules," *Communications of the ACM,* 5:(12) (December 1972) 1053-1058.

(2) IEEE. 1990. *Standard Glossary of Software Engineering.* Washington, DC, USA: Institute of Electrical and Electronics Engineers (IEEE). IEEE 610.12-1990.

Discussion

Much of the thinking in software engineering on abstraction, information hiding, and encapsulation was shaped by the classic 1972 paper by David Parnas. Parnas recommended that design decisions be encapsulated, especially decisions that are likely to change. This approach limits the rippling effect of a change in one element of a system so it does not result in changes spreading throughout the system.

Developments in Modular systems and in Object Oriented Programming and Design have largely been based on these ideas.

More generally System Encapsulation encloses system elements and their interactions from the external environment, and usually involves a system boundary that hides the internal from the external (see Concepts of Systems Thinking). Encapsulation can occur naturally in complex systems, as in the organs of the human body, or it can be used as a design strategy in man made systems.

Engineered System (glossary)

(1) An open, concrete system of technical or socio-technical elements which is the focus of a SE Life Cycle (glossary). Its characteristics include being created by and for people, having a purpose and satisfying key stakeholders' value propositions when considered as part of a broader System Context (glossary) . (Created for SEBoK)

(2) An engineered system is a system designed or adapted to interact with an anticipated operational environment to achieve one or more intended purposes while complying with applicable constraints.

Sources

(1) This definition was created for SEBoK v. 1.0.

(2) INCOSE Fellows Briefing to INCOSE Board of Directors, January 2019.

Discussion

Definition (1) was adapted from the INCOSE Systems Engineering Handbook and systems science literature on open, concrete systems. See the Engineered Systems topic.

It is related to the definition proposed by Bartolomei et al (2006):

> *An engineering system is a complex socio-technical system that is designed, developed, and actively managed by humans in order to deliver value to stakeholders.*

Definition (2) was created by the INCOSE Fellows Initiative on System and Systems Engineering Definitions. This was established in 2016, to review current INCOSE definitions of SYSTEM and SYSTEMS ENGINEERING and to recommend any changes necessary to align the definitions to a) current practice, and b) the aspirations of INCOSE's 2025 Vision. At the January 2019 INCOSE Board of Directors meeting, a new INCOSE definition for "system" was approved and is given above.

Expanding on this definition, the INCOSE Fellows state:

> Thus, an "engineered system" is a system – not necessarily a technological one - which has been or will be "systems engineered" for a purpose.

Engineering (glossary)

(1) *The application of scientific knowledge to practical problems, or the creation of useful things. The traditional fields of mechanical engineering, electrical engineering, etc. are included in this definition.* (Checkland 1999)

(2) *To (cleverly) arrange for something to happen.* (Checkland 1999)

Source

Checkland, P. B. 1999. *Systems Thinking, Systems Practice*. Chichester, UK: John Wiley & Sons Ltd.

Discussion

None.

Engineering Change Management (glossary)

1. Change Management: The comprehensive evaluation and approval or disapproval of a change that takes into consideration all effects of the change. (Mooz 2003, p 116, 164)

2. Engineering Change: An alteration in the configuration of a configuration item or other desiginated item after formal establishment of its configurement identification. (Kossiakoff 2003, p 448)

Source(s)

Kossiakoff, A., and W. N. Sweet, 2003. *Systems Engineering: Principles and Practice*, J. Wiley & Sons, New Jersey. p. 448.

Mooz, H., K. Forsberg, and H. Cotterman, 2003. *Communicating Project Management*, J. Wiley & Sons, New Jersey. p. 116, 164.

Discussion

Engineering Change Management focuses on technical changes, or the technical aspect of a change, versus the business or budgetary aspect of the change. An engineering change notice is the formal release of an engineering revision to an approved baseline.

Engineering Change Proposal (ECP) (glossary)

> *An engineering change proposal (ECP) is the management tool used to propose a configuration change to a configuration item (CI) and the system's baselined performance requirements and configuration documentation established during design and development of the system* (DoD 2001)

Sources

DoD. 2001. *MIL-HDBK-61A(SE) Configuration Management Handbook*, 7 February 2001. Accessed on 11 September 2012. Available at https://acc.dau.mil/CommunityBrowser.aspx?id=142238.

Discussion

None.

Engineering Coordinate Reference System (glossary)

> *A coordinate reference system based on an engineering datum.*

Examples:

- Local engineering and architectural grids;
- coordinate reference system local to a ship or an orbiting spacecraft

Sources

ISO TC211. "Engineering coordinate reference system." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 706. Available at: https://isotc211.geolexica.org/concepts/706/ [1].

Discussion

None.

Enterprise (glossary)

(1) *one or more organizations sharing a definite mission, goals, and objectives to offer an output such as a product or service.* (ISO 15704 2000)

(2) *An organization (or cross organizational entity) supporting a defined business scope and mission that includes interdependent resources (people, organizations and technologies) that must coordinate their functions and share information in support of a common mission (or set of related missions).* (CIO Council 1999)

(3) *the term enterprise can be defined in one of two ways. The first is when the entity being considered is tightly bounded and directed by a single executive function. The second is when organizational boundaries are less well defined and where there may be multiple owners in terms of direction of the resources being employed. The common factor is that both entities exist to achieve specified outcomes.* (MOD 2004)

(4) *A complex, (adaptive) socio-technical system that comprises interdependent resources of people, processes, information, and technology that must interact with each other and their environment in support of a common mission.* (Giachetti 2010)

Source

(1) ISO 15704. 2000. *Industrial Automation Systems -- Requirements for Enterprise-Reference Architectures and Methodologies*. Geneva, Switzerland: International Organization for Standardization (ISO), ISO 15704:2000.

(2) CIO Council. 1999. *Federal Enterprise Architecture Framework (FEAF)*. Washington, DC, USA: Chief Information Officer (CIO) Council.

(3) MOD. 2004. *Ministry of Defence Architecture Framework (MODAF)*, version 2. London, UK: U.K. Ministry of Defence.

(4) Giachetti, R. E. 2010. *"Design of Enterprise Systems: Theory, Architecture, and Methods."* Boca Raton, FL, USA: CRC Press, Taylor and Francis Group.

Discussion

Definition (1) above is the SEBoK preferred definition. The focus of this definition is on purpose rather than structure, and the enterprise may be either enduring or transient, and either formally or informally constituted and governed. The simplest case of enterprise could be an individual and the largest a national or international undertaking.

Definition (2) is compatible with definition (1) and provides additional insight relevant to the practice of "enterprise architecting", which is closely related to Enterprise Systems Engineering.

Definition (3) highlights the fact that the word "enterprise" is sometimes used synonymously with "business". However in the SEBoK the term business is used to refer to a form of organization, while an enterprise often involves collaboration across organizational boundaries. Furthermore, we also use prodcut and team to refer to two other forms of an organization. An enterprise *could* be at the business level, but some enterprises are at the project or team level. Therefore, as noted above, it is better to focus on the purpose rather than structure of an "enterprise" to facilitate the more proper use and better understanding of that term.

Definition (4) highlights the socio-technical nature of the enterprise and its ability to be adaptable to changing circumstances.

Enterprise Architecture (glossary)

(1) *A rigorous description of the structure of an enterprise, its decomposition into subsystems, the relationships between the subsystems, the relationships with the external environment, the terminology to use, and the guiding principles for the design and evolution of an enterprise.* (Giachetti 2009)

(2) *A strategic information asset base, which defines the business, the information necessary to operate the business, the technologies necessary to support the business operations, and the transitional processes necessary for implementing new technologies in response to the changing business needs. It is a representation or blueprint.* (CIO Council 1999)

(3) *The formal description of the structure and function of the components of an enterprise, their interrelationships, and the principles and guidelines governing their design and evolution over time.* (MOD 2004)

(4) *A discipline for proactively and holistically leading enterprise responses to disruptive forces by identifying and analyzing the execution of change toward desired business vision and outcomes. Enterprise architecture delivers value by presenting business and IT leaders with signature-ready recommendations for adjusting policies and projects to achieve target business outcomes that capitalize on relevant business disruptions. It is used to steer decision making toward the evolution of the future state architecture.* (Gartner 2013)

(5) The practice of conducting enterprise analysis, design, planning, and implementation using a holistic approach for the successful development and execution of strategy. EA applies architecture principles and practices to guide organizations through the business, information, process, and technology changes necessary to execute their organization's strategies. (IEEE/ACM n.d. (b))

(2) CIO Council. 1999. *Federal Enterprise Architecture Framework (FEAF)*. Washington, DC, USA: Chief Information Officer (CIO) Council.

(3) MOD. 2004. *Ministry of Defence Architecture Framework (MODAF)*, version 2. London, UK: U.K. Ministry of Defence.

(4) Gartner IT Glossary. S.V. "enterprise architecture." Accessed 11 March 2013, available at: http://www.gartner.com/it-glossary/enterprise-architecture-ea/.

(5) IEEE/ACM (n.d. (b)). *Guide to the Enterprise Information Technology Body of Knowledge* article on Enterprise Architecture. Available at: http://eitbokwiki.org/Enterprise_Architecture.Accessed on May 7, 2023.

Discussion

There are many different definitions of Enterprise Architecture which vary in the content and application of the architecture and in the importance of the various components of the architecture. The five definitions shown here reflect authoritative and expert sources.

Enterprise System (glossary)

A system context for which the system-of-interest is an enterprise. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

This definition was developed to help distinguish between an enterprise and an enterprise system in the SEBoK.

Enterprise Systems Engineering (ESE) (glossary)

The application of systems engineering principles, concepts, and methods to the planning, design, improvement, and operation of an enterprise. (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

(1) To enable more efficient and effective enterprise transformation, the enterprise needs to be looked at “as a system," rather than as a collection of functions connected solely by information systems and shared facilities (Rouse 2009).

(2) "The body of knowledge for enterprise systems engineering is evolving under such titles as enterprise engineering, Business (glossary) engineering, and Enterprise Architecture (glossary). Many systems and software engineering principles are applicable to enterprise engineering, but enterprise engineering's unique complexities require additional principles. Enterprise engineering's intent is to deliver a targeted level of enterprise performance in terms of shareholder value or customer satisfaction. Enterprise systems engineering methods include modeling; simulation; total quality management; change management; and bottleneck, cost, workflow, and value-added analysis." (Joannou 2007)

(3) A useful distinction between product system design and enterprise system design is that “enterprise design does not occur at a single point in time like the design of most systems. Instead, enterprises evolve over time and are constantly changing, or are constantly being designed.” (Giachetti 2010)

Works Cited

Giachetti, R. E. 2010. *"Design of Enterprise Systems: Theory, Architecture, and Methods."* Boca Raton, FL, USA: CRC Press, Taylor & Francis Group.

Joannou, P. 2007. "Enterprise, Systems, and Software — the Need for Integration." *Computer*, IEEE, May 2007.

Rouse, W. B. 2009. "Engineering the Enterprise as a System." In *"Handbook of Systems Engineering and Management."*, eds. A. P. Sage, W. B. Rouse. 2nd ed. New York, NY, USA: Wiley and Sons, Inc.

Entropy (glossary)

> *(1) A thermodynamic quantity representing the unavailability of a system's thermal energy for conversion into mechanical work, often interpreted as the degree of disorder or randomness in the system.* (Oxford English Dictionary Online 2012)
>
> *(2) Lack of order or predictability; gradual decline into disorder.* (Oxford English Dictionary Online 2012)
>
> *(3) Entropy is the tendency of systems to move towards disorder or disorganization. Negentropy describes the forces working in a system to hold off entropy.* (Hitchins 2007)

Sources

(1) & (2) Oxford English Dictionary. 2012. s.v. "Entropy."

(3) Hitchins, D. 2007. *Systems Engineering: A 21st Century Systems Methodology*. Hoboken, NJ, USA: John Wiley & Sons.

Discussion

Entropy has a specific mathematical definition related to transfer of energy (2nd law of thermo dynamics) which in physics is also used to describing the loss of order or organisation in a system over time.

Definiton (3) is the prefered Sysem Science view, work is put into to creating or organising a system, creating structure and order. If nothing more is done, the system will loss that order over time, unless more work (or energy) is added to the system during its life. This can be seen as an analogy for management, maintenance, training, repair, etc.

Environment (glossary)

> *(1) Anything affecting a subject system or affected by a subject system through interactions with it, or anything sharing an interpretation of interactions with a subject system.* (IEEE 1175.1-2002 (R2007), 3.6)
>
> *(2) The surroundings (natural or man-made) in which the system-of-interest is utilized and supported; or in which the system is being developed, produced or retired.* (INCOSE 2010)

Source

(1) IEEE. 2002. *IEEE Guide for CASE Tool Interconnections - Classification and Description*, 1175.1-2002.

(2) INCOSE. 2010. *INCOSE Systems Engineering Handbook*, version 3.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.

Discussion

(1) is a system science definition and can be applied to any system.

(2) is an engineered system definition, and distinguishes between the different environments that exist during the life of a system.

Equity (glossary)

> *The fair treatment, access, opportunity and advancement for all people, achieved by intentional focus on their disparate needs, conditions and abilities. Achieving equity requires understanding of historical and systemic patterns of disparity to address and eliminate barriers, and remove participation gaps as part of a comprehensive strategy to achieve equitable outcomes and social justice.* (ABET 2020)

Source

ABET. 2020. "Diversity, Equity, and Inclusion." Accreditation Board for Engineering and Technology (ABET) website. https://www.abet.org/about-abet/diversity-equity-and-inclusion/Accessed: December 2020.

Discussion

See related terms

Ethics (glossary)

(1)*A system of moral principles.*(Dictionary.com 2011)

(2)*The rules of conduct recognized in respect to a particular class of human actions or a particular group, culture, etc.: e.g. medical ethics; Christian ethics; [engineering ethics].* (Dictionary.com 2011)

(3)*Moral principles, as of an individual: e.g. His ethics forbade betrayal of a confidence.* (Dictionary.com 2011)

(4)*The discipline dealing with what is good and bad and with moral duty and obligation.* (Merriam-Webster 2011)

Sources

Dictionary.com. s.v. "Ethics." Accessed July 18, 2011, http://dictionary.reference.com/browse/ethics

Merriam-Webster, Incorporated. s.v. "Ethics." accessed July 18, 2011, http:/ / www. merriam-webster. com/ dictionary/ethics

Discussion

Distinguishing between ethics and morals can seem a bit difficult. Though the two ideas are extremely closely-related, there is still a relatively simple way to keep the distinction clear. The idea of morals or morality relates closely to one's personal character and is the result of our upbringing, schooling, family and other influences leading us to know the difference between right and wrong. The term ethics, on the other hand draws more upon the idea of standards or codes of behavior. An individual's ethical responsibilities are significantly related to and guided by her profession or role in life.

Evolutionary (glossary)

> *A development method in which successive versions are produced to respond to discoveries surfaced by the previous versions. It is applied when requirements are uncertain and/or when technology experimentation is required. The alternative method is linear development.* (Forsberg, Mooz, Cotterman 2005, p 423)

Sources

Forsberg, K., H. Mooz, H. Cotterman. 2005. *Visualizing Project Management,* 3rd ed. New York, NY, USA: J. Wiley & Sons.

Discussion

There is a substantial amount of discussion on evolutionary development in the section on Life Cycle Models.

Executable System Model (glossary)

> *A model that represents the time varying behavior of a system.* (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

None.

Extended Enterprise (glossary)

> *Wider organization' representing all associated entities - customers, employees, suppliers, distributors, etc. - who directly or indirectly, formally or informally, collaborate in the design, development, production, and delivery of a product to the end user.* (BusinessDictionary.com 2012)

Source

Federation of Systems (FoS) (glossary)

A system of systems that rates high on three dimensions of autonomy, heterogeneity, and dispersion. Each component system chooses of its own accord to participate in the FOS as it sees fit. It is a "coalition of the willing." (Krygiel 1999)

Source

Krygiel, A. J. 1999. *Behind the Wizard's Curtain: An Integration Environment for a System of Systems*. Arlington, VA, USA: C4ISR Cooperative Research Program (CCRP).

Discussion

None.

Flexibility (glossary)

The system's ability to restructure itself in response to external changes or pressures. (Woods 2006)

Sources

Woods, David D. 2006. "Essential Characteristics of Resilience," In *Resilience Engineering: Concepts and Precepts*, edited by E. Hollnagel, Woods, David D., and Leveson, Nancy. Aldershot, UK: Ashgate Publlishing Limited.

Discussion

This is a key term in the context of resilience.

Form, Fit, Function, and Interface (F3I) (glossary)

(1) *A concept used for the update or upgrade of a system whereby a only a portion or subsystem of the entire system is replaced. The updated item is said to be Form/Fit/Function and interface compatible when it can be inserted into the existing system without impacting system operation.* (Created for SEBoK)

(2) *A mechanism to link design to performance requirements; i.e., replacing an item/system based on form, fit, function and interface characteristics.* (DoD 2004)

Source

(1) This definition was developed for the SEBoK.

(2) DoD. 2004. *Guidelines for Engineering, Manufacturing and Maintenance Documentation Requirements for Unique Identification (UID) Implementation,* version 1.0. Office of the Principal Deputy Under Secretary of Defense (Acquisition, Technology and Logistics). Accessed on 11 September 2012. Available at http:www.acq.osd.mil/dpap/Docs/uid/UIDEngDocGuidever4_120604.doc.

Discussion

F3I is an important concept regarding the transparency of a change to a portion of a system.

Framework (glossary)

Architectural Framework: Conventions, principles and practices for the description of architectures established within a specific domain of application and/or community of stakeholders. (ISO/IEC/IEEE 2011)

Source

ISO/IEC/IEEE. 2011. *Systems and software engineering - Architecture description*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE), ISO/IEC/IEEE 42010.

Discussion

Examples are the Generalised Enterprise Reference Architecture and Methodologies (GERAM) (ISO 15704) and the Reference Model of Open Distributed Processing (RM-ODP) (ISO/IEC 10746).

Works Cited

ISO. 2000. Industrial Automation Systems -- Requirements for Enterprise-Reference Architectures and Methodologies. Geneva, Switzerland: International Organization for Standardization (ISO). ISO 15704:2000.

SO/IEC. 1998. Information Technology — Open Distributed Processing — Reference Model: Architecture. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 10746:1998.

Function (glossary)

(1) *A system outcomes which contribute to goals or objectives. To have a function, a system must be able to provide the outcome through two or more different combinations of elemental behavior.* (Ackoff 1971)

(2) *An action, a task, or an activity performed to achieve a desired outcome.* (Hitchins 2007)

(3) *A function is defined by the transformation of input flows to output flows, with defined performance.* (Created for SEBoK)

(4) *A broad work area encompassing multiple related disciplines (e.g., Engineering, Finance, Human Resources, etc.).* (Created for SEBoK)

Source

(1) Ackoff, R.L. 1971. "Towards a System of Systems Concepts". *Management Science.* 17(11).

(2) Hitchins, D. 2007. *Systems Engineering: A 21st Century Systems Methodology*. Hoboken, NJ, USA: John Wiley & Sons.

(3) and (4) These definitions were developed for the SEBoK.

Discussion

(1) is the system science definition. All systems have behavior, but to be able to function in a certain way they must have a certain richness of behavior. For example, fight, flight or hide are behaviors; while response to external threats is a function.

(2) is the more traditional Systems Engineering definition, in which functions are identified top down based on needs and then decomposed and allocated to lower level system.

(3) is a HW/SW or human system component definition, describing a function which can be performed by a single part of the system with identified performance.

(4) is a management definiton, describing how similar functions are collected in organizational units.

Functional Architecture (glossary)

1. *A functional architecture is a set of functions and their sub-functions that defines the transformations of input flows into output flows performed by the system to achieve its mission.* (Created for SEBoK)
2. *The inter-related set of transformative processes and purposeful input-output tasks that a system performs, or can perform, on input(s) from external or internal sources in order to produce output(s) that supports the achievement of mission objectives; aspects of a system definition concerning the manner in which a system operates on, and/or in relation to, intangible and tangible inputs from the entities, users, and environments which exist around it in the surrounding system context through the transformation of inputs into outputs.* (Created for SEBoK)

Source

Definitions 1 and 2 were both developed for the SEBoK. Definition developed by BKCASE [1] for the v1.0 (2012) Logical Architecture article; Definition 2 developed by C. Singam for the v2.10 Functional Architecture article.

Discussion

Definition 1 is adapted from ISO/IEC/IEEE 24748 - 4 (past IEEE 1220, ISO/IEC 26702) as functional architecture; but it is here modified to emphasize on transformations performed. See also definition of behavioral architecture (glossary).

Works Cited ISO/IEC. 2010. *Systems and Software Engineering, Part 1: Guide for Life Cycle Management*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 24748-1:2010.

General System Theory (glossary)

General system theory (GST), attempts to formulate principles relevant to all open systems. GST is based on the idea that correspondence relationships (homologies) exist between systems from different disciplines. Thus, knowledge about one system should allow us to reason about other systems. (von Bertalanffy 1968)

Sources

von Bertalanffy, L. 1968. *General system theory: Foundations, development, applications.* Revised ed. New York, NY: Braziller.

Discussion

Ludwig von Bertalanffy developed a research approach based on open system theory (Bertalanffy 1950). He was one of a number of natural scientists who realized that the reductionist, closed system, approach could not be used to explain the behavior of an organism in its environment.

GST also implies a scientific approach, with identify laws and generalized theory to unify all science. Bertalanffy was cofounder, along with Kenneth Boulding (economist), Ralph Gerard (physiologist) and Anatol Raporport (mathematician), of the Society for General Systems Research in 1957. This group is considered by many to be the founders of System Age Thinking (Flood 1999).

Geodesic or Geodesic Line (glossary)

A curve on a surface with a zero-length tangential curvature vector.

Notes to Entry:

1. A geodesic's curvature vector is perpendicular to the surface, thus has the minimum curvature of any curve restricted to the surface. This is often defined as a minimal distance curve between two points, but this does not always suffice, since some points (especially on ellipsoids and spheres) are often joined by more than one geodesic. For example, on an ellipsoid the points with (φ, λ) = (0, 0) and (0, 180) are joined by four separate geodesic [2 polar (the shorter) and 2 equatorial]. The exponential map is only guaranteed to be one-to-one for a small area (depending on where the center is and how the surface is curved).
2. Geodesic and geodesic line are registered with the ISO as two separate terms, but in practice are frequently used synonymously.

Governance (glossary)

(1) *System by which organizations [or systems] are directed and controlled.* (ISO/IEC 2008, 1.6.2)

(2) *Organizational chains of responsibility, authority, and communication for executing measurement and control mechanisms to effectively drive the organization and enable people to perform roles their respective roles and responsibilities.* (Cantor 2006)

(3) *A decision-making process that defines the responsibility and authority of decision makers and stakeholders for identifying, defining, discussing, making, and implementing decisions in the face of complex problems, multiple stakeholders with diverse and conflicting objectives, and resource constraints. For engineering governance, the problem complexity usually includes significant technology complexity.* (Created for SEBoK)

Gravity-Related Height (glossary)

The gravity-related height 'H' is a height that is dependent on the Earth's gravity field.

Notes to Entry:

1. This refers to, amongst others, orthometric height and Normal height, which are both approximations of the distance of a point above the mean sea level, but also may include Normal-orthometric heights, dynamic heights or geopotential numbers.
2. The distance from the reference surface may follow a curved line, not necessarily straight, as it is influenced by the direction of gravity.

Sources

ISO TC211. "Gravity-related height." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 2371. Available at: https://isotc211.geolexica.org/concepts/2371/ [1].

H

Habitability (glossary)

> *Habitability is the consideration of the characteristics of systems focused on satisfying personnel needs that are dependent upon physical environment. Habitability analyzes factors of working conditions and accommodations that are necessary to sustain the morale, safety, health, and comfort of the user population that contribute directly to personnel effectiveness and mission accomplishment.* (USAF 2012)

Sources

USAF. 2012. "US Air Force HSI (Human-System Integration) 2012." Accessed on 11 September 2012. Available at http://ww3.safaq.hq.af.mil/organizations/afhsio/hsidomains.asp.

Discussion

None.

Hard System (glossary)

> *System type characterized by the ability to define purpose, goals and missions that can be addressed via engineering methodologies in attempting to optimize a solution.* (Checkland 1999)

Source

Checkland, P. B. 1999. *Systems Thinking, Systems Practice*. Chichester, UK: John Wiley & Sons Ltd.

Discussion

None.

Hardware-in-the-Loop Testing (glossary)

> *A type of dynamic simulation that includes one or more actual system components operating in conjunction with simulated components.* (Kossiakoff and Sweet 2003, 449)

Sources

Kossiakoff, A., and W. N. Sweet, 2003. *Systems Engineering: Principles and Practice*, Hoboken, NJ: J. Wiley & Sons.

Discussion

None.

Healthcare (glossary)

> *The maintenance and improvement of physical and mental health, especially through the provision of medical services.* (Oxford Dictionaries)

Source(s)

Oxford Dictionaries. *s.v.* "healthcare." Accessed February 18, 2016. http:/ / www. oxforddictionaries. com/ us/ definition/american_english/healthcare

Discussion

The term *healthcare* generally sometimes is used to refer only to the improvement of physical or mental health; i.e. to the delivery of medical care after there is an issue. This broader definition was chosen to encompass preventive approaches to healthcare as well.

Healthcare Systems Engineering (glossary)

> *The application of systems engineering or systems thinking approaches, methods, processes, and tools to healthcare systems, i.e. systems used to maintain and improve physical or mental health of individuals, as well as to population-level healthcare issues.* (Created for SEBoK)

Source(s)

Created for the SEBoK.

Discussion

Some uses of the term *healthcare systems engineering* refer to systems engineering specifically within the healthcare delivery space; i.e. the provision of health-related services by medical professionals. However, there are applications for systems engineering throughout the healthcare sector, including in the development of medical devices and pharmaceuticals, in public health, systems biology, etc. The SEBoK Authors created this definition to reflect the wider applications of systems engineering which are beginning to occur and which will grow in future.

Height (glossary)

> *The distance of a point from a chosen reference surface positive upward along a line perpendicular to that surface.*

Notes to entry:

1. A height below the reference surface will have a negative value.
2. Generalization of ellipsoidal height (h) and gravity-related height (H).
3. See also geodetic height which is used synonymously to ellipsoidal height.

Sources

ISO TC211. "Height." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 2409. Available at: https://isotc211.geolexica.org/concepts/2409/.

Discussion

None.

Heuristic (glossary)

> *Widely accepted qualitative statements that, as judged from examples, add structure to ill-defined situations* (Rechtin 1991)

Sources

Rechtin, Eberhardt. 1991. *Systems Architecting: Creating and Building Complex Systems.* Englewood Cliffs, NJ: CRC Press.

Discussion

Rechtin has at least five defintions of this term. However, they are not sufficiently different to warrant listing them all. This one is typical.

Hierarchy (glossary)

(1) A hierarchy is an arrangement of items (objects, names, values, categories, etc.) in which the items are represented as being "above," "below," or "at the same level as" one another. Levels in a hierarchy may also represent authority, control or ownership of lower levels (command structure). (Oxford English Dictionary 2012)

(2) Organisation of system elements into groups of (sub-)system wholes, based on relative strenght of element cohesion. (Simon 1962)

(3) The hierarchy principle of systems, is the consequential concept of simultaneous multiple containment of one system by many containing systems. (Checkland 1999)

(4) An abstract view of a defined system that is developed to meet some need. The system results from an analysis that decomposes a system into constituent elements at two or more levels. Often based around a defined taxonomy of levels covering System, element, Subsystem, assembly, components and parts. (INCOSE 2011)

Source

(1) Oxford English Dictionary, s.v. "Hierarchy."

(2) Simon, H.A. 1962. "The Architecture of Complexity." *Proceedings of the American Philosophical Society.* 106(6) (December 12, 1962): 467-482.

(3) Checkland, P. 1999. *Systems Thinking, Systems Practice*. New York: John Wiley & Sons.

(4) INCOSE. 2012. *Systems Engineering Handbook: A Guide for System Life Cycle Processes and Activities*, version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2.

Discussion

(1) is a general dictionary definition.

(2) is a system science definition, which relates to the tendency of natural systems to form hierarchies and to the stability of hierarchical structures for man-made systems.

(3) Soft systems definition, allowing for a system to be associated with several hierarchical structure, one of the factors leading to multiple stakeholder viewpoints. This is the definition which should be used for problem systems.

(4) defines the man-made hierarchy created within a system. The use of a standard taxonomy defined against the types of technology and use of system elements can be useful as a common language for defining production of support processes. Care must be taken to avoid this leading to a reductionist (glossary) approach. This is the definition which should be used for hard solution systems.

High Reliability Organizations (HROs) (glossary)

> *Organizations that operate continuously under trying conditions and have fewer than their fair share of major accidents.* (Weick and Sutcliffe 2007)

Sources

Weick, K. E. and K.M. Sutcliffe. 2007. *Managing the Unexpected: Resilient Performance in an Age of Uncertainty*, 2nd Edition. San Francisco, CA: Jossey-Bass.

Discussion

Discussion

For a full discussion of the role and importance of system implementation in systems engineering see the System Implementation article.

In-Process Validation (glossary)

The practice of routinely getting user approval to guide each elaboration of the baseline. This technique keeps the user involved and committed to the incremental elaboration of the approach and the incremental verification results. (Mooz, Forsberg, and Cotterman 2003,198)

Sources

Mooz, H., K. Forsberg, H. Cotterman. 2003. *Communicating Project Management.* Hoboken, NJ: John Wiley and Sons.

Discussion

One reason that small software development projects, using Agile development principles, work so well is that the customer is embedded into the team. Agile teams are usually limited to a maximum of 20 people (although there are instances of teams of teams that have hundreds of people involved and working well). The in-process validation concept can effectively capture the customer involvement as a very positive force on large projects.

Inclusion (glossary)

> *The intentional, proactive, and continuing efforts and practices in which all members respect, support, and value others. An inclusive environment provides equitable access to opportunities and resources, empowers everyone to participate equally, and offers respect in words and actions for all.* (ABET 2020)

Source

ABET. 2020. "Diversity, Equity, and Inclusion." Accreditation Board for Engineering and Technology (ABET) website. https://www.abet.org/about-abet/diversity-equity-and-inclusion/Accessed: December 2020.

Increment (glossary)

> *One of a series of planned additions and contributions.* (Mooz, Forsberg, Cotterman 2003, 194)

Sources

Mooz, H., K. Forsberg, H. Cotterman. 2003. *Communicating Project Management.* Hoboken, NJ: John Wiley and Sons.

Discussion

See also incremental.

Incremental (glossary)

To operate using increments. (Mooz, Forsberg, and Cotterman 2003)

Sources

Mooz, H., K. Forsberg, H. Cotterman. 2003. *Communicating Project Management*. Hoboken, NJ: John Wiley and Sons.

Discussion

See also increment.

Industrial Engineering (glossary)

The design, improvement and installation of integrated systems of people, materials, information, equipment and energy. It draws upon specialized knowledge and skill in the mathematical, physical, and social sciences together with the principles and methods of engineering analysis and design, to specify, predict, and evaluate the results to be obtained from such systems (IIE 1992).

Sources

IIE. 1992. *Industrial Engineering Terminology, Revised Edition.* Institute of Industrial Engineers (IIE). Accessed 7 March 2012. Available at http://www.iienet2.org/Details.aspx?id=645.

Discussion

None.

Information and Communications Technologies (ICT) (glossary)

Information and communication technology...include computer hardware (computers, storage devices, printers, and other peripherals); computer software (operating systems, programming tools, utilities, applications, and internal software development); computer services (information technology consulting, computer and network systems integration, Web hosting, data processing services, and other services); and communications services (voice and data communications services) and wired and wireless communications equipment. (World Bank 2012)

Sources

World Bank. 2012. *Information and Communication Technology Expenditure*. Accessed on 11 September 2012. Available at http://search.worldbank.org/data?qterm=ICT&language=EN.

Discussion

None.

Information Category (glossary)

An element of a classification scheme describing the information needs of managers. 'Practical Software Management' defines seven of these:

- *Schedule and progress*
- *Resources and cost*
- *Product size and stability*
- *Product quality*
- *Process performance*
- *Technology effectiveness*
- *Customer satisfaction*

Source(s)

Card, D, and R. McIver. 2003. *Applying PSM to Enterprise Measurement.* Technical Report for US Army TACOM. Herndon, VA, USA: Software Productivity Consortium.

Discussion

None.

Information Need (glossary)

Insight necessary to manage objectives, goals, risks, and problems. (ISO/IEC/IEEE 2007)

Sources

ISO/IEC/IEEE. 2007. *Systems and software engineering - Measurement process.* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), Institute of Electrical and Electronic Engineers (IEEE), ISO/IEC/IEEE 15939:2007, 3.12.

Discussion

None.

Information Technology (glossary)

Resources required to acquire, process, store and disseminate information. (ISO/IEC/IEEE 2008)

Sources

ISO/IEC/IEEE. 2008. *Corporate governance of information technology.* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 38500:2008, 1.6.7.

Discussion

Note from SEVOCAB [1]: includes communication technology (CT) and the composite term information and communication technology (ICT).

Infrastructure (glossary)

> *The assets, systems, and networks, whether physical or virtual, whose incapacitation or destruction would have a debilitating effect on security, national economic security, public health or safety, or any combination thereof.* -- adapted from Department of Homeland Security (DHS 2010, 46)

Sources

DHS. 2010. *Department of Homeland Security Risk Lexicon,* 2010 edition. Accessed on 11 September 2012. Available at http://www.dhs.gov/xlibrary/assets/dhs-risk-lexicon-2010.pdf.

Discussion

This term is discussed in a resilience context. That is also the context in which the *DHS Risk Lexicon* was written.

Input (glossary)

When used as a noun:

> (1) *Data received from an external source.* (ISO/IEC 2009)
>
> (2) *Pertaining to a device, process, or channel involved in receiving data from an external source.* (ISO/IEC 2009)
>
> (3) *In an IDEF0 model, that which is transformed by a function into output.* (ISO/IEC 2009)
>
> (4) *Any item, whether internal or external to the project that is required by a process before that process proceeds.* (ISO/IEC 2009)
>
> (5) *Data entered into an information processing system or any of its parts for storage or processing.* (ISO/IEC 2009)

When used as a verb:

> (6) *The process of entering data into an information processing system or any of its parts for storage or processing.* (ISO/IEC 2009)
>
> (7) *To receive data from an external source;* (ISO/IEC 2009)
>
> (8) *To provide data from an external source.* (ISO/IEC 2009)

Source

(1) - (8) ISO/IEC. 2009. *Systems and Software Engineering Vocabulary (SEVocab)* - ISO/IEC 24765. in International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) [database online]. Discussion

None.

Input-Output Flow (glossary)

> *An input or an output, or a trigger of a function (used for input-output flow, control flow). An Input-Output Flow can be made of material and/or energy, and/or information.* (Faisandier 2012)

Source

Faisandier, A. 2012. *Systems Opportunities and Requirements*. Belberaud, France: Sinergy'Com.

Discussion

See Logical Architecture Model Development article.

Installation (glossary)

> *Period of time in the system life cycle during which a product is integrated into its operational environment and tested in this environment to ensure that it performs as required.* (Adapted from (ISO/IEC 2009))

Source

ISO/IEC. 2009. *Systems and Software Engineering Vocabulary (SEVocab)* - ISO/IEC 24765. in International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) [database online]. Geneva, Switzerland, 2009 [cited December 21, 2009]. Available from http:// pascal. computer. org/ sev_display/ index. action.

Discussion

None.

Integrated Product Team (IPT) (glossary)

(1) *An interdisciplinary team assigned to an element of the system breakdown structure* (Created for SEBoK).

(2) *An interdisciplinary team* (Created for SEBoK).

Sources

This definition was developed for the SEBoK.

Discussion

The primary definition is adapted from Browning (2009) and corresponds to the traditional meaning of "Integrated Product Team". The second definition is not found in any reference but corresponds to the meaning that has evolved in many segments of industry. In industry the term "functional IPT" is also used to designate teams that are not assigned to an element of the system structural breakdown structure but rather represent disciplines that cross system element boundaries, such as reliability.

Works Cited

Browning, T.R. 2009. "Using the Design Structure Matrix to Design Program Organizations." In *Handbook of Systems Engineering and Management*, edited by A.P. Sage and W.B. Rouse. Hoboken, NJ: John Wiley & Sons, p. 1415-1416.

Integration (glossary)

A process that combines system elements to form complete or partial system configurations in order to create a product specified in the system requirements. (ISO/IEEE 2008)

Source

ISO/IEEE. 2008. *Systems and Software Engineering - Software Life Cycle Processes*. Geneva, Switzerland: International Organization for Standards (ISO)/Institute of Electrical & Electronics Engineers (IEEE) Computer Society, ISO/IEEE 12207:2008(E).

Discussion

For a full discussion of the role and importance of integration in systems engineering see the System Integration article.

Integrity (glossary)

> *[1] the state of being whole and undivided. (Oxford Online Dictionary 2016)*
>
> [2] Degree to which a system or component prevents unauthorized access to, or modification of, computer programs or data. *(ISO/IEC 2011)*

Sources

[1] Oxford On-line Dictionary (2016)

[2]ISO/IEC. 2011. *Systems and Software Engineering - Systems and Software Quality Requirements and Evaluation (SQuaRE) - Systems and Software Quality Models.* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC). ISO/IEC 25010:2011.

Discussion

In a resilience context integrity is an attribute of a system before, during and after an encounter with a threat.

Inter-Node Interaction (glossary)

> *The combination of communications, cooperation, and collaboration among the different nodes or elements of a system to act together to solve both local and strategic problems.* Adapted from (Woods 2006)

According to Jackson and Ferris (2013) internode interaction is the primary principle of the integrity characteristic.

Sources

Woods, D.D. 2006. "Essential Characteristics of Resilience." In *Resilience Engineering: Concepts and Precepts,* edited by E. Hollnagel, Woods, David D., and Leveson, Nancy. Aldershot, UK: Ashgate Publlishing Limited.

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Discussion

This is essentially the same concept discussed by Woods (2006) in a resilience context except that the term used by Woods is "cross-scale interaction."

Interface (glossary)

1. A shared boundary between two functional units, defined by various characteristics pertaining to the functions, physical signal exchanges, and other characteristics. (ISO/IEC 1993)

2. A hardware or software component that connects two or more other components for the purpose of passing information from one to the other. (ISO/IEC 1993)

3. To connect two or more components for the purpose of passing information from one to the other. (ISO/IEC/IEEE 2009)

Discussion

None.

Internal Coordinate Reference System (glossary)

A coordinate reference system having a datum specified with reference to the object itself.

Sources

ISO TC211. "Internal coordinate reference system." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 1004. Available at: https://isotc211.geolexica.org/concepts/1004/.

Discussion

None.

Internode Interaction (glossary)

a system resilience principle that states that every node, or element, of a system should be capable of communicating, cooperating, and collaborating with every other node. Jackson and Ferris (2013)

Source

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Discussion

In a resilience context the internode interaction principle supports the integrity attribute.

Interoperability (glossary)

(1) *Degree to which two or more systems, products or components can exchange information and use the information that has been exchanged.* (ISO/IEC 2009)

(2) *The ability for two or more ORBs to cooperate to deliver requests to the proper object.* (ISO/IEC 2003)

(3) *The capability to communicate, execute programs, and transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units.* (ISO/IEC 1993)

Source

(1) ISO/IEC/IEEE. 2009. Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab). Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2009.

(2) ISO/IEC. 2003. *Information technology -- Open Distributed Processing -- Part 2: General Inter-ORB Protocol (GIOP)/Internet Inter-ORB Protocol (IIOP), 3.2.19*. (3) ISO/IEC. 1993. Information technology--Vocabulary--Part 1: Fundamental terms. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 2382-1:1993.

Discussion

None.

Issue (glossary)

(1) *An area of concern that may impact the achievement of program/organizational objectives – a problem (existing), a risk (future uncertainty), or lack of information (existing).* (PSM 2010)

(2) *A concern that has a probability of occurrence equal to one, a consequence of occurrence greater than zero, and a time-frame in the future. An issue will occur and have a negative impact to the project, but it will not immediately occur.* (Conrow 2008)

Source

(1) PSM. 2010. *Practical Software and Systems Measurement: A Foundation for Objective Project Management*, version 4.0. Bethesda, MD, USA: Practical Software and Systems Measurement.

(2) Conrow, E. 2008. "Risk Analysis for Space Systems." Space Systems Engineering and Risk Management Symposium, 27-29 February, 2008, Los Angeles, CA, USA.

Discussion

Definition (2) defines issue in terms of probablity of occurrence, consequence of occurrence, and time-frame; all of which are measurable.

Iteration (glossary)

The action or a process of iterating or repeating an action or process; a procedure in which repetition of a sequence of operations yields results successively closer to a desired result. (Oxford English Dictionary)

Sources

Oxford English Dictionary. s.v. "Iteration."

Discussion

This dictionary definition captures the essential idea of repeating an action in order to get closer to the answer we need.

Iteration is used as a generic term for successive application of a systems approach to the same problem situation, learning from each application, in order to progress towards greater stakeholder satisfaction.

K

Knowledge (glossary)

1. *acquaintance with facts, truths, or principles, as from study or investigation; general erudition: knowledge of many things.*
2. *acquaintance or familiarity gained by sight, experience, or report: a knowledge of human nature.*
3. *the fact or state of knowing; the perception of fact or truth; clear and certain mental apprehension.*

Source

Dictionary.com. 2012 "Knowledge." Available at http://dictionary.reference.com/browse/knowledge [1].

Discussion

None.

Leader (glossary)

A leader is one or more people who selects, equips, trains, and influences one or more follower(s) who have diverse gifts, abilities, and skills and focuses the follower(s) to the organization's mission and objectives causing the follower(s) to willingly and enthusiastically expend spiritual, emotional, and physical energy in a concerted coordinated effort to achieve the organizational mission and objectives.

Sources

Winston, B. E. and K. Patterson. 2006. "An Integrative Definition of Leadership." *International Journal of Leadership Studies,*: 1(2):6-66.

Discussion

Many definitions of leader exist such a the simple Merriam-Webster definition of "a person who leads as a guide, conductor." However, the definition provided above gives a more complete and elucidative definition that is more useful in the context of leaders of teams in organizations.

Lean Systems Engineering (LSE) (glossary)

(1) The application of lean principles, practices, and tools to SE to enhance the delivery of value to the system's stakeholders. (Oppenheim, Murman, and Secor 2011)

(2) Lean Systems Engineering (LSE) is the area of synergy between lean thinking and SE, with the goal to deliver the best life-cycle value for technically complex systems with minimal waste; under the lean SE philosophy, mission assurance is non-negotiable, and any task that is legitimately required for success must be included, but it should be well-planned and executed with minimal waste. (INCOSE 2012)

Sources

Discussion

None.

Lean Value Stream Mapping (glossary)

> *Map all end-to-end linked tasks, control/decision nodes, and the interconnecting flows necessary to realize customer value. During the mapping process, eliminate all non-value added activities, minimize all necessary non-value activities, and enable the remaining activities to flow without rework, backflow, or stopping.* (Oppenheim 2011)

Sources

Oppenheim, B.W., 2011. *Lean for Systems Engineering With Lean Enablers for Systems Engineering*. Hoboken, NJ, USA: J. Wiley & Sons, Pg 17, 20.

Discussion

None.

Legacy System (glossary)

> (1) *A system that has been in operation for a long time, and whose functions are too essential to be disrupted by upgrading or integration with another system.* (Arbutus Software 2012)
>
> (2) *A legacy system is an old method, technology, computer system, or application program that continues to be used, typically because it still functions for the users' needs, even though newer technology or more efficient methods of performing a task are now available. A legacy system may include procedures or terminology which are no longer relevant in the current context, and may hinder or confuse understanding of the methods or technologies used.* (Wikipedia Contributors 2012)

Source

(1) Arbutus Software. "Legacy Systems." Accessed September 12, 2012. Available at: http://www.arbutussoftware.com/data-source/legacy-systems/.

Discussion

Seacord, R.C., D. Plakosh, and G.A. Lewis. 2003. *Modernizing Legacy Systems: Software Technologies, Engineering Processes, and Business Practices*. Boston, MA, USA: Pearson Education.

discusses the difficulties of updating or modifying a legacy system's software

Leverage (glossary)

> *Leverage (of a solution) is the degree to which it satisfies the following two criteria (which are, in general, conflicting): (a) number of problem situations to which it applies, and (b) extent to which it provides the complete solution needed for the specific problem situations to which it applies. Leverage is the product of these two criteria.* (Hybertson 2009).

Sources

Hybertson, D. 2009. *Model-Oriented Systems Engineering Science: A Unifying Framework for Traditional and Complex Systems*. Auerbach/CRC Press, Boca Raton, FL.

Discussion

Leverage describes the balance in system thinking between making specialised system to solve a single problem well vs making generalist system which can be applied to a wide range of problems (see Principles of Systems Thinking).

Life Cycle (glossary)

> *(1) The organized collection of activities, relationships and contracts which apply to a system-of-interest during its life.* (Pyster 2009, 73)
>
> *(2) The evolution of a system, product, service, project or other human-made entity from conception through retirement.* (ISO/IEC/IEEE 2015)
>
> *(3) Development (life) cycles start with user needs and end with system decommissioning and disposal. Project cycles contain three aspects: business, budget, and technical.* (Mooz, Forsberg, Cotterman 2003, 259)

Source

Discussion

None.

Life Cycle Management (glossary)

> *The end-to-end management of the life cycle.* (Created for SEBoK)

Sources

This definition was created for the SEBoK.

Discussion

See also Life Cycle (glossary).

Life Cycle Model (glossary)

> *A framework of processes and activities concerned with the Life Cycle (glossary) that may be organized into stages, which also acts as a common reference for communication and understanding* (ISO/IEC 15288)

Sources

ISO/IEC. 2008. *Systems and Software Engineering -- System Life Cycle Processes.* Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions. ISO/IEC/IEEE 15288:2008.

Discussion

The life cycle models most commonly used in systems engineering are described in the Life Cycle Models article.

Life Cycle Process (glossary)

> (1) *A process is a set of interrelated or interacting activities which transforms inputs into outputs* (ISO/IEC 2008).
>
> (2) *Life cycle: evolution of a system, product, service, project or other human-made entity from conception through retirement.* (ISO/IEC 2008)

Sources

(1) and (2) ISO/IEC. 2008. *Systems and Software Engineering -- System Life Cycle Processes*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions. ISO/IEC/IEEE 15288:2008

Discussion

A life cycle process is a process that is applied during the application of the life cycle model. ISO 15288 (2008) lists and describes 25 life cycle processes for systems and software engineering. These are aggregated into four groups: agreement processes, technical processes, organizational project-enabling processes, and project processes.

Localized Capacity (glossary)

> *A design principle that allows a system to degrade gradually upon the encounter with a threat. It assumes that the capability of a system is concentrated in local nodes so that no more than one node fails at a time.* -- adapted from (Woods 2006)

Sources

Woods, D.D. 2006. "Essential Characteristics of Resilience." In *Resilience Engineering: Concepts and Precepts*, edited by E. Hollnagel, Woods, D.D., and N. Leveson. Aldershot, UK: Ashgate Publlishing Limited.

Discussion

This is a key design principle in the context of resilience to achieve the attribute of tolerance.

Location (glossary)

> *Insert definition here.* (Reference YEAR)

Source

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Location-Based Service (LBS) (glossary)

> *A service whose return or other property is dependent on the location of the client requesting the service or of some other thing, object or person.*

Source

ISO TC211. "Location based service." In: ISO TC211 Multilingual Glossary. Version from 2020-06-02. Concept ID: 278. Available at: https://isotc211.geolexica.org/concepts/278/ [1]

Discussion

None.

References

[1] https://isotc211.geolexica.org/concepts/278/

Logical Architecture (glossary)

> *The logical architecture of a system is composed of a set of related technical concepts and principles that support the logical operation of the system. It includes a functional architecture, a behavioral architecture, and a temporal architecture.* (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

The term "logical architecture" is used in ISO/IEC/IEEE 15288:2008 without normative reference.

For a full discussion of the role and importance of logical architecture in systems engineering see the Logical Architecture Model Development article.

Logistics (glossary)

> *The science of planning and implementing the acquisition and use of the resources necessary to sustain the operation of a system.* (Cooke 1993)

Source

Cooke, W. 1993. "Integrated Logistics." *HUM - the Government Computer Magazine*. December 1993.

Discussion

None.

Loose Coupling (glossary)

> *The relationship among element in a system in which events in various elements can occur independently* -- adapted from (Perrow 1999, 8)

Sources

Perrow, C. 1999. *Normal Accidents.* Princeton, NJ: Princeton University Press.

Discussion

Perrow is an authority on accidents in a system and the system characteristics that may cause them. This term is used in a reilience context.

Loss-Driven Systems Engineering (glossary)

An overarching system engineering process that addresses quality characteristics concerned with potential losses (such as resilience, safety, and security) in a holistic manner.

Sources

SEBoK original.

Discussion

Loss-driven systems engineering (LDSE) is an area of systems engineering that holistically addresses the quality characteristics concerned with loss (such as resilience, safety, and security).

M

Maintainability (glossary)

(1) *Maintainability is defined as the probability that a system or system element can be repaired in a defined environment with defined resources within a specified period of time. Increased maintainability implies shorter repair times.* (Created for SEBoK)

(2) *The American Society for Quality uses this definition. "Maintainability: The probability that a given maintenance action for an item under given usage conditions can be performed within a stated time interval when the maintenance is performed under stated conditions using stated procedures and resources."* (ASQ 2011) The definition above simplifies the ASQ definition.

Sources

(1) This definition was developed for the SEBoK.

(2) American Society for Quality. 2011. "Glossary: Maintainability." Accessed on 11 September 2012. Available at http://asq.org/glossary/m.html.

Discussion

None.

Maintenance (glossary)

The process of modifying a system or component after delivery to correct faults, improve performance or other attributes, or adapt to a changed environment.

Source

ISO/IEC/IEEE. 2010. *Systems and Software Engineering -- Vocabulary (SEVocab)* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronic Engineers (IEEE) 2009 ISO/IEC/IEEE 24765:2010 [database online]. Mean Sea Level(glossary)

(1)*The average level of the surface of the sea over all stages of tide and seasonal variations.*

(2)*The average height of the surface of the sea at a tide station for all stages of the tide over a 19-year period, usually determined from hourly height readings measured from a fixed predetermined reference level.*

Note to definition (1): Mean sea level in a local context normally means mean sea level for the region calculated from observations at one or more points over a given period of time. Mean sea level in a global context differs from a global geoid by not more than 2 m.

Sources

Measurable Concept (glossary)

Abstract relationship between attributes of entities and information needs. (ISO/IEC/IEEE 2007)

Sources

ISO/IEC/IEEE. 2007. *Systems and software engineering - Measurement process*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC/IEEE 15939:2007. 3.14

Discussion

None.

Measure (glossary)

When used as a noun:

> (1) *A variable to which a value is assigned as the result of measurement. [The plural form "measures" is used to refer collectively to base measures, derived measures, and indicators.]* (PSM May 7, 2010; ISO/IEC/IEEE 2007)

When used as a verb:

> (2) *To ascertain a quantitative or qualitative value for an entity based on a standard of comparison;* (PSM 2010)
>
> (3) *To make a measurement.* (ISO/IEC 14598-1:1999).

Source

Meta-model (glossary)

A model about a model.

Sources

Cited in Haskins, C. 2008. "Systems engineering analyzed, synthesized, and applied to sustainable industrial park development" (PhD diss., Norwegian University of Science and Technology, 2008).

Discussion

There are also alternative definitions of "meta-model" fashioned for specific applications of its use that have been defined in standards below:

> *(1) A logical information model that specifies the modeling elements used within another (or the same) modeling notation.* (IEEE 1175.1-2002 (R2007) IEEE Guide for CASE Tool Interconnections-Classification and Description, 3.8)
>
> *(2) A metamodel Vm for a subset of IDEFobject is a view of the constructs in the subset that is expressed using those constructs such that there exists a valid instance of Vm that is a description of Vm itself.* (IEEE 1320.2-1998 (R2004) IEEE Standard for Conceptual Modeling Language Syntax and Semantics for IDEF1X97 (IDEFobject), 3.1.111)
>
> *(3) A model containing detailed definitions of the meta-entities, meta-relationships and meta-attributes whose instances appear in the model section of a CDIF transfer.* (ISO/IEC 15474-1:2002 Information technology -- CDIF framework -- Part 1: Overview, 4.2)
>
> *(4) Specification of the concepts, relationships and rules that are used to define a methodology.* (ISO/IEC 24744:2007 Software Engineering--Metamodel for Development Methodologies, 3.4)
>
> *(5) Model defining the concepts and their relations for some modeling notation.* (ISO/IEC 15909-2:2011 Software and system engineering -- High-level Petri nets -- Part 2: Transfer format, 4.1.6)

Mission (glossary)

The mission of a system is the top-level function of the system; the one that synthesizes all transformation of all inputs and solicitations into outputs and reactions. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

For a full discussion of the role and importance of a clear understanding of mission needs in systems engineering see the Business or Mission Analysis article.

Mission Analysis (glossary)

> *Examination and definition of the primary and secondary purposes of a system.* - modified from (Blanchard and Fabryky 2011)

Sources

Modified from:

Blanchard, B. S., and W. J. Fabrycky. 2011. *Systems Engineering and Analysis*, 5th ed. Prentice-Hall International series in Industrial and Systems Engineering. Englewood Cliffs, NJ, USA: Prentice-Hall.

Discussion

Though Blanchard and Fabrycky (2011) do not define "mission analysis", their discussion of "mission definition" is relevant to mission analysis. Effectively, mission analysis is a set of activities designed to help answer the questions (Blanchard and Fabryky 2011):

- What is the system to accomplish? and
- How will the system accomplish its objectives?

The purpose of MA is to understand a problem or opportunity, analyze the solution space, and initiate the life cycle of a potential solution that could answer the problem or take advantage of an opportunity.

Mission Engineering (glossary)

> *Mission Engineering describes the application of systems engineering to the planning, analysis, and designing of missions, where the mission is the system of interest.* (SEBoK Original)

Source

SEBoK original.

Discussion

None.

Model (glossary)

(1) *A physical, mathematical, or otherwise logical representation of a system, entity, phenomenon, or process.* (DoD 1998)

(2) *A representation of one or more concepts that may be realized in the physical world.* (Friedenthal, Moore, Steiner 2009)

(3) *A simplified representation of a system at some particular point in time or space intended to promote understanding of the real system.* (Bellinger 2004)

(4) *An abstraction of a system, aimed at understanding, communicating, explaining, or designing aspects of interest of that system* (Dori 2002)

(5) *A selective representation of some system whose form and content are chosen based on a specific set of concerns. The model is related to the system by an explicit or implicit mapping.* (Object Management Group 2010)

Source

Discussion

None.

Modeling Language (glossary)

A language in which a model is expressed. It includes syntax, rules and its semantics. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

See the knowledge area Representing Systems with Models for discussions on modeling systems.

Modeling Tool (glossary)

A tool such as a software application that is used to develop models. (Friedenthal 2009)

Sources

Friedenthal, S., A. Moore, R. Steiner, and M. Kaufman. 2012. *A Practical Guide to SysML: The Systems Modeling Language*, 2nd Edition. Needham, MA, USA: OMG Press.

Discussion

None.

Modularity (glossary)

(1) Degree to which a system or computer program is composed of discrete components such that a change to one component has minimal impact on other components. (ISO/IEC 2011)

(2) Software attributes that provide a structure of highly independent components. *(ISO/IEC/IEEE 2010)*

(3) In a resilience context modularity is a system resilience principle that states that the functionality of a system should be distributed through various nodes of that system so that if a single node is damaged or destroyed, the remaining nodes will continue to function. Jackson (2016)Modularity is a component principle in the tolerance attribute grouping. Jackson (2016)

Neutral State (glossary)

> *A resilience design principle that states that a system should be put into neutral if possible following a disruption.* (Madni and Jackson 2009)

According to Jackson and Ferris (2013) neutral state is a component principle in the tolerance attribute grouping.

Sources

Madni, A. and S. Jackson. 2009. "Towards a conceptual framework for resilience engineering." IEEE *Systems Journal* 3(2):181-191.

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Discussion

This is a key resilience design principle.

Node (glossary)

> *An element of a system.* (Created for SEBoK)

Sources

This definition was created for the SEBoK.

Discussion

There are also alternative definitions of "node" fashioned for specific applications of its use that have been defined in standards below:

> *(1) In a diagram, a point, circle, or other geometric figure used to represent a state, event, or other item of interest.* (ISO/IEC/IEEE 24765:2010 Systems and software engineering--Vocabulary)
>
> *(2) Configuration of engineering objects forming a single unit for the purpose of location in space, and which embodies a set of processing, storage and communication functions.* (ISO/IEC 10746-3:2009 Information technology -- Open Distributed Processing -- Reference Model: Architecture, 8.1.7)
>
> *(3) Modeled function located within the hierarchical graph structure of an IDEF0 model by its designated node number.* (IEEE 1320.1-1998 (R2004) IEEE Standard for Functional Modeling Language - Syntax and Semantics for IDEF0, 2.1.80)
>
> *(4) One of the defining points of a schedule network; a junction point joined to some or all of the other dependency lines.* (PMI 2008)
>
> *(5) Vertex of a net graph, i.e., a place or a transition.* (ISO/IEC 15909-1:2004 Software and system engineering -- High-level Petri nets -- Part 1: Concepts, definitions and graphical notation, 2.1.16.2)

Open System (glossary)

A system which exchanges inputs and outputs with its environment. (von Bertalanffy 1968)

Source

von Bertalanffy, L. 1968. *General system theory: Foundations, development, applications,* Revised ed. New York, NY: Braziller.

Discussion

Open system theory considers an organism as a complex entity composed of many parts with an overall integrity, co-existing in an environment. In an open system the organisms structure is maintained, or adapts, through a continual exchange of energy and information with its environment.

Operational (glossary)

Of or relating to the routine functioning and activities of a business or an organization. (American Heritage Dictionary 2009)

Sources

American Heritage Dictionary, v2.1.3. 2009. "Operational."

Discussion

None.

Operational Capability (glossary)

The ability of a system to perform in the intended operational environment, particularly with respect to meeting the requirements of its stakeholders. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

See the article Enterprise Systems Engineering Background for discussions on operational capability of an enterprise.

Operational Concept (glossary)

Operational Concept: verbal and graphic statement of an organization's assumptions or intent in regard to an operation or series of operations of a system or a related set of systems. (ANSI/AIAA G-043-199)

Source

ISO/IEC/IEEE. 2011. Systems and software engineering - Requirements engineering. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission/ Institute of Electrical and Electronics Engineers (IEEE), (IEC), ISO/IEC/IEEE 29148.

Discussion

The operational concept is designed to give an overall picture of the operations using one or more specific systems, or set of related systems, in the organization's operational environment from the users' and operators' perspective. See also concept of operations.

Operational Environment (glossary)

The environment in which systems are deployed. The problem or opportunity in response to which the system has been developed, exists in this environment. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

The operational environment is a significant factor in defining the needed system capabilities, desired stakeholder outcomes and benefits, and constraints.

Operational Mode (glossary)

An operational situation/configuration of a system characterized by its active functions. Inside an operational mode the system can perform specific operational scenarios, and so activate the corresponding functions. (same as state) (Faisandier 2012)

Source(s)

Faisandier, A. 2012. *Systems Architecture and Design*. Belberaud, France: Sinergy'Com.

Discussion

None.

Operational Scenario (glossary)

(1) Description of an imagined sequence of events that includes the interaction of the product or service with its environment and users, as well as interaction among its product or service components. (ISO/IEC 2011)

(2) A set of actions or functions representing the dynamic of exchanges between the functions allowing the system to achieve a mission or a service. (Created for SEBoK)

(3) Stories which describe the expected utilization of the future system in terms of actions. (Created for SEBoK)

Source

(1) ISO/IEC/IEEE. 2011. Systems and software engineering - Requirements engineering. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission/ Institute of Electrical and Electronics Engineers (IEEE), (IEC), ISO/IEC/IEEE 29148.

(2) and (3) These definitions were developed for the SEBoK.

Discussion

Operational scenarios are used to evaluate the requirements and design of the system and to verify and validate the system.

Operations Research (glossary)

'Operations Research (OR) considers the use of technology by an organization. It is based on mathematical modeling and statistical analysis to optimize decisions on the deployment of the resources under an organizations control. It arises from military planning techniques developed during World War 2.

Operations Research and Management Science *(ORMS) was formalized in 1950 by* ***Ackoff*** *and* ***Churchman*** *applying the ideas and techniques of OR to organizations and organizational decisions .* (Churchman et al, 1950)

Source

Churchman, C.W., R.L. Ackoff, and E.L. Arnoff. 1950. *Introduction to Operations Research*. New York, NY, USA: Wiley.

Discussion

Operations research (OR) and *operations research and management science* (ORMS) are used interchangeably in many sources. The term operations analysis is used in the UK, especially in defense.

Opportunity (glossary)

(1) *an appropriate or favorable time or occasion; a situation or condition favorable for attainment of a goal; a good position, chance, or prospect, as for advancement or success.* (Dictionary.com 2012)

(2) *an outcome better than expected; a less negative outcome; a positive outcome.* (Conrow 2003)

Sources

(1) Dictionary.com. 2012. "Opportunity." Online dictionary.

(2) Conrow, E. 2003. *Effective Risk Management: Some Keys to Success.* 2nd ed. Reston, VA, USA: American Institute of Aeronautics and Astronautics (AIAA).

Discussion

(1) is a dictionary definition which associates oppourtunity with a situation in which a system intervention might lead to additional stakeholder benefit. This definition applies to the front end of the Systems Approach, and is used to broaden our view of Problem Situations.

2) Comes from Risk Management which uses opportunity as the likelihood and impact of a beneficial outcome. In risk management a variety of different classes of outcomes can be termed an opportunity, which may not be uniquely specified. Risk can be defined in terms of specific bounds on probability ($0 < P < 1$), consequence (> 0), and time-frame (future), as can issue [$P = 1$, $C > 0$, and time-frame (future)] and problem [$P = 1$, $C > 0$, and time-frame (present)]. However, similar definitions are unavailable for opportunity because of the inability to uniquely specify whether the case of $P = 1$ is included or excluded, consequence (can be positive or negative) and time-frame (present, future, with no analog to issue and problem).

Works Cited

Organization (glossary)

> *A group of people and facilities with an arrangement of responsibilities, authorities and relationships.* (INCOSE 2011)

Sources

INCOSE. 2012. *Systems Engineering Handbook*, version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE). INCOSE-TP-2003-002-03.2.2. p. 361.

Discussion

The INCOSE *Systems Engineering Handbook* is an established systems engineering source. The current INCOSE *Systems Engineering Handbook* version 3.2.1 has this definition as, “Person or a group of people and facilities with an arrangement of responsibilities, authorities and relationships.” The earlier version 3 had, “A group of people and facilities with an arrangement of responsibilities, authorities and relationships.” Other definitions of "organization" researched all relate to a group of people, not a single person, so the current version 3.2.1 is not cited. The version 3 definition is used since it is succinct, clear, and consistent with other sources.

Organizational (glossary)

> *Of or pertaining to an organization*.

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Outcome (glossary)

a) Process outcomes represent measurable and observable results or change of state achieved by executing a process. (Created for SEBoK)

b) Significant change of state or the meeting of specified constraints. e.g., requirements or goals. (ISO/IEC/IEEE DIS)

c) End result or consequence of a process or project. (PMI, 2021)

Source

a) This definition was developed for the SEBoK.

b) ISO/IEC/IEEE. DIS. *Systems and software engineering — Vocabulary*. Geneva, Switzerland: International Organization for Standardization (ISO), International Electrotechnical Commission (IEC), and Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765 DIS (Draft International Standard).

c) PMI. 2021. *A Guide to the Project Management Body of Knowledge, 7th Edition.* Project Management Institute.

Discussion

This definition was developed to support Process Description in the SEBoK.

Output (glossary)

When used as a noun:

(1) *Data transmitted to an external destination.* (ISO/IEC 2009, 1)

(2) *Pertaining to a device, process, or channel involved in transmitting data to an external destination.* (ISO/IEC 2009, 1)

(3) *Pertaining to data transmitted to an external destination.* (ISO/IEC 2009, 1)

When used as a verb:

(4) *To transmit data to an external destination.* (ISO/IEC 2009, 1)

Source

Discussion

None.

P

Paradigm (glossary)

A view of the world that may or may not conflict with accepted scientific principles. -- adapted from (Vaughn 1997, 196)

Sources

Vaughn, Diane 1997. *The Challenger Launch Decision: Risky Technology, Culture, and Deviance at NASA*. Chicago: University of Chicago Press. Original edition, 1996.

Discussion

Although the standard definition of *paradigm* is simply *example*, the word has come to mean in Vaughn's sense a way of thinking that may be positive or negative with respect to the Culture involved in the development and operation of a system, such as the Challenger. In a positive sense *paradigm* can mean the way of thinking about the systems engineering methodology itself.

Pattern (glossary)

(1) An expression of an observed regularity. (Alexander 1979)

(2) A representation of similarities in a set or class of problems, solutions, or systems. (Alexander 1979)

(3) Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice. (Alexander 1979)

Sources

(1) - (3) Alexander, C. 1979. *The Timeless Way of Building*. New York, NY, USA: Oxford University Press.

Discussion

A full discussion of patterns and how they relate to systems thinking can be found in Patterns of Systems Thinking.

Personnel (glossary)

An individual expected to perform duties on behalf of the organization, including officers, employees and contractors. (ISO/IEC 2006)

Sources

ISO/IEC. 2006. *Information technology -- Software asset management -- Part 1: Process.* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC). ISO/IEC 19770-1:2006.

Discussion

None.

Physical Architecture (glossary)

(1) *A physical architecture is an arrangement of physical elements (system elements and physical interfaces) which provides the design solution for a product, service, or enterprise, and is intended to satisfy logical architecture elements and system requirements. It is implementable through technologies.* (ISO/IEC 2010)

(2) *An arrangement of physical elements which provides the design solution for a consumer product or life-cycle process intended to satisfy the requirements of the functional architecture and the requirement baseline.* (ISO/IEC 2007)

Source

(1) Adapted from ISO/IEC. 2010. *Systems and Software Engineering, Part 1: Guide for Life Cycle Management*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 24748-1:2010.

(2) ISO/IEC. 2007. *Systems and Software Engineering -- Recommended Practice for Architectural Description of Software-Intensive Systems*. Geneva, Switzerland: International Organization for Standards (ISO)/International Electrotechnical Commission (IEC), ISO/IEC FDIS 42010:2007.

Discussion

Definition (1) comes from the terms "design architecture" provided in ISO/IEC/IEEE 24748 - 4. It is adapted here to be consistent current terminology, in particular with logical architecture.

Definition (2) comes from ISO/IEC/IEEE 42010:2007 that is replaced by version 2011 in which this definition has been withdrawn.

For a full discussion of the role and importance of physical architecture in systems engineering see the Physical Architecture Model Development article.

Physical Interface (glossary)

> *A physical interface is a system element that binds physically two system elements.* (Faisandier 2012)

Sources

Faisandier, A. 2012. *Systems Architecture and Design*. Belberaud, France: Sinergy'Com.

Discussion

None.

Physical Model (glossary)

> *A model made of tangible components.* (Sage and Rouse 2009)

Sources

Sage, A. and W. Rouse. 2009. *Handbook of Systems Engineering and Management.* Hobken, NJ, USA: J. Wiley and Sons.

Discussion

None.

Physical redundancy (glossary)

> a system resilience principle that states that the system should possess two or more independent and identical legs to perform critical tasks. Jackson (2016)

Source

Jackson, Scott. 2016. "Principles for Resilient Design - A Guide for Understanding and Implementation." In IRGC Rresource Guide on Resilience, edited by I. Linkov. University of Lausanne, Switzerland: International Risk Governance Council (IRGC).

Discussion

Also called design redundancy by Leveson (1995)

Plan (glossary)

> *Information item that presents a systematic course of action for achieving a declared purpose, including when, how, and by whom specific activities are to be performed.* (ISO/IEC/IEEE 2011)

Source

ISO/IEC/IEEE. 2011. "Section 5.16," in *Systems and software engineering - Content of the life-cycle information products (documentation).* Geneva, Switzerland: International Organisation for Standardisation (ISO) / International Electrotechnical Commissions (IEC) / Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 15289:2011.

Discussion

None.

Pluralist (glossary)

> *A problem situation involving participants in which "although their basic interests are compatible, they do not share the same values and beliefs. Space needs to be made available within which debate, disagreement, even conifct, can take place. If this is done, and all feel they have been involved in decision-making, then accommodations and compromises can be found. Participants will come to agree, at least temporarily, on productive ways forward and will act accordingly."* (Jackson 2003, 19)

Sources

Jackson, M. 2003. *Systems Thinking: Creating Holisms for Managers.* Chichester, UK: Wiley.

Discussion

None.

Portfolio (glossary)

> *A collection of projects or programs and other work that are grouped together to facilitate effective management of that work to meet strategic business objectives. The projects or programs of the portfolio may not necessarily be interdependent or directly related.* (PMI 2008)

Sources

PMI. 2008. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide),* 4th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

Discussion

See also project and program.

Portfolio Management (glossary)

> *The centralized organization and administration of one or more collections of projects, which includes identifying, prioritizing, authorizing, managing, and controlling projects, programs, and other related work, to achieve specific strategic business objectives.* (PMI 2008)

Source

PMI. 2008. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide),* 4th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

Discussion

None.

Portrayal (glossary)

The presentation of information to humans.

Sources

ISO TC211. "Portrayal." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 342. Available at: https://isotc211.geolexica.org/concepts/342/.

Discussion

None.

Positional accuracy (glossary)

Insert definition here. (Reference YEAR)

Source

Insert full source info (Author Last, FI. YEAR. TITLE. Publisher. URL)

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Postal address type (glossary)

Insert definition here. (Reference YEAR)

Source

Insert full source info (Author Last, FI. YEAR. TITLE. Publisher. URL)

Annotation

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Postmodernist (glossary)

> *Postmodernists believe that we live in a world of multiple truths that give rise to incommensurable interpretations of reality and think that we should promote di¡erence rather than seek to subsume it in the quest for agreement and consensus.* (Jackson 2003)

Sources

Jackson, M. 2003. *Systems Thinking: Creating Holisms for Managers*. Chichester, UK: Wiley.

Discussion

Postmodernism is defined here as it is used to describe an approach to systems in which all notions of problem or solution are rejected in favor of creating an environment in which people can be innovative and creative in response to changing situations.

Praxis (glossary)

> *(1) Praxis is the process of translating an idea into action* (WordNet).
>
> *(2) In praxis there can be no prior knowledge of the right means by which we realize the end in a particular situation. For the end itself is only specified in deliberating about the means appropriate to a particular situation." (Bernstein 1983).*

Sources

(1) WordNet 3.1. Accessed on 1 August 2012. Available at http://wordnetweb.princeton.edu.

(2) Bernstein, R.J. (1983). Beyond Objectivism and Relativism: Science, hermeneutics and praxis. Oxford: Basil Blackwell.

Discussion

The term Praxis has meaning in politic, education, philosophy and spiritualism. It appears in the writing of Aristotle and Marx, both of whom relate it to the translation of philosophical ideas into real world action. Both also associate this in their different ways with moral notions of freedom of action and doing good by taking the right actions.

Praxis is also associated with a way of thinking in which practical considerations drive the development of theoretic approaches and visa versa (see 2 above).

Members of the Systems Science community have adopted the term to characterize work to develop an integrated approach to practice, which provides a framework for the use of appropriate elements of available theory as needed and helps to drive the development of that theory to resolve practical concerns as they arise.

Preliminary Design Review (PDR) (glossary)

> *A review conducted to evaluate the progress, technical adequacy, and risk resolution of the selected design approach for one or more configuration items; to determine each design's compatibility with the requirements for the configuration item; to evaluate the degree of definition and assess the technical risk associated with the selected manufacturing methods and processes; to establish the existence and compatibility of the physical and functional interfaces among the configuration items and other items of equipment, facilities, software and personnel; and, as applicable, to evaluate the preliminary operational and support documents.* (ISO/IEC/IEEE 24765 2009)

Source

ISO/IEC/IEEE. 2009. *Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab)*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2009.

Discussion

None.

Principle (glossary)

> 1) *a fundamental truth or proposition that serves as the foundation for a system of belief or behaviour or for a chain of reasoning.* (Oxford Dictionaries Online 2012)
>
> 2) *a rule or belief governing one's behavior.* (Oxford Dictionaries Online 2012)

Source

(1) and (2) Oxford Dictionaries Online S.v. "Principle" Accessed February 20, 2012. Available at http:/ / oxforddictionaries.com/definition/concept.

Discussion

A principle is a rule of conduct or behavior. To take this further, a principle is a "basic generalization that is accepted as true and that can be used as a basis for reasoning or conduct." (WordWeb.com) A principle can also be thought of as a "basic truth or law or assumption." [ibid.]

Principles depend on concepts in order to state a "truth." Hence, principles and concepts go hand in hand; principles cannot exist without concepts and concepts are not very useful without principles to help guide the proper way to act (Lawson and Martin 2008).

Work Cited

Lawson, H., and J.N. Martin. 2008. "On the Use of Concepts and Principles for Improving Systems Engineering Practice". Proceedings of the 18th Annual International Council on Systems Engineering (INCOSE) International Symposium, 5-19 June 2008, Utrecht, The Netherlands.

Problem (glossary)

A concern that has a probability of occurrence equal to one, a consequence of occurrence greater than zero, and a time-frame that is current. A problem is an event that has occurred and has a negative impact to the project. (Conrow 2008)

Source

Conrow, E. 2008. "Risk Analysis for Space Systems". Space Systems Engineering and Risk Management Symposium, 27-29 February, 2008, Los Angeles, CA, USA.

Discussion

Defines problem in terms of probablity of occurrence, consequence of occurrence, and time-frame; all of which are measurable.

Process (glossary)

> *(1) A process is a set of interrelated or interacting activities which transforms inputs into outputs* (ISO 9000:2005)
>
> *(2) A set of activities, methods, practices, and transformations that people use to develop and maintain systems and associated products. (SEI 2007)*
>
> *(3) Process Purpose: high level objective of performing the process and the likely outcomes of effective implementation of the process.* NOTE The implementation of the process should provide tangible benefits to the stakeholders. (ISO/IEC 12207:2008)
>
> *(4) Process Outcome: observable result of the successful achievement of the process purpose* (ISO/IEC 12207:2008)

Sources

(1) ISO/IEC. 2000. *International standards for quality management.* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO 9000:2000.

(3) and (4) ISO/IEEE. 2008. *Systems and Software Engineering — Software Life Cycle Processes*. Geneva, Switzerland: International Organization for Standards (ISO)/Institute of Electrical & Electronics Engineers (IEEE) Computer Society, ISO/IEEE 12207:2008(E).

Discussion

These definitions are taken from the INCOSE Systems Engineering Handbook, and are based on standard ISO terminology.

Procurement (glossary)

The overarching function that describes the activities and processes to acquire goods and services. (Purchasing Insight 2012)

Sources

Purchasing Insight. 2012. "Definition of Procurement – Procurement vs Purchasing." (online). New York, NY, USA: Purchasing Insight, Purchase to Pay, Purchasing & Procurement Process, Electronic Invoicing. Available at: http://purchasinginsight.com/resources/what-is/definition-of-procurement-procurement-vs-purchasing/

Discussion

"The terms “Purchasing” and “Procurement” are often used, incorrectly, interchangeably. Importantly, and distinct from “purchasing”, procurement involves the activities involved in establishing fundamental requirements, sourcing activities such as market research and vendor evaluation and negotiation of contracts. It can also include the purchasing activities required to order and receive goods."

Product (glossary)

(1) *A system considered from the point of view of a physical “system end product” (ANSI/EIA 2003) made of system elements that may include hardware, software, infrastructure and support services. The people and organizational aspects of the “whole system” of which the “product system” forms a part have to be considered in the design, but are provided by another organization.* (INCOSE UK Chapter 2010)

(2) *An artifact that is produced, is quantifiable, and can be either an end item in itself or a component item.* (PMI 2008)

Source

(1) INCOSE UK Chapter. 2010. *Applying Systems Engineering to In-Service Systems: Supplementary Guidance to the INCOSE Systems Engineering Handbook*. Version 3.2, issue 1.0. Foresgate, UK: International Council on Systems Engineering (INCOSE) UK Chapter: 10, 13, 23.

(2) PMI. 2008. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*, 4th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

Discussion

This definition is a systems engineering definition, which is consistent with the concept of a system-of-interest (SoI) focused on the product system to be delivered to an acquirer who will use it to help deliver user outcomes.

Product System (glossary)

(1) *A system context for which the system-of-interest (SoI) is a product.* (Created for SEBoK)

(2) *A system considered from the point of view of a physical "system end product" (ANSI/EIA 2003) made of system elements that may include hardware, software, infrastructure and support services. The people and organizational aspects of the "whole system" of which the "product system" forms a part have to be considered in the design, but are provided by another organization.* (ISO/IEC/IEEE 15288 2008)

Sources

(1) This definition was developed for the SEBoK.

(2) This definition was extended from: ISO/IEC. 2008. Systems and Software Engineering -- System Life Cycle Processes. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions. ISO/IEC/IEEE 15288:2008.

Discussion

Definition (1) is has been created for the SEBoK to distinguish from a product (glossary) from a product system.

Definition (2) is a systems engineering definition, which is consistent with the concept of a SoI focused on the product system to be delivered to an acquirer who will use it to help deliver user outcomes.

See the Engineered Systems discussion.

Program (glossary)

A group of related projects managed in a coordinated way to obtain benefits and control not available from managing them individually. Programs may include elements of related work outside of the scope of the discrete projects in the program.(PMI 2008)

Source

PMI. 2008. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide),* 4th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

Discussion

The term "program" is also used as another name for a large project. "Program management" is sometimes used to denote management of a portfolio of projects within a business unit.

Program Management (glossary)

> *The application of knowledge, skills, tools, and techniques to a program to meet the program requirements and to obtain benefits and control not available by managing projects individually.* (PMI 2013)

Source

PMI. 2013. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*. 5th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

Discussion

See also program.

Project (glossary)

> (1) *A temporary endeavor undertaken to create a unique product, service, or result.* (PMI 2013)
>
> (2) *a development effort consisting of both technical and management activities for the purpose of engineering a system.* (extract from (ANSI/EIA 2003))
>
> (3) *endeavour with defined start and finish criteria undertaken to create a product or service in accordance with specified resources and requirements.* (ISO/IEC/IEEE 2015)

Source

(1) PMI. 2013. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*. 5th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

(2) ANSI/EIA. 2003.*Processes for Engineering a System*. Philadelphia, PA, USA: American National Standards Institute (ANSI)/Electronic Industries Association (EIA), ANSI/EIA-632-1998.

(3) ISO/IEC/IEEE. 2015. *Systems and Software Engineering -- System Life Cycle Processes*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions / Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 15288:2015.

Discussion

These three definitions, taken together define the essence of a project: namely, a group of coordinated work activities that utilizes resources to achieve specified objectives within a prescribed time frame. Objectives include requirements for a product, service, or enterprise endeavor but objectives may be broader than technical requirements; for example, an objective may be to develop a new product or product line or to support a new type of service for new customers. In addition to providing technical leadership, systems engineers often manage the technical aspects of projects.

Project Management (glossary)

(*1) The application of knowledge, skills, tools, and techniques to project activities to meet the project requirements.* (PMI 2013)

(*2) The collection of work activities concerned with planning and estimating, measuring and controlling, leading and coordinating, and managing risk factors for a project.* (Fairley 2009)

Sources

(1) PMI. 2013. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*. 5th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

(2) Fairley, R.E. 2009. *Managing and Leading Software Projects*. Hoboken, NJ, USA: John Wiley & Sons.

Discussion

See also project.

Prototype (glossary)

(1) ***Prototype - hardware*** - A specification-compliant production readiness demonstration model developed under engineering supervision that represents what manufacturing should replicate. All design engineering and production engineering must be complete, and the assembly must be under configuration control. *(Fairley 2009, p 74-75), (Forsberg, Mooz, Cotterman 2005, p 432)*

(2) ***Prototype - software*** *- A term currently with multiple meanings. A "rapid prototype" is usually a software requirements demonstration model, which provides a simulated representation of the software functionality and operator interface. The model facilitates early buyer-developer agreement on the design approach. A software prototype may also be a technical demonstration model. Except with "Evolutionary Prototypes," the code is usually discarded once the model has served its purpose.* (Forsberg, Mooz, Cotterman 2005, p 432)

(3) ***Prototype - software*** *- Software prototypes are constructed to investigate a situation or to evaluate a proposed approach to solving a technical problem. ... When building a prototype, we keep the knowledge we have gained but we do not use the code in the deliverable version of the system* (Fairley 2009, p 74-75)

Sources

Discussion

None.

Proving (glossary)

> *Subjecting a system or element to a test, experiment, comparison, analysis, or the like, to determine quality, amount, acceptability, characteristics, correctness, compliance with requirements, etc.* (Dictionary.com 2012)

Sources

Dictionary.com. 2012. "Prove." Available at http://dictionary.reference.com/browse/prove [1].

Discussion

This definition is the gerund of the Dictionary.com definition. In systems engineering, proving a system generally consists of verification and validation.

References

[1] http://dictionary.reference.com/browse/prove

Purpose (glossary)

> *What the system is for, and why the different stakeholders are willing to participate in the system lifecycle.* (Blockley and Godfrey 2000)

Source

Blockley, D., and P. S. Godfrey. 2000. *Doing It Differently - Systems for Rethinking Construction*. Telford, UK: Thompson Telford, Ltd.

Discussion

None.

Purposeful (glossary)

> *A purposeful system is free to determine its own goals needed to achieve an outcome.* (Ackoff 1971)

Sources

Ackoff, R.L. 1971. "Towards a System of Systems Concepts", *Management Science*, 17(11) USA.

Discussion

This is the theorectical system science definition. A goal is a specific task achievable in a set time, while an objective is a desired outcome which need to be achieved (or partially achieved) within a time limit. Purposful systems can be given a problem to solve. Humans, and sufficiently complex machines, are purposeful.

Purposive (glossary)

> *Purposive systems have multiple goals (pre-determined outcomes, over a set time period), with some shared outcome.* (Ackoff 1971)

Sources

Ackoff, R.L. 1971. "Towards a System of Systems Concepts," *Management Science,* 17(11), USA.

Discussion

This is the theorectical system science definition. Purposive systems can be used to do specific things. Such a system may have set functions or some freedom to choose how to achieve the goal. If it has memory it may develop processes describing the behaviors needed for defined goals. Most machines or software systems are purposive; as are humans performing set tasks on demand.

Q

Qualification (glossary)

Conducted to prove that the system design meets its requirements ***with a predetermined margin*** *above expected operating conditions, for instance by using elevated environmental conditions for hardware.* (INCOSE 2011,128)

Proof that the design will survive in its intended environment ***with margin****. The process includes testing and analyzing hardware and software configuration items to prove that the design will survive the anticipated accumulation of acceptance test environments, plus its expected handling, storage, and operational environments plus a* ***specified qualification margin****. Qualification testing usually includes temperature, vibration, shock, humidity, software stress testing, and other selected environments. Qualification by similarity may be used if the item in question is sufficiently similar to a qualified item and the planned use is also sufficiently similar so as to not invalidate the previous qualification evidence and decision.* (Mooz, Forsberg, Cotterman 2003, 270)

Sources

(1) INCOSE. 2011. Systems Engineering Handbook, version 3.2.1. INCOSE-TP-2003-002-03.2.1.

(2) Mooz, H., K. Forsberg, K., H. Cotterman. 2003. *Communicating Project Management.* Hoboken, NJ, USA: John Wiley and Sons.

Discussion

The term "qualification" is not well understood, and when asked "Where do the qualification limits come from?" people often say "From the specification." It is the systems engineer's responsibility to determine what the qualification margins should be, with concurrance from the project manager and customer, and then put them into the specification. Lack of understanding of the significance of "Qualification" lead to the death of seven astronauts in the Challenger accident. According to testimony presented in the 1986 Rogers Commission Report on the Space Shuttle disaster, the question was asked in the launch commit meeting the night before the flight, "Are the O-Rings qualified to operate between 40º F and 90ºF (+4ºC and 32ºC) or not?" There was no answer. Since the temperature was expected to be (and indeed was) 29ºF (-2ºC) at launch, no further discussion should have been needed and the launch should have been postponed. A rule: Never operate outside the qualified range.

Quality (glossary)

> *Ability of a product, service, system, component, or process to meet customer or user needs, expectations, or requirements.* (ISO/IEC/IEEE 2010)

Sources

ISO/IEC/IEEE. 2010. *Systems and Software Engineering -- Vocabulary (SEVocab)* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronic Engineers (IEEE) 2009 ISO/IEC/IEEE 24765:2010 [database online]. Available from http://pascal.computer.org/sev_display/index.action.

Discussion

None.

R

Rationale (glossary)

Argument that provides the justification for the selection of an engineering element. (Faisandier 2012)

Sources

Faisandier, A. 2012. *Systems Architecture and Design*. Belberaud, France: Sinergy'Com.

Discussion

None.

Recovery (glossary)

The level of functioning to which a system returns after experiencing a disruption. (DHS 2010)

Sources

DHS. 2010. "'Risk and Resilience: Exploring the Relationship". In: Kahan, J. (ed.). Arllington, VA: Department of Homeland Security (DHS), p. A-20.

Discussion

Within the context of resilience, the Department of Homeland Security is regarded as the authoritative source for definitions and other concepts related to resilience.

Recursion (glossary)

> *The process of defining or generating a process or data structure in terms of itself.* (ISO/IEC/IEEE 24765 2010)

Sources

ISO/IEC/IEEE. 2010. *Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab)*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2010.

Discussion

In the systems engineering context, recursion is used in re-application of the same standard (in the case ISO/IEC 15288) as a system is decomposed into system elements and where the elements are systems as well. The standard is re-applied for each system-of-interest (SoI) on each level.

Reductionism (glossary)

(1) an approach to understanding the nature of complex things by reducing them to the interactions of their parts. (M'Pherson 1974)

(2) a view that a complex system is nothing but the sum of its parts, and that it can be fully understood by examination of those parts. (M'Pherson 1974)

Source

(1) and (2) M'Pherson, P, K. 1974. "A perspective on systems science and systems philosophy." *Futures* 6(3) (June 1974):219-239.

Discussion

None.

Redundancy (glossary)

> *In fault tolerance, the presence of auxiliary components in a system to perform the same or similar functions as other elements for the purpose of preventing or recovering from failures.* (ISO/IEC/IEEE 24765:2010)

Sources

ISO/IEC/IEEE. 2009. *Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab).* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2009.

Discussion

None.

Regularity (glossary)

> *A uniformity or similarity that exists in multiple entities or at multiple times.* (von Bertalanffy 1968).

Sources

von Bertalanffy, L. 1968. *General System Theory: Foundations, Development, Applications*, Revised ed. New York, NY, USA: Braziller.

Discussion

The existence of similarities and differences between systems from different domains is one of fundamental ideas behind systems thinking (see Concepts of Systems Thinking)

Reliability (glossary)

> *The probability of a system or system element performing its intended function under stated conditions without failure for a given period of time.* -- modified slightly from (American Society for Quality 2011)

Sources

American Society for Quality. 2011. Glossary: Reliability. Accessed on 11 September 2012. Available at http://asq.org/glossary/r.html.

Discussion

This definition is similar to the one found in the *Defense Acquisition Guidebook*, and the commonly used texts. (DAU 2010) It has four important parts. First, reliability is defined as a probability that a system or system element performs some function. That function must be explicitly defined. Second, the stated operating conditions (which can include environment, load, and any other factor affecting life) must be explicitly stated. Third, a failure must be defined. Last, the appropriate time scale must be specified. This time scale can be chronological, or it can by cycles of operation, miles, landing, or any other measure that is related to the assumed failure mechanism.

Remote sensing (glossary)

> the process of detecting and monitoring the physical characteristics of an area by measuring its reflected and emitted radiation at a distance (typically from satellite or aircraft).

USGS. n.d. Accessed on May 15, 2022. Available: https:/ / www. usgs. gov/ faqs/ what-remote-sensing-and-what-it-used

Annotation

None.

Reparability (glossary)

a system resilience principle which states that a system should have the capability of being brought up to partial or full functionality over a specified period of time and in a specified environment. Jackson and Ferris (2016)

Source

Jackson, Scott, and Timothy Ferris. 2013. "Resilience Principles for Engineered Systems." Systems Engineering 16 (2):152-164.

Requirement (glossary)

Statement that identifies a product or process operational, functional, or design characteristic or constraint, which is unambiguous, testable or measurable, and necessary for product or process acceptability. (ISO/IEC 2007)*

*includes product, service, or enterprise.

Source

ISO/IEC. 2007. *Systems and Software Engineering -- Recommended Practice for Architectural Description of Software-Intensive Systems*. Geneva, Switzerland: International Organization for Standards (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 42010:2007.

Discussion

A requirement is “a statement that identifies a system, product or process characteristic or constraint, which is unambiguous, clear, unique, consistent, stand-alone (not grouped), and verifiable, and is deemed necessary for stakeholder acceptability.” (INCOSE 2010)

INCOSE. 2010. *Systems Engineering Handbook: A Guide for System Life Cycle Processes and Activities*. Version 3.2.1. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.1: 362.

Resilience (glossary)

1. *Ability to maintain capability in the face of adversity" (INCOSE)*

2. *Ability to adapt to changing conditions and prepare for, withstand, and rapidly recover from disruption.* (DHS 2010)

3. *Ability to provide required capability when faced with adversity* . (Brtis and McEvilley 2019)

Source

3) Brtis, J.S. and M.A. McEvilley. 2019. *Systems Engineering for Resilience.* The MITRE Corporation. MP 190495. Accessed April 2, 2021. Available at https:/ / www. researchgate. net/ publication/ 334549424_Systems_Engineering_for_Resilience.

Discussion

The above definition is the official definition of the US government. The same definition appears in both sources. Although the government's interest is in the resilience of infrastructure systems, the definition is sufficiently general to apply to any human-made system. The word has been applied in material sciences, ecology, and psychology. However, those definitions do not apply here. Some sources use the word "resiliency," but "resilience" is more common.

If there is discussion around why this is the appropriate definition, include here. If not, please replace with "None".

Restructuring (glossary)

a system resilience principle that states a system should be capable of restructuring itself. Jackson (2016)

Source

Jackson, Scott. 2016. "Principles for Resilient Design - A Guide for Understanding and Implementation." In IRGC Rresource Guide on Resilience, edited by I. Linkov. University of Lausanne, Switzerland: International Risk Governance Council (IRGC).

Discussion

Also called reorganization.

Reverse Engineering (glossary)

(1) A process of documenting the functions and behaviors of a device or system by analysis and test. (Created for SEBoK)

(2) The reverse engineering process applied to a product, service or enterprise consists of performing a bottom up approach from physical aspects and properties to functional ones then to identify its characteristics as requirements. (Created for SEBoK)

(3) Reverse engineering is the process of discovering the technological principles of a device, object, or system through analysis of its structure, function, and operation. It often involves taking something (e.g., a mechanical device, electronic component, software program, or biological, chemical, or organic matter) apart and analyzing its workings in detail to be used in maintenance, or to try to make a new device or program that does the same thing without using or simply duplicating (without understanding) the original.' (Wikipedia Contributors 2012)'

Source

(1) and (2) These definitions were developed for the SEBoK.

Rhumb Line (glossary)

A rhumb line, or its synonym loxodrome (used in geometry navigation), is a curve which crosses meridians of longitude at a constant bearing.

Source

ISO TC211. "Rhumb line." In: *ISO TC211 Multilingual Glossary.* Version from 2020-06-02. Concept ID: 2083. Available at: https://isotc211.geolexica.org/concepts/2083/.

Discussion

None.

Risk (glossary)

(1) Risk is a measure of the potential inability to achieve overall program objectives within defined cost, schedule, and technical constraints and has two components: The probability (or likelihood) of failing to achieve a particular outcome andThe consequences (or impact) of failing to achieve that outcome. (DAU, 2003)A risk has a probability of occurrence that is greater than zero but less than one, a consequence of occurrence greater than zero, and a time-frame in the future. (Conrow 2008)

(2) In the domain of catastrophic risk analysis, such as for terrorist attacks or natural disasters, risk has three components: Threat (the probability that a specific target is attacked in a specific way during a specified period)Vulnerability (the probability that damage occurs given a threat), andConsequence (the magnitude and type of damage resulting from an attack or disaster). (Willis et al. 2005)(1) Conrow, E. 2008. Risk Analysis for Space Systems. Paper presented at Space Systems Engineering and Risk Management Symposium, 27-29 February, 2008, Los Angeles, CA, USA. (1) DAU. 2003. Risk Management Guide for DoD Acquisition: Fifth Edition. Ft. Belvoir, VA, USA: Defense Acquisition University (DAU)/U.S. Department of Defense, Fifth Edition, Version 2. (2) Willis, H.H., A.R. Morral, T.K. Kelly, and J.J. Medby. 2005. Estimating Terrorism Risk. Santa Monica, CA: The RAND Corporation, MG-388. Definition (1) or related definitions are in widespread project risk management use. The definition has been extended to include time-frame. Definition (2) or related definitions are in widespread use for catastrophic risk analysis (e.g., threat, disaster, information assurance). Definition (1) defines risk in terms of probablity of occurrence, consequence of occurrence, and time-frame; all of which are measurable. Likewise, definition (2) defines risk in terms of threat, vulnerability, and consequence of occurrence; all of which are measurable.

Risk Management (glossary)

(1) An organized process for identifying and handling risk factors. (ISO/IEC/IEEE 2017)

(2) an organized means of identifying and measuring risk (risk assessment) and developing, selecting, and managing options (risk analysis) for resolving (risk handling) these risks. (ISO/IEC/IEEE 2017)

(3) organized, analytic process to identify what might cause harm or loss (identify risks); to assess and quantify the identified risks; and to develop and, if needed, implement an appropriate approach to prevent or handle causes of risk that could result in significant harm or loss. (ISO/IEC/IEEE 2017)

Discussion

None.

Service (glossary)

> *An activity required by one or more users who have agreed on the terms of outcomes and quality of service without details to how it is provided. A service is also, simply put, an act of help or assistance. In a more formal sense:*
>
> *Services are activities that cause a transformation of the state of an entity (people, product, business, and region or nation) by mutually agreed terms between the service provider and the customer.* (Chang 2010)

Source

Chang, C. M. 2010. *Service Systems Management and Engineering: Creating Strategic Differentiation and Operational Excellence.* New York, NY, USA: John Wiley & Sons, Inc. ISBN 978-0-470-42332-5.

Discussion

In the service-dominant logic (S-DL) for marketing, service is the application (through deeds, processes, and performances) of specialized operant resources (knowledge and skills) for the benefit of another entity or the entity itself. (Vargo and Akaka 2009)

In the field of service science, management, and engineering (SSME), the following is offered:

> Services are processes, performances, or experiences that one person or organization does for the benefit of another – such as custom tailoring suit, cooking a dinner to order, driving a limousine, mounting a legal defense, setting a broken bone, teaching a class, or running a business's information technology infrastructure and applications. In all cases, service involves deployment of knowledge, skills, and competences that one person or organization has for the benefit of another (Vargo and Lusch 2004), often done as a single, customized job. And in all cases, service requires substantial input from the customer or client (Sampson 2001) – how else could your steak be customized for you unless you tell your waiter how you want it prepared? (http:/ / en. wikipedia. org/ wiki/ Service_Science,_Management_and_Engineering)

Furthermore:

- Services are economic activities offered by one party to another, most commonly employing time-based performances to bring about desired results in recipients themselves or in objects or other assets for which purchasers have responsibility. In exchange for their money, time, and effort, service customers expect to obtain value from access to goods, labor, professional skills, facilities, networks, and systems; but they do not normally take ownership of any of the physical elements involved. (Lovelock & Wirtz 2007)
- A service is a time-perishable, intangible experience performed for a customer acting in the role of a co-producer. (Fitzsimmons & Fitzsimmons 2007)
- The application of competences (knowledge, skills and resources) by one entity for the benefit of another entity in a non-coercive (mutually agreed and mutually beneficial) manner.
  - Value co-creation interactions (typically with well-defined customer-provider entities as parties who initiate, directly or indirectly, front-stage and back-stage activities in anticipation of value results)
  - An economic activity offered by one party to another, most commonly employing time-based performances to bring about desired transformation results in recipients themselves or in objects or other assets for which purchasers are responsible. In exchange for their money, time and effort, service customers expect to obtain value from the access to goods, labour, professional skills, facilities, networks and systems; but they do not normally take ownership of any of the physical elements involved. (IfM and IBM 2008)

Service System (glossary)

> *A dynamic configuration of resources (people, technology, organizations and shared information) that creates and delivers value between the provider and the customer through services.* (IfM and IBM 2008)

Sources

IfM and IBM. 2008. "Succeeding through Service Innovation: A Service Perspective for Education, Research, Business and Government." University of Cambridge Institute for Manufacturing. Cambridge, UK. cited by Spohrer, J. and P. Maglio. 2010. "Service Science: Toward a Smarter Planet." In *Introduction to Service Engineering*. Ed. G Salvendy and W Karwowski. 3-30. Hoboken, NJ, USA: John Wiley & Sons, Inc.

Discussion

This dynamic configuration is illustrated in the system coupling diagram (Lawson 2010) where a situation (need for a service) is met by (interacts with) a respondent system (service system) based upon the use of system assets. A service system can also be thought of as a collection of entities that performs the operations, administration, management and provisioning (OAM&P) of resources that together provide the opportunity to co-create value by both the service provider and the service consumer.

The Cambridge white paper defines a service system in this manner (IfM and IBM 2008):

> Service systems are dynamic configurations of resources (people, technology, organisations and shared information) that can create and deliver service while balancing risk-taking and value co-creation. The dynamics are in part due to the ongoing adjustments and negotiations that occur in all systems involving people. People are the ultimate arbiters of value and risk in service systems (in part because people are legal entities with rights and responsibilities). Service systems are complex adaptive systems.

Service Systems Engineering (glossary)

(1) Service systems engineering (SSE) is the application of systems engineering principles and concepts in the development, delivery, operation, and life cycle management of service systems. The key focus of SSE is on the transactions between a service (glossary) provider and service consumers. The consumer can be an individual, an organization, or even an entire enterprise. (Created for SEBoK)

(2) A multidiscipline that addresses a service system from a life-cycle, cybernetic, and customer perspective. (Tien and Berg 2003)

Source

(1) This definition was developed for the SEBoK.

(2) Tien, J.M and D. Berg. 2003. "A Case for Service Systems Engineering." *Journal of Systems Science and Systems Engineering.* 12(1) (March 2003): 13-38.

Discussion

Though "service systems engineering" (SSE) is used commonly within the field of systems engineering, few formal definitions are provided within the literature. Tien and Berg (2003) provides definition (1), which includes the concepts that multiple disciplines must be utilized to manage customer needs and expectations of a service system throughout the systems life cycle. This aligns with the notion of a service as something akin to a support system for an additional system (e.g. a call center or information technology (IT) support system). The SEBoK authors, however, believe that a more holistic view of SSE is beneficial to the discussion and in understanding how it is addressed within the literature. The author team developed definition (1) to address these concerns.

Service Value Chain (glossary)

The progression of a service opportunity from beginning to end. (FieldSVC 2005)

Sources

FieldSVC. 2005. "The Service Value Chain." (online). USA: Field Service Value Chain (FieldSVC). Accessed on 11 September 2012. Available at: http:/ / www. fieldsvc. com/ Files/ White%20Paper%20-%20The%20Service%20Value%20Chain.pdf.

Discussion

None.

Set Driver (glossary)

Fundamental design decisions that define the platform characteristics that enable current and future missions, e.g. airframe and engine for a UAV and structure and engine for a car. (Specking et al. 2018)

Source

Specking, E., C. Whitcomb, G. Parnell, S. Goerger, E. Kundeti, and N. Pohl. 2018. “Literature Review: Exploring the Role of Set-Based Design in Trade-off Analytics.” *Naval Engineers Journal.* 130 (2): 51-62.

Discussion

None.

Set Modifiers (glossary)

> *Design decisions that are 'added on' to the platform and can be modified to adapt to new missions and scenarios, e.g., sensors, weapons, communications equipment for a UAV and tires, type of oil, navigation software for a car.* (Specking et al. 2018)

Source

Specking, E., C. Whitcomb, G. Parnell, S. Goerger, E. Kundeti, and N. Pohl. 2018. "Literature Review: Exploring the Role of Set-Based Design in Trade-off Analytics." *Naval Engineers Journal.* 130 (2): 51-62.

Discussion

None.

Set-Based Design (glossary)

> *A complex design method that enables robust system design by 1) considering a large number of alternatives, 2) using experts who design from their own perspectives and use the intersection between their individual sets to optimize a design, and 3) establishing feasibility before making decisions.* (Singer, Doerry, and Buckley 2009)

Source

Social System (glossary)

> *An open system which includes human elements.* (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

Several definitions of "social systems" exist. For example, "the people in a society considered as a system organized by a characteristic pattern of relationships," (WordNet 2012) or "organized boundary systems of social roles, behaviors, and practices developed to maintain values and the mechanisms to regulate the practices and roles *(Taber's Cyclopedic Medical Dictionary 2009). These definitions, however, generally arise from sociology and do not take into account a "systems thinking" perspective. The definition provided above has been created for the SEBoK based on the systems science definition. See the Engineered Systems topic for additional discussion.*

Works Cited

Taber's Cyclopedic Medical Dictionary, 21st Edition, s.v. "social systems", 2009.

WordNet: A lexical database for English, version 3.1, s.v. "social system", 2012.

Sociotechnical System (glossary)

> *An engineered system which includes a combination of technical and human or natural elements.* (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

The term "sociotechnical system" is used frequently in the literature, and almost all definitions state simply "a system incorporating humans and technology". The definition above has been created for the SEBoK alongside the definition of an "engineered system" - in the context of the SEBoK, sociotechnical systems are considered systems which are intentionally designed to incorporate human beings. See the Engineered Systems topic for additional information. For a brief overview of some common characteristics of sociotechnical systems, please see (ComputingCases.org 2012), a resource designed to support education in ethical issues in computing.

Specialty Engineering (glossary)

(1) A component of Systems Engineering that complements the technical activities required to deliver a project. It typically deals with engineering that affects the performance, safety, usability, cost certainty, constructability, deliverability and lifecycle of the product outside of the normal functional aspects of engineering. (INCOSE 2015)

(2) The collection of those narrow disciplines that are needed to engineer a complete system. (Elowitz 2006)

Source

(1) INCOSE. 2015. INCOSE Infrastructure Working Group. Available at: INCOSE https://www.incose.org/docs/default-source/ Working-Groups/ infrastructure-wg-documents/ 005-specialty-engineering-pamphlet.pdf?sfvrsn=9c2c82c6_6.

(2) Elowitz, M. 2006. "Specialty Engineering as an Element of Systems Engineering." Presentation to Enchantment Chapter, INCOSE. Albequerque, NM, USA, 9 August 2006.

Discussion

The definition of "narrow disciplines" is context dependent, and can include traditional domain disciplines (electrical engineering, mechanical engineering, etc.) as well as integrative disciplines (human systems engineering, safety engineering, etc.).

Stage (glossary)

A period within the life cycle of an entity that relates to the state of its description or realization. (ISO/IEC/IEEE 15288)

Source

ISO/IEC/IEEE. 2015. *Systems and Software Engineering -- System Life Cycle Processes*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions / Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 15288:2015.

Discussion

A lifecycle stage may also be referred to as a phase.

Stakeholder (glossary)

(1) *Individual or organization having a right, share, claim, or interest in a system or in its possession of* characteristics that meet their needs and expectations *(ISO/IEC/IEEE 2015)*

(2) *Individual or organization having a right, share, claim, or interest in a system or in its possession of characteristics that meet their needs and expectations; N.B. Stakeholders include, but are not limited to end users, end user organizations, supporters, developers, producers, trainers, maintainers, disposers, acquirers, customers, operators, supplier organizations and regulatory bodies.* (ISO/IEC June 2010)

(3) *An individual, team, or organization (or classes thereof) with interests in, or concerns relative to, a system.* (ISO/IEC 2007)

(4) *A stakeholder in an organisation is (by definition) any group or individual who can affect or is affected by the achievement of the organisation's objectives.* (Freeman 1984)

Source

(1) ISO/IEC/IEEE. 2015. *Systems and Software Engineering - System Life Cycle Processes*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission/Institute of Electrical and Electronics Engineers (IEC), ISO/IEC/IEEE 15288:2015 (E).

(2) ISO/IEC. June 2010. *Software and Systems Engineering -- Life Cycle Processes -- Requirements Engineering*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), ISO/IEC CD 29148.

(3) ISO/IEC. 2007. *Systems Engineering--Application and Management of the Systems Engineering Process*. Geneva, Switzerland: International Organization for Standards (ISO)/International Electrotechnical Commission (IEC), ISO/IEC 26702:2007.

(4) Freeman, R.E. 1984. *Strategic Management: A stakeholder approach*, Boston, Pitman

Discussion

None.

Stakeholder Needs and Requirements (glossary)

(1a) *Stakeholder needs include elicitation of needs, wants, desires, expectations and perceived constraints of identified stakeholders. Needs concentrate on system purpose and behavior, and are described in the context of the operational environment and conditions.* (ISO/IEC/IEEE 15288, 2023, Section 6.4.2)

(1b) *Stakeholder requirements are transformed from the stakeholder needs to objectively adequate, structured and more formal statements.* (ISO/IEC/IEEE 29148, 2018, Section 5.2.3)

(1c) *Stakeholder requirements express the intended interaction the system will have with its operational environment and that are the reference against which each resulting operational capability is validated. The stakeholder requirements are defined considering the context of the system of interest with the interoperating systems and enabling systems. This also includes consideration of laws and regulations, environmental restrictions, and ethical values.* (ISO/IEC/IEEE 15288, 2023, Section 6.4.2)

Source

ISO/IEC/IEEE. 2023. *Systems and Software Engineering -- System Life Cycle Processes*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions / Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 15288:2023.

ISO/IEC/IEEE. 2018. *Systems and software engineering — Life cycle processes — Requirements engineering*. Geneva, Switzerland: International Organisation for Standardisation / International Electrotechnical Commissions / Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 29148:2018.

Discussion

Both definitions are taken from the introduction to the "Stakeholder Requirements Definition Process" in ISO/IEC 15288; there is no formal definition of the term "stakeholder requirement" in the standard.

For a full discussion of the role and importance of stakeholder needs in systems engineering see the Stakeholder Needs Definition article.

State (glossary)

> *(1) The values of key system element qualities or properties at a given time.* (Ackoff 1971)
>
> *(2) A description of the current or future potential, or health of the system.* (Ackoff 1971)

Source

(1) and (2) Ackoff, R.L. 1971. "Towards a System of Systems Concepts." *Management Science.* 17(11):USA.

Discussion

The first definition is a mathematical one, taken from the cybernetic world.

The second is used more practial, and is used by the system operations or sustainment community.

Statistical Process Control (glossary)

> *Statistically based analysis of a process and measures of process performance, which identify common and special causes of variation in process performance and maintain process performance within limits.* (ISO/IEC/IEEE 2009)

Sources

ISO/IEC/IEEE. 2009. *Systems and Software Engineering - System and Software Engineering Vocabulary*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). Discussion

None.

Synectics (glossary)

A set of process tools which can be used successfully in a variety of situations, either in a specific sequence (as in the original invention model) or individually according to the needs of the situation. The result is a variety of meeting models and techniques for enhancing personal effectiveness. (Nolan 2003)

Sources

Nolan, V. 2003. "Whatever Happened to Synectics?" *Creativity and Innovation Management.* 12(1) (March 2003): 24.

Discussion

None.

Synergy (glossary)

(1) In an organization synergy is the ability of a group to outperform even its best individual member. (Buchanan and Huczynski,1997).

(2) A construct or collection of different elements working together to produce results not obtainable by any of the elements alone. The elements, or parts, can include people, hardware, software, facilities, policies, documents: all things required to produce system-level results. (Blanchard 2004).

Sources

(1) Buchanan, D. and A. Huczynski. 1997. *Organizational behavior, introductory text,* 3rd edition, p. 276. Upper Saddle River, NJ, USA: Prentice Hall.

(2) Blanchard, B. 2004. *System Engineering Management,* p. 8. Hoboken, N, USAJ: John Wiley.

Discussion

Synergy is two or more things functioning together to produce a result not independently obtainable. The term synergy comes from the Greek word synergia meaning "working together". It is often used in business or other human activitiy systems to describe outcomes which can only be achieved by encouraging people or organizations to work together, often through encouraging friction or creative tensions between them. In medicine synergy is used to describe combinations of drugs which interact in ways that enhance or magnify one or more effects, or side-effects, of those drugs. This may give both positive and negative effects.

Definition (2) is typical of the use of the term synergy in systems engineering texts to describe how system behavior emerges from the interaction between elements. In this sense synergy is closely related to emergence.

Synthesis (glossary)

> *The combination of parts, elements, or diverse conceptions into a coherent whole; to put together* (INCOSE 1998, p. 236)

Sources

INCOSE. 1998. "INCOSE SE Terms Glossary". In *INCOSE Concepts and Terms*. Seattle, WA: International Council on Systems Engineering.

Discussion

None.

System (glossary)

> *(1) A set of elements in interaction.* (von Bertalanffy 1968)
>
> *(2) combination of interacting elements organized to achieve one or more stated purposes (ISO/IEC/IEEE 2015)*
>
> (3) A system is an arrangement of parts or elements that together exhibit behavior or meaning that the individual constituents do not. (INCOSE Fellows, 2019)

Source

(1) von Bertalanffy, L. 1968. *General System Theory: Foundations, Development, Applications.* Revised ed. New York, NY, USA: George Braziller, Inc.

(2) ISO/IEC/IEEE. 2015. *Systems and Software Engineering - System Life Cycle Processes.* Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 15288:2015. The second definition is an expanded version of the ISO/IEC/IEEE version.

(3) INCOSE Fellows Briefing to INCOSE Board of Directors, January 2019.

Discussion

Definition (1) is the System Science definition and applies to all systems: natural, social or technical.

Definition (2) is the recognized definition for systems engineers. Elements in this sense may include hardware, software, firmware, people, information, techniques, facilities, services, related natural artifacts and other support elements. This definition should be restricted to engineered systems which are created with a purpose which provides value to one or more beneficiaries.

Definition (3) was created by the INCOSE Fellows Initiative on System and Systems Engineering Definitions. This was established in 2016, to review current INCOSE definitions of SYSTEM and SYSTEMS ENGINEERING and to recommend any changes necessary to align the definitions to a) current practice, and b) the aspirations of INCOSE's 2025 Vision. At the January 2019 INCOSE Board of Directors meeting, a new INCOSE definition for "system" was approved and is given above.

Expanding on this definition, the INCOSE Fellows state:

Systems can be either physical or conceptual, or a combination of both. Systems in the physical universe are composed of matter and energy, may embody information encoded in matter-energy carriers, and exhibit observable

behaviour. Conceptual systems are abstract systems of pure information, and do not directly exhibit behaviour, but exhibit “meaning”. In both cases, the system's properties (as a whole) result, or emerge from:

· the parts or elements and their individual properties; AND

· the relationships and interactions between and among the parts, the system and its environment.

Note, definitions (1) and (2) remain applicable to the usage of this term in the current SEBoK, unless specifically stated. As the fellow initiative definition becomes more widely used we expect it to become the default definition in future releases of the SEBoK

See Introduction to Systems Fundamentals for a full discussion of the nature of systems in general and the scope of engineered systems of particular interest to systems engineering.

System Analysis (glossary)

> *A systematic investigation of a real or planned system to determine the information requirements and processes of the system and how these relate to each other and to any other system.* (ISO/IEC/IEEE 2009)

Sources

ISO/IEC/IEEE. 2009. *Systems and Software Engineering - System and Software Engineering Vocabulary*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2009.

Discussion

For a full discussion of the role and importance of system analysis in systems engineering see the System Analysis article.

System Assurance (glossary)

> *…the justified confidence that the system functions as intended and is free of exploitable vulnerabilities, either intentionally or unintentionally designed or inserted as part of the system at any time during the life cycle... This confidence is achieved by system assurance activities, which include a planned, systematic set of multi-disciplinary activities to achieve the acceptable measures of system assurance and manage the risk of exploitable vulnerabilities.* (NATO February 2010, p. 1)

Sources

NATO. 2010. Engineering for system assurance in NATO programs. Washington, DC: NATO Standardization Agency, DoD 5220.22M-NISPOM-NATO-AEP-67. February 2010.

Discussion

The NATO document is organized based on the life cycle processes in ISO/IEC 15288:2008 and provides process and technology guidance to improve system assurance.

System Boundary (glossary)

A distinction made by an observer which marks the difference between an entity he takes to be a system and its environment. (Checkland 1999, 312)

Source

Checkland, P. 1999. *Systems Thinking, Systems Practice*. New York, NY, USA: John Wiley & Sons.

Discussion

None.

System Breakdown Structure (glossary)

> *A hierarchy of elements, related life cycle processes, and personnel used to assign development teams, conduct technical reviews, and to partition out the assigned work and associated resource allocations to each of the tasks necessary to accomplish the objectives of the project.* (IEEE 2005)

Sources

IEEE. 2005. *IEEE Standard for Application and Management of the Systems Engineering Process*. Washington, DC, USA: Institute of Electrical and Electronics Engineers. IEEE 1220-2005.

Discussion

None.

System Capability (glossary)

> *The ability of a system to execute a particular course of action or achieve a desired effect, under a specified set of conditions.* (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

In the SEBoK, the terms "capability" may be used in place of "system capability", implying a capability discussed within a systems context. Please see the discussion of capability. It is important to note that "system capability" is sometimes used to distinguish between an "organizational capability" within the SEBoK.

System Context (glossary)

(1) Describes the system relationships and environment, resolved around a selected system-of-interest. (Flood and Carson 1993)

(2) Diagram defining the highest level view of a system in its environment. (Flood and Carson 1993)

Source

(1) and (2) Flood, R.L. and E.R. Carson. 1993. *Dealing with complexity: An introduction to the theory and application of systems science*, 2nd ed. New York, NY, USA: Plenum Press.

Discussion

Definition (1) describes the reason for considering context.

Definitions (2) relates context to a context diagram. This is most common way in which context is express in systems engineering. A number of context diagram notations are available.

System Coupling Diagram (glossary)

> *A paradigm that conveys the essence of what systems are used for and how systems relate to each other as portrayed in the figure* (Lawson 2010)

Sources

Lawson, H. 2010. *A Journey Through the Systems Landscape*, UK: College Publications, Kings College.

Discussion

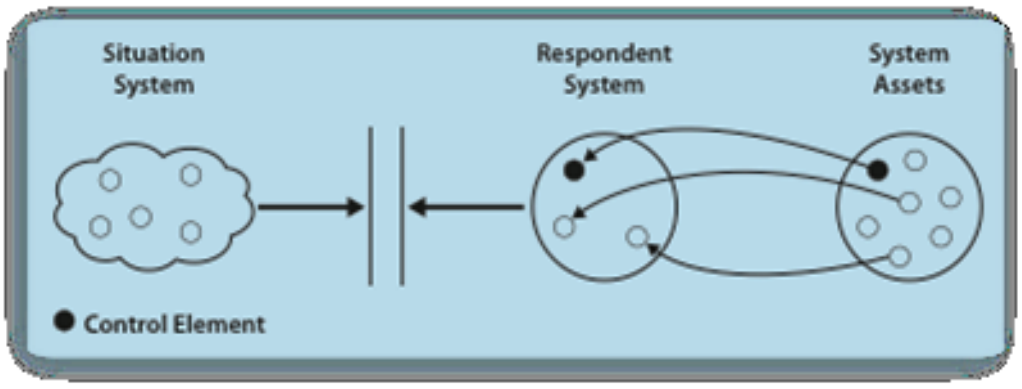

Figure 1: System Coupling Diagram

- Situation System – A problem or opportunity situation; either unplanned or planned. The situation may be the work of nature, be man-made, a combination of both or a postulated situation (Thematic System) that is to be used as a basis for deeper understanding and training (for example, business games or military exercises). Thus, the situation may be catastrophe, terrorist action, the capabilities needed for a new system, the next stage in a life cycle of a system. In all cases, in order to affect the situation a response is required.
- Respondent System – The system created to respond to the situation where the parallel bars indicate that this system interacts with the situation and transforms the situation to a new situation. A Respondent System, based upon the situation that is being treated can have several names such as Project, Program, Mission, Task Force, or

in a scientific context, Experiment. Note that one of the system elements of this system is a control element that directs the operation of the respondent system in its interaction with the situation. This element is based upon an instantiation of a Control System asset, for example a Command and Control System, or a control process of some form.

- System Assets – The sustained assets of an enterprise that are to be utilized in responding to situations. System assets must be adequately life cycle managed so that when instantiated in a Respondent System will perform their function. These are the systems that are the primary objects of an Enterprise and include their value added products or services as well as their infrastructure systems. Examples of assets include concrete systems such as produced products and/or services, facilities, instruments and tools as well as abstract systems such as theories, knowledge, processes and methods.

System Definition (glossary)

A set of core technical activities of systems engineering, including the activities that are completed primarily in the front-end portion of the system design. This consists of the definition of system requirements, the design of one or more logical and physical architectures, and analysis and selection between possible solution options. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

System definition is a knowledge area in the SEBoK that includes several front-end systems engineering activities, such as system requirements development; functional, logical and physical architectural design, and system analysis. This generally aligns with the "concept stage" as discussed in INCOSE (2012). In the SEBoK, system concept definition is used to discuss the assessment of the mission and stakeholder requirements.

Work Cited

INCOSE. 2012. *Systems Engineering Handbook: A Guide for System Life Cycle Processes and Activities*, version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2.

System Deployment and Use (glossary)

> *A set of core technical activities of systems engineering in ensure that the developed system is operationally acceptable and that the responsibility for the effective, efficient, and safe operations of the system is transferred to the owner. Considerations for deployment and use must be included throughout the system life cycle.* (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

System Deployment and Use is a SEBoK knowledge area; it includes systems engineering activities for system deployment and operation in its operational environment; and for the maintenance and logistics support of the system through life.

System Element (glossary)

> *A member of a set of elements that constitutes a system. A system element is a discrete part of a system that can be implemented to fulfill specified requirements. A system element can be hardware, software, data, humans, processes (e.g., processes for providing service to users), procedures (e.g., operator instructions), facilities, materials, and naturally occurring entities (e.g., water, organisms, minerals), or any combination.* (ISO/IEC 15288:2015)

- Contributing Authors:
- Michael Berry, Brian Cohen, Diganta Das, Houman Homayoun, and Thomas McDermott

-

This article describes the discipline of hardware assurance, especially as it relates to systems engineering. It is part of the SE and Quality Attributes Knowledge Area.

Overview

System hardware assurance is a set of system security engineering activities (see System Security for more information) undertaken to quantify and increase the confidence that electronics function as intended and only as intended throughout their life cycle, and to manage identified risks. The term *hardware* refers to electronic components, sometimes called integrated circuits or chips. As products of multi-stage processes involving design, manufacturing and post-manufacturing, packaging, and test, they must function properly under a wide range of circumstances. Hardware components – alone and integrated into subcomponents, subsystems, and systems – have weaknesses and vulnerabilities enabling exploitation. Weaknesses are flaws, bugs, or errors in design, architecture, code, or implementation. Vulnerabilities are weaknesses that are exploitable in the context of use (Martin 2014).

Hardware assurance is conducted to minimize risks related to hardware that can enable adversarial exploitation and subversion of functionality, counterfeit production, and loss of technological advantage. Challenges include increasing levels of sophistication and complexity of hardware architectures, integrated circuits, operating systems, and application software, combined with supply chain risks, emergence of new attack surfaces, and reliance on global sources for some components and technologies.

After identifying concerns and applicable mitigations, hardware assurance offers a range of possible activities and processes. At the component level, hardware assurance focuses on the hardware itself and the supply chain used to design and manufacture it; at the subcomponent, subsystems, and system levels, hardware assurance incorporates the software and firmware integrated with the component.

Engineering efforts to enhance trust in hardware have increased in response to complex hardware architectures, the increasing sophistication of adversarial attacks on hardware, and globalization of supply chains. These factors raise serious concerns about the security, confidentiality, integrity, and availability as well as the provenance and authenticity of hardware. The “root of trust” (NIST 2020) of a system is typically contained in the processes, steps, and layers of hardware components and across the systems engineering development cycle. System hardware assurance focuses on hardware components and their interconnections with software and firmware to reduce risks to proper function or other compromises of the hardware throughout the complete life cycle of components and systems. Advances in hardware assurance tools and techniques will strengthen designs, and enhance assurance during manufacturing, packaging, test, and deployment and operational use.

Life Cycle Concerns of Hardware Components

Hardware assurance should be applied at various stages of a component's life cycle from hardware architecture and design, through manufacturing and testing, and finally throughout its inclusion in a larger system. The need for hardware assurance then continues throughout its operational life including sustainment and disposal.

As semiconductor technology advances the complexity of electronic components, it increases the need to "bake-in" assurance. Risks created during architecture, design, and manufacturing are challenging to address during the operational phase. Risks associated with interconnections between and among chips are also a concern. Therefore, improving a hardware assurance posture must occur as early as possible in the life cycle, thereby reducing the cost and schedule impacts associated with "fixing" components later in the life cycle of the system.

A conceptual overview of the typical hardware life cycle (Figure 1) illustrates the phases of the life cycle of components, as well as the subsystems and systems in which they operate. In each phase multiple parties and processes contribute a large set of variables and corresponding attack surfaces. As a result, the potential exists for compromise of the hardware as well as the subcomponents and systems in which they operate; therefore, matching mitigations should be applied at the time the risks are identified.

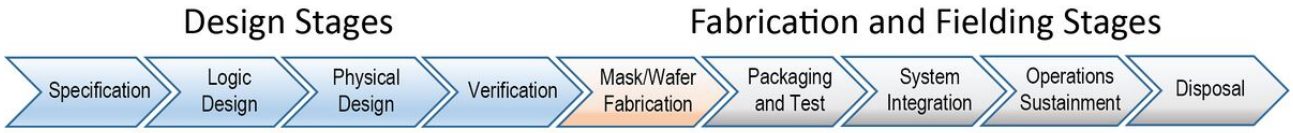

Figure 1. Component Life Cycle. (SEBoK Original)

Both the value of the hardware component and the associated cost of mitigating risks increase at each stage of the life cycle. Therefore, it is important to identify and mitigate vulnerabilities as early as possible. It takes longer to find and fix defects later, thereby increasing the complexity of replacing hardware with "corrected" designs that create system integration issues. In addition to cost savings, early correction and mitigation avoid delays in creating an operational system. It is essential to re-assess risks associated with hardware components throughout the life cycle periodically, especially as operational conditions change.

Hardware assurance during system sustainment is a novel challenge given legacy hardware and designs with their associated supply chains. In long-lived high-reliability systems, hardware assurance issues are compounded by obsolescence and diminished sourcing of components, thereby increasing concerns related to counterfeits and acquisitions from the gray market.

Function as Intended and Only as Intended

Exhaustive testing can check system functions against specifications and expectations; however, checking for unintended functions is problematic. Consumers have a reasonable expectation that a purchased product will perform as advertised and function properly (safely and securely, under specified conditions) – but consumers rarely consider if additional functions are built into the product. For example, a laptop with a web-conferencing capability comes with a webcam that will function properly when enabled, but what if the webcam also functions when turned off, thereby violating expectations of privacy? Given that a state-of-the-art semiconductor component might have billions of transistors, "hidden" functions might be exploitable by adversaries. The statement "function as intended and only intended" communicates the need to check for unintended functions.

Hardware specifications and information in the design phase are needed to validate that components function properly to support systems or missions. If an engineer creates specifications that support assurance that flow down the system development process, the concept of "function as intended" can be validated for the system and mission through accepted verification and validation processes. "Function only as intended" is also a consequence of capturing the requirements and specifications to assure the product is designed and developed without extra

functionality. For example, a Field Programmable Gate Array (FPGA) contains programmable logic that is highly configurable; however, the programmable circuitry might be susceptible to exploitation.

Given the specifications of a hardware component, specialized tools and processes can be used to determine with a high degree of confidence whether the component's performance meets specifications. Research efforts are underway to develop robust methods to validate that a component does not have capabilities that threaten assurance or that are not specified in the original design. Although tools and processes can test for known weaknesses, operational vulnerabilities, and deviations from expected performance, all states of possible anomalous behavior cannot currently be determined or predicted.

Data and information can be used to validate the component's function and should be collected from multiple sources including designers, developers, and members of the user community. Designers and developers can provide deep understanding of the component's intended function and provide tests used to verify its functional performance before fielding. The merging of component design and development information with extensive field data, including third-party evaluation, contributes to assurance that the component is performing specified functions and that no unintended functionality is observed.

Risks to Hardware

Modern systems depend on complex microelectronics, but advances in hardware without attention to associated risks can expose critical systems, their information, and the people who rely on them. "Hardware is evolving rapidly, thus creating fundamentally new attack surfaces, many of which will never be entirely secured". (Oberg 2020) Therefore, it is imperative that risk be modeled through a dynamic risk profile and be mitigated in depth across the entire profile. Hardware assurance requires extensible mitigations and strategies that can and do evolve as threats do. Hardware assurance methods seek to quantify and improve confidence that weaknesses that can become vulnerabilities that create risks are mitigated.

Most hardware components are commercially designed, manufactured, and inserted into larger assemblies by multi-national companies with global supply chains. Understanding the provenance and participants in complex global supply chains is fundamental to assessing risks associated with the components.

Operational risks that derive from unintentional or intentional features are differentiated based on the source of the feature. Three basic operational risk areas related to goods, products, or items are: failure to meet quality standards, maliciously tainted goods, and counterfeit hardware. Counterfeits are usually offered as legitimate products, but they are not. They may be refurbished or mock items made to appear as originals, re-marked products, the result of overproduction, or substandard production parts rejected by the legitimate producer. Counterfeit risks and substandard quality offer avenues for malware insertion and potential impacts to overall system performance and availability.

Failure to follow quality standards including safety and security standards, especially in design, can result in unintentional features or flaws being inadvertently introduced. These can occur through mistakes, omissions, or lack of understanding how features might be manipulated by future users for nefarious purposes. Features introduced intentionally for specific purposes can also make the hardware susceptible to espionage or control of the hardware at some point in its life cycle.

Quantify and Improve Confidence

The quantification of hardware assurance is a key technical challenge because of the complex interplay among designer, manufacturer and supply chains, and adversarial intent, as well as the challenge of defining "security" with respect to hardware function. Quantification is necessary to identify and manage hardware risks within program budgets and timeframes. It enables a determination of the required level of hardware assurance and whether quantification is achievable throughout the hardware's life cycle.

Current methods for quantifying hardware assurance are adapted from the fields of quality and reliability engineering, which use methods like Failure Mode and Effects Analysis (FMEA). (SAE 2021) FMEA is semi-quantitative and combines probabilistic hardware failure data and input from experts. Adapting FMEA to quantify hardware assurance is hampered when it relies on assigning probabilities to human behavior that may be motivated by money, malicious intent, etc. Expert opinion often varies when quantifying and weighting factors used in generating risk matrices and scores. In response, recent efforts are attempting to develop quantitative methods that reduce subjectivity.

Game theoretic analysis (game theory) is the creation of mathematical models of conflict and cooperation between intelligent and rational decision-makers. (Myerson 1991) Models include dynamic, as opposed to static, interactions between attackers and defenders that can quantify the risks associated with potential interactions among adversaries, hardware developers, and manufacturing processes. (Eames and Johnson 2017) Creation of the models forces one to define attack scenarios explicitly and to input detailed knowledge of hardware development and manufacturing processes. Outputs of the model may include a ranking of the most likely attacks to occur based on cost-benefit constraints on the attackers and defenders. (Graf 2017) The results can empower decision-makers to make quantitative trade-off decisions about hardware assurance.

Another quantification method that results in a confidence interval for detecting counterfeit/suspect microelectronics is presented in the SAE AS6171 standard. (SAE 2016) Confidence is based on knowing the types of defects associated with counterfeits, and the effectiveness of different tests to detect those defects. Along the same lines, a standard for hardware assurance might be developed to quantify the confidence interval by testing against a catalogue of known vulnerabilities, such as those documented in the MITRE Common Vulnerabilities and Exposures (CVE) list. (MITRE 2020)

Distributed ledger technology (DLT) is an example of an emerging technology that could enable a standardized approach for quantifying hardware assurance attributes such as data integrity, immutability, and traceability. DLT can be used in conjunction with manufacturing data (such as dimensional measurement, parametric testing, process monitoring, and defect mapping) to improve tamper resistance using component provenance and traceability data. DLT also enables new scenarios of cross-organizational data fusion, opening the door to new classes of hardware integrity checks.

Manage Risks

The selection of specific components for use in subsystems and systems should be the outcome of performance-risk and cost-benefit trade-off assessments in their intended context of use. The goal of risk management and mitigation planning is to select mitigations with the best overall operational risk reduction and the lowest cost impact. The required level of hardware assurance varies with the criticality of a component's use and the system in which it is used.

During a typical development life cycle of a system – architecture, design, code, and implementation – various types of problems can pose risks to the operational functionality of the hardware components provided. These risks include weaknesses or defects that are inadvertent (unintentional), as well as counterfeits that may be either inadvertent or intentionally injected into the supply chain for financial motivations or malicious components designed to change functionality.

Managing risk in the context of hardware assurance seeks to decrease the risk of weaknesses that create attack surfaces that can be exploited, while improving confidence that an implementation resists exploitation. Ideally, risk management reduces risk and maximizes assurance to an acceptable level. Often, risks are considered in the context of likelihood of consequences and the costs and effectiveness of mitigations. However, new operationally impactful risks are recognized continuously over the hardware life cycle and supply chains of components. At the same time hardware weaknesses are often exploited through software or firmware. Therefore, to maximize assurance and minimize operationally impactful risks mitigation-in-depth across all constituent components must be considered.

This highlights the need for a dynamic risk profile.

An example of a post-manufacturing mitigation involves a new hardware risk identified during field operation. A dynamic risk profile can be used to characterize the issue and identify possible resources to address the suspect component function. This profile can also be used to track and address risks throughout its life, including obsolescence-related risk. One means of mitigating this kind of hardware life cycle risk is the use of existing programmable logic.

Just as with software patches and updates, new attack surfaces on hardware may become exposed through the mitigation being applied, and they will likely take a long time to discover. In the example above, the programmable logic is updated to provide a new configuration to protect the hardware. In this context, access to hardware reconfiguration must be limited to authorized parties to prevent an unauthorized update that introduces weaknesses on purpose or by accident. While programmable logic may have mitigated a specific attack surface or type of weakness, additional mitigations are needed to minimize risk more completely. This is mitigation-in-depth – multiple mitigations building upon one another.

Throughout the entire supply chain, critical pieces of information can be inadvertently exposed. The exposure of such information directly enables the creation and exploitation of new attack surfaces. Therefore, the supply chain infrastructure must also be assessed for weaknesses, and the development, use, and maintenance of hardware components assured. The dynamic risk profile offers a framework to balance mitigations in the context of risk and cost throughout the complete hardware and system life cycles.

System of Systems (SoS) (glossary)

(1) Two or more systems that are separately defined but operate together to perform a common goal. (Checkland 1999)

(2) an assemblage of components which individually may be regarded as systems, and which possess two additional properties: (a) Operational Independence of the Components: If the system-of-systems is disassembled into its component systems the component systems must be able to usefully operate independently. That is, the components fulfill customer-operator purposes on their own.

(b) Managerial Independence of the Components: The component systems not only can operate independently, they do operate independently. The component systems are separately acquired and integrated but maintain a continuing operational existence independent of the system-of-systems. (Maier 1998, 267-284)

(3) System-of-systems applies to a system-of-interest whose system elements are themselves systems; typically these entail large scale inter-disciplinary problems with multiple, heterogeneous, distributed systems. (INCOSE 2012)

System Realization (glossary)

The activities required to build a system, integrate disparate system elements, and ensure that a system both meets the needs of stakeholders and aligns with the requirements identified in the system definition stage. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

"System realization" is used in the SEBoK as a knowledge area (KA); it includes several systems engineering (SE) activities such as system implementation, integration, verification, and validation. (See System Realization KA.) This generally aligns with the "development" and "production" stages as discussed in the International Council on Systems Engineering (INCOSE) Systems Engineering Handbook (INCOSE 2012).

Work Cited

INCOSE. 2012. Systems Engineering Handbook: A Guide for System Life Cycle Processes and Activities, version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2.

System Requirement (glossary)

(1a) A statement that transforms the stakeholder, user-oriented view of desired capabilities into a technical view, of a solution that meets the operational needs of the user. (ISO/IEC/IEEE, 2015, section 6.4.2)

(1b) The System Requirement Definition process creates a set of measurable system requirements that specify, from the supplier's perspective, what characteristics, attributes, and functional and performance requirements the system is to possess, in order to satisfy stakeholder requirements. (ISO/IEC/IEEE, 2015, section 6.4.2)

Source

(1) ISO/IEC/IEEE. 2015. *Systems and Software Engineering - System Life Cycle Processes*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 15288:2015 (E).

Discussion

Both definitions are modified from the introduction to the Requirements Analysis process, there is no formal definition of the term "system requirement" in the standard.

The term (engineered system) has been substituted for the word (product) in definition 1a to better align with the terminology used in the SEBoK.

For a full discussion of the role and importance of system requirements in systems engineering see the System Requirements article.

System-of-Interest (glossary)

(1) The system whose life cycle is under consideration. (ISO/IEC/IEEE 2015)

(2) The system of interest to an observer. (Bertalanffy 1968)

Source

(1) ISO/IEC/IEEE. 2015. *Systems and Software Engineering - System Life Cycle Processes*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC), Institute of Electrical and Electronics Engineers. ISO/IEC/IEEE 15288:2015. The second definition is an expanded version of the ISO/IEC/IEEE version.

(2) von Bertalanffy, L. 1968. *General system theory: Foundations, development, applications,* revised ed. New York, NY: Braziller.

Discussion

(1) Is the common Systems Engineering definition. A system-of-interest is a collective set of all elements of any system considered by a lifecycle, this may include both operational or enabling systems. Strictly this definition is relevant for an Engineered System (glossary) of interest.

(2) Is the system science definition and applies to all systems irrespective of whether they have a purpose or lifecycle in an engineering sense.

Systemist (glossary)

A systemist (from Greek chēm(ía) alchemy; replacing chymist from Medieval Latin alchimista) is a scientist trained in the study of System Science.

Discussion

“We use this term for people who have the capabilities to understand complex situations, to cope with the unusual, to identify the right problem in order to solve it and who are able to take decisions keeping in mind a vision for the future” (Brigitte Daniel-Allegro and Gary Smith 2016). “The chemist uses their understanding of chemical elements when they interact with chemical substances. Likewise, in the future the systemist will use their understanding of systemics when they manipulate and transform systems” (Gary Smith 2020)

Systems Approach (glossary)

A set of principles for applying systems thinking to engineered system contexts. (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

This definition has been created from a number of relevant sources on Systems Thinking, see the Systems Approach Applied to Engineered Systems knowledge area.

Systems Biology (glossary)

Systems biology is the computational and mathematical modeling of complex biological systems.

Source

https://en.wikipedia.org/wiki/Systems_biology

Discussion

An emerging engineering approach applied to biological scientific research, systems biology is a biology-based inter-disciplinary field of study that focuses on complex interactions within biological systems, using a holistic approach (holism instead of the more traditional reductionism) to biological research. Particularly from year 2000 onwards, the concept has been used widely in the biosciences in a variety of contexts. For example, the Human Genome Project is an example of applied systems thinking in biology which has led to new, collaborative ways of working on problems in the biological field of genetics.One of the outreaching aims of systems biology is to model and discover emergent properties, properties of cells, tissues and organisms functioning as a system whose theoretical description is only possible using techniques which fall under the remit of systems biology. These typically involve metabolic networks or cell signaling networks. (Wikipedia, "Systems Biology")

Systems Concept (glossary)

A mode of description, which explains an aspect of an object in terms of a set of interacting elements. The object can, in principle, be anything: a physical object, a body of work, an idea, or an enterprise. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

For a full discussion of the role and importance of systems concepts in systems engineering see the System Concept Definition article.

Systems Development (glossary)

> *A process that usually includes requirements analysis, system design, implementation, documentation and quality assurance.* (ISO/IEC 1990)

Sources

ISO/IEC. 1990. *Information technology--Vocabulary--Part 20: System development*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC 2382-20:1990.

Discussion

None.

Systems Engineer (glossary)

A systems engineer is "a person who practices systems engineering" and whose systems engineering capabilities and experience include sustained practice, specialization, leadership or authority over systems engineering activities. Systems engineering activities may be conducted by any competent person regardless of job title or professional affiliation. (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

Systems engineer is not a term in ISO/IEC/IEEE 24865:2010. The INCOSE website has a description but not a definition:

> *Systems engineers concentrate their efforts on the aspects of the engineering process (requirements definition, top-level functional designs, project management, life cycle cost analysis,...) that serve to organize and coordinate other engineering activities. The systems engineer is the primary interface between management, customers, suppliers, and specialty engineers in the systems development process.*

Systems Engineering (glossary)

The definition of systems engineering has evolved over time. The current accepted definitions are found below:

> (1) *Interdisciplinary approach governing the total technical and managerial effort required to transform a set of customer needs, expectations, and constraints into a solution and to support that solution throughout its life.* (ISO/IEC/IEEE 2010)
>
> (2) *An interdisciplinary approach and means to enable the realization of successful systems. It focuses on defining customer needs and required functionality early in the development cycle, documenting requirements, then proceeding with design synthesis and system validation while considering the complete problem:*

- *Operations*
- *Performance*
- *Test*
- *Manufacturing*
- *Cost & Schedule*
- *Training & Support*
- *Disposal*

> *Systems engineering integrates all the disciplines and specialty groups into a team effort forming a structured development process that proceeds from concept to production to operation. Systems engineering considers both the business and the technical needs of all customers with the goal of providing a quality product that meets the user needs.* (INCOSE 2012)
>
> (3) *A transdisiplinary and integrative approach to enable the successful realization, use, and retirement of engineered systems, using systems principles and concepts, and scientific, technological, and management methods.*
>
> We use the terms “engineering” and “engineered” in their widest sense: “the action of working artfully to bring something about”. “Engineered systems” may be composed of any or all of people, products, services, information, processes, and natural elements. (INCOSE Fellows 2019)

Source

(1) ISO/IEC/IEEE. 2010. *Systems and Software Engineering - System and Software Engineering Vocabulary (SEVocab)*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/ Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 24765:2010.

(2) INCOSE. 2012. *INCOSE Systems Engineering Handbook*, version 3.2.2. San Diego, CA, USA: International Council on Systems Engineering (INCOSE), INCOSE-TP-2003-002-03.2.2.

(3) INCOSE Fellows, Briefing to INCOSE Board of Directors, January 2019.

Discussion

There are many definitions of systems engineering. The SEBOK presents three of those definitions. Two come from foundational documents.

Note that both stress the interdisciplinary nature of systems engineering and its application throughout the life of the system.

In the Systems Engineering Overview article, the authors modified the INCOSE definition, saying traditional definitions of SE have emphasized sequential performance of SE activities, e.g., “documenting requirements, then proceeding with design synthesis …”. (INCOSE 2012) The SEBoK authors depart from tradition to emphasize the inevitable intertwining of system requirements definition and system design in the following revised definition of SE:

> *Systems Engineering (SE) is an interdisciplinary approach and means to enable the realization of successful systems. It focuses on holistically and concurrently understanding stakeholder needs; exploring opportunities; documenting requirements; and synthesizing, verifying, validating, and evolving solutions while considering the complete problem, from system concept exploration through system disposal.*

Definition (3) was created by the INCOSE Fellows Initiative on System and Systems Engineering Definitions. This was established in 2016, to review current INCOSE definitions of SYSTEM and SYSTEMS ENGINEERING and to recommend any changes necessary to align the definitions to a) current practice, and b) the aspirations of INCOSE’s 2025 Vision. At the January 2019 INCOSE Board of Directors meeting, a new INCOSE definition for "system" was approved and is given above.

The Fellows Initiative on System and Systems Engineering Definitions was established in 2016, to review current INCOSE definitions of SYSTEM and SYSTEMS ENGINEERING and to recommend any changes necessary to align the definitions to a) current practice, and b) the aspirations of INCOSE’s 2025 Vision. The INCOSE Fellows elaborated this definition by stating: We use the terms “engineering” and “engineered” in their widest sense: “the action of working artfully to bring something about”. “Engineered systems” may be composed of any or all of people, products, services, information, processes, and natural elements.

Systems Engineering Management (SEM) (glossary)

Managing the resources and assets allocated to perform systems engineering activities. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

None.

Systems Engineering Plan (SEP) (glossary)

A systems engineering plan (SEP) is a "living" document that captures a program's current and evolving systems engineering strategy and its relationship with the overall program management effort. The SEP purpose is to guide all technical aspects of the program. It should be established early in the Materiel Solution Analysis phase and updated continually. (DAU 2012)

Source

DAU 2012. "Systems Engineering Plan (SEP)." (online). Virginia, USA: ACQuipedia. Your Online Acquisition Encyclopedia. Accessed on 20 October 2019. Available at: https://www.dau.edu/acquipedia/pages/articledetails.aspx#!206.

Discussion

In many contexts, the Systems Engineering Plan (SEP) and Systems Engineering Management Plan (SEMP) are used interchangeably, to refer to the highest level technical plan. However, in the context of the U.S. Department of Defense the context, intent, and content of these documents are quite different:

- The SEP is a high-level plan that is made before the system acquisition and development begins. It is written by the government customer.
- The SEMP is the specific development plan written by the developer (or contractor).

Systems Integration (glossary)

A broad topic that includes hardware, software, and human systems and which uses an interdisciplinary approach for a structured, disciplined, and documented technical effort to simultaneously design and develop systems products and processes used to create cohesive systems. (Created for SEBoK)

Source

This definition was developed for the SEBoK.

Discussion

None.

Systems Science (glossary)

Systems science is an interdisciplinary field of science that studies the nature of complex systems in nature, society, and science. It aims to develop interdisciplinary foundations, which are applicable in a variety of areas, such as engineering, biology, medicine and social sciences. (Farlex 2012)

Source

Farlex 2012. "Systems Science." (online). Pennsylvania, USA: Farlex. The Free Dictionary. Access on 11 September 2012. Available at: http://encyclopedia.thefreedictionary.com/systems+science

Discussion

Please see the Systems Science knowledge area.

Systems Thinking (glossary)

(1) An epistemology which, when applied to human activity is based on four basic ideas: emergence, hierarchy, communication, and control as characteristics of systems. (Checkland 1999)

(2) A process of discovery and diagnosis – an inquiry into the governing processes underlying the problems and opportunities. (Senge 1990)

(3) A discipline for examining wholes, interrelationships, and patterns utilizing a specific set of tools and techniques. (Senge 1990)

Source

(1) Checkland, P. 1999. Systems Thinking, Systems Practice. New York, NY, USA: John Wiley & Sons.

(2) & (3) Senge, P.M. 1990. *The fifth discipline: The Art & Practice of the Learning Organization.* New York, NY, USA: Doubleday Business.

Discussion

Definition (1) is the System Science view, defining system thinking as a "theory of knowledge, esp. with regard to its methods, validity, and scope", based around seeing the world as systems.

Definitions (2) and (3) focus more on systems thinking as a collection of methods for dealing wih system problems. This aspect of systems thinking relates directly to the Systems Approach defined in the SEBoK.

See also the topic What is Systems Thinking?

T

Tailoring (glossary)

> Adapted from notes/discussion of "tailoring guide" (ISO/IEC/IEEE 2009): Tailoring a process adapts the process description for a particular end. For example, a project creates its defined process by tailoring the organization's set of standard processes to meet the objectives, constraints, and environment of the project. (ISO/IEC/IEEE 2009)

Sources

ISO/IEC/IEEE 24774:2021, Clause 3.20.

Discussion

None.

Team (glossary)

> *A group of people with a full set of complementary skills required to complete a task, job, or project. Team members (1) operate with a high degree of interdependence, (2) share authority and responsibility for self-management, (3) are accountable for the collective performance, and (4) work toward a common goal and shared reward(s). A team becomes more than just a collection of people when a strong sense of mutual commitment creates synergy, thus generating performance greater than the sum of the performances of its individual members.* (WebFinance 2012)

Sources

WebFinance. 2012. "dictionary.com" (online). Washington, DC, USA: WebFinance, Inc. Accessed on 11 September 2012. Available at: http://www.businessdictionary.com/definition/team.html.

Discussion

This definition encompasses the key elements of "team." Other characteristics of systems engineering teams are a sense of shared commitment to achieving the end result, shared work products, and willingness to help one another. As pointed out in the definition, a team is more than a collection, or group of people. A systems engineering team is a group of individuals who cooperatively perform a collection of systems engineering tasks based on a shared vision and a common set of engineering objectives.

Technical Management (glossary)

> *The purpose of Technical Management is to steer the technical effort (commencing when the opportunity is identified) along the correct technical path to solution. Technical Management ensures integration (provides a bridge) between business / project management and all technical activity. Technical Management determines how the system approach can be carried out most effectively and efficiently in the attainment of value, cost targets and achievement of time-to-market.* (INCOSE 2020)

Source

INCOSE. 2020. "PM-SE Integration Working Group." https:/ / www. incose. org/ incose-member-resources/ working-groups/process/pm-se-integration [1]

Discussion

This is a primary topic of interest for the INCOSE PM/SE Integration Working Group.

Discussion

None.

Temporal Architecture (glossary)

> *A temporal classification of the functions of a system according to the frequency level of execution. Temporal architecture includes the definition of synchronous and asynchronous aspects of functions.* (Created for SEBoK)

Sources

This definition was developed for SEBoK.

Discussion

The definition provided here is consistent with a multiple view of a system logical architecture that should include as a minimum functional, behavioral and temporal views.

Test Cases (glossary)

> *A set of test inputs, execution conditions, and expected results developed for a particular objective, such as to exercise a particular program path or to verify compliance with a specific requirement.* (IEEE 2004)

Sources

IEEE. 2004. *IEEE Standard for Software Verification and Validation*. Washington, DC, USA: Institute of Electrical and Electronics Engineers (IEEE). IEEE 1012-2004.

Discussion

None.

Threat (glossary)

> *State of the system or system environment which can lead to adverse effects.* (ISO/IEC/IEEE 2011)

Sources

Total Ownership Cost (glossary)

> *The sum of all financial resources necessary to organize, sustain, and operate military forces sufficient to meet national goals in compliance with all laws, all policies applicable to DoD, all standards in effect for readiness, safety, and quality of life, and other official measures of performance in effect for DoD and its Components.)* (Miller 2007)

Sources

Miller, K. 2007. DoD Defintion of Total Ownership Cost (TOC). Los Angeles: University of Southern California.

Discussion

The term "total ownership cost" is a term used primarily but not exclusively by the US Department of Defense (DoD). The quote was extracted from a presentation by Dr. Karen Miller a lecturer at the University of Southern California and Loyola Marymount University, both in Los Angeles. Dr. Miller is an authority on system affordability which includes the concept of total ownership cost.

Traceability (glossary)

> The degree to which a relationship can be established between two or more products of the development process, especially products having a predecessor-successor or master-subordinate relationship to one another (IEEE 1233-1998 (R2002) IEEE Guide for Developing System Requirements Specifications, 3.1.9)

V

Validation (glossary)

(1a) *Confirmation, through the provision of objective evidence, that the (stakeholder) requirements for a specific intended use or application have been fulfilled.* (ISO 9000:2015)

(1b) *The set of activities ensuring and gaining confidence that a system is able to accomplish its intended use, goals and objectives (i.e., meet stakeholder requirements) in the intended operational environment. The right system was built.* (ISO/IEEE 2015, 1, Section 6.4.8)

(2) *The assurance that a product, service, or system meets the needs of the customer and other identified stakeholders. It often involves acceptance and suitability with external customers. Contrast with verification.* (PMI 2013)

(3) *The process of providing evidence that the software and its associated products satisfy system requirements allocated to software at the end of each life cycle activity, solve the right problem, and satisfy intended use and user needs.* (IEEE 1012-2004, 3.1.35)

Source

(1) ISO/IEC/IEEE. 2015. *Systems and Software Engineering - System Life Cycle Processes*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 15288:2015 (E).

(2) PMI. 2013. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*. 5th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

(3) IEEE. 2004. *IEEE Standard for Software Verification and Validation.* Institute of Electrical and Electronics Engineers (IEEE) Standards Association: 3.1.35. IEEE 1012-2004.

Discussion

Definition (1a) refers to the outcome of providing evidence that a particular system realization is validated (i.e., Does it satisfy the customer and user needs as stated and agreed?). The word (stakeholder) has been added to clarify the definition.

Definition (1b) is based on the introduction to the validation process and refers to the process of achieving validation through a set of activities conducted across a system's Life Cycle (glossary) to ensure that the system that has been built will serve its intended purpose. The term (engineered) system has been added to conform to SEBoK terminology.

Definition (3) refers to the validation of software components in terms of satisfying both allocated system requirements as well as user needs.

Validation builds on the activities and outcome of verification, a process that confirms that the system has been built correctly (i.e., Does it satisfy the system requirements?).

For a full discussion of the role and importance of validation in systems engineering see the System Validation article.

Value (glossary)

(1) *Value: the regard, merit, importance or worth given to something. It is the basis for showing a preference i.e. making a choice.* (Penguin Dictionary of Civil Engineering)

(2) *Numerical or categorical result assigned to a base measure, derived measure or indicator.* (PSM 2010; ISO/IEC/IEEE 2007)

(3) *A measure of worth (e.g., benefit divided by cost) of a specific product or service by a customer, and potentially other stakeholders;* (McManus 2005)

Note: "Values" are shared beliefs about what an organization or its members consider to be important. (1) A personal and/or cultural value is an absolute or relative ethical value, the assumption of which can be the basis for ethical action. A value system is a set of consistent values and measures. (Wikipedia) (2) Values are the principles or standards of behavior. The things to which we give value and which determine how we behave. Some important personal values are truth, honesty, trust, respect for others and for the environment, fairness, making what we do enjoyable for others with whom we interact, openness, competence, sustainability, balance, harmony, reasonableness. Wherever possible key performance indicators (KPIs) should reflect the relevant values within a process of all stakeholders. In this way you have a better chance of driving out waste and adding value to all of those involved. See ethics, worth. – see ethics, morals, codes of conduct. (Penguin Dictionary of Civil Engineering)

Source

(1) Penguin Dictionary of Civil Engineering

(2) PSM. 2010. *Practical Software and Systems Measurement: A Foundation for Objective Project Management*. version 4.0 ed. Bethesda, MD, USA: Practical Software and Systems Measurement (PSM).

ISO/IEC/IEEE. 2007. *Measurement Process*. Geneva, Switzerland: International Organization for Standards (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical & Electronics Engineers (IEEE), ISO/IEC/IEEE 15939.

(3) McManus, H. L. 2005. *Product Development Value Stream Mapping Manual*, release 1.0. Boston, MA, USA: Lean Aerospace Initiative (LAI)/Massachusetts Institute of Technology (MIT), PVDSM Manual 1.0.

Discussion

In systems engineering we generally use the notion of "value" to describe the amount of benefit some thing, feature or capability provides to various stakeholders. The term "worth" is often used in the same way, as a measure of benefit or "how much someone would pay for" something. From this viewpoint the McManus definition would be considered to be "value for money" rather than "value" per se.

In the SEBoK the need to clearly separate the notions of value and cost is stressed upon because the systems engineer needs to be clear on the distinction between value (or benefit), which is an attribute of the problem space and considers the optimum set of requirements to deliver customer satisfaction, and cost, which is an attribute of the solution, and may be different for different solutions to the same set of requirements. The concept of *value stream analysis* can be used to understand and optimize added value and associated costs through the value stream.

Systems Engineers also use "value" in the PSM sense of "the value of a given attribute".

Variety (glossary)

(1) A measure of the connectivity betwen system elements (Ashby 1956)

(2) Interacting systems stability increases with variety, and with the degree of connectivity of that variety within the environment (Hitchins 2007)

Sources

(1) Ashby, W.R. 1956. *Introduction to Cybernetics.* London, UK; J. Wiley.

(2) Hitchins, D. 2007. *Systems Engineering: A 21st Century Systems Methodology*. Hoboken, NJ, USA: Wiley .

Discussion

(1) Is a cybernetic term used to define the number of available connections between elements, and thus the potential routes for control actions.

(2) Is a systems engineering definition, in which variety of connections between elements is used as a way to increase the stability and potential of a system to achieve is goals. Hitchins refers to this as Connected Variety, and also discussed the limits on this conectivity applied by availability of time, space, resource.

Vee (V) Model (glossary)

The technical aspect of the project cycle is envisioned as a "Vee", starting with User needs on the upper left and ending with a User-validated system on the upper right. (Forsberg and Mooz 1991)

Source

Mooz, H. and K. Forsberg. 1991. Discussion

None.

Verification (glossary)

(1a) *Confirmation, through the provision of objective evidence, that specified (system) requirements have been fulfilled.* (ISO/IEC 2008, section 4.38)

(1b) *Verification is a set of activities that compares a system or system element against the required characteristics. This includes, but is not limited to, specified requirements, design description and the system itself. The system was built right.* (ISO/IEC/IEEE 2015, 1, Section 6.4.6)

(2) *The evaluation of whether or not a product, service, or system complies with a regulation, requirement, specification, or imposed condition. It is often an internal process. Contrast with validation.* (PMI 2013)

(3a) *The process of evaluating a system or component to determine whether the products of a given development phase satisfy the conditions imposed at the start of that phase.* (IEEE 1012-2004, 3.1.36)

(3b) *Process of providing objective evidence that the software and its associated products comply with requirements for all life cycle activities during each life cycle process, satisfy standards, practices, and conventions during life cycle processes, and successfully complete each life cycle activity and satisfy all the criteria for initiating succeeding life cycle activities.* (IEEE 829-2008, 3.1.54)

Source

(1) ISO/IEC/IEEE. 2015. *Systems and Software Engineering - System Life Cycle Processes*. Geneva, Switzerland: International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE). ISO/IEC/IEEE 15288:2015 (E).

(2) PMI. 2013. *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*. 5th ed. Newtown Square, PA, USA: Project Management Institute (PMI).

(3) IEEE. 2004. *IEEE Standard for Software Verification and Validation.* Institute of Electrical and Electronics Engineers (IEEE) Standards Association: IEEE 1012-2004.

Discussion

Definition (1a) refers to the outcome of providing evidence that a particular system realization is verified(i.e. Does it satisfy the specified and agreed system requirements?). The word (system) has been added to clarify the definition.

Definition (1b) is based on the introduction to the verification process and refers to the process of achieving verification through a set of activities conducted across a system's Life Cycle (glossary) to ensure the system has been built correctly. The term (engineered) system has been added to conform to SEBoK terminology.

Definition (3) refers to verification at the end of each lifecycle stage that confirms that both software and systems have been developed in compliance with all standard practices and rules.

Verification supports the activities and outcome of validation, a process that ensures that the correct system has been built for its intended use (i.e., Does it satisfy the customer and user needs?).

For a full discussion of the role and importance of verification in systems engineering see the System Verification article.

Verification and Validation Action (glossary)

A verification and validation action describes what must be verified or validated (the element as reference), on which element, the expected result, the validation/verification technique to apply, on which level of decomposition. (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

None.

Verification and Validation Configuration (glossary)

A grouping of all physical elements (system elements, Aggregates, Verification and Validation Tools) necessary to perform a Verification and Validation Procedure. (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

None.

Verification and Validation Procedure (glossary)

A verification and validation procedure groups a set of Verification and Validation Actions performed together (as a scenario of tests) in a given Verification and Validation Configuration. (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

None.

Verification and Validation Tool (glossary)

A verification and validation tool is a device or physical tool used to perform verification and validation procedures (test bench, simulator, cap/stub, launcher, etc.). (Created for SEBoK)

Sources

This definition was developed for the SEBoK.

Discussion

None.

Viable (glossary)

(1) Capable of working successfully; feasible. (Oxford English Dictionary)

(3) capable of living; especially : having attained such form and development as to be normally capable of surviving outside the mother's womb. (Oxford English Dictionary)

(3) A viable system is any system organised in such a way as to meet the demands of surviving in the changing environment. (Beer 1967)

Sources

(1) & (2) Oxford English Dictionary, 2013., s.v. "viable."

(3) Beer, S. 1967. *Cybernetics and Management,* 2nd edition. London, UK: English Universities Press.

Discussion

(1) and (2) are dictionary definitons which illustrate the two basic ideas of able to do its job, and have reached sufficent maturity to be able to survive in its environment.

(3) Is taken from Beer's Viable Systems Model, which describes the things an organization needs to be viable.

View (glossary)

A representation of a system from the perspective of a viewpoint. (OMG 2010)

Sources

OMG. 2010. *OMG Systems Modeling Language (OMG SysML™), Version 1.3*. Needham, MA, USA: Object Management Group. Accessed on 11 September 2012. Available at http://www.omg.org/technology/documents/domain_spec_catalog.htm#OMGSysML - derived from IEEE 1471.

Discussion

None.

Viewpoint (glossary)

> *A viewpoint is a specification of the conventions and rules for constructing and using a view for the purpose of addressing a set of stakeholder concerns* (OMG 2010)

Source(s)

OMG. 2010. OMG Systems Modeling Language (OMG SysML™), Version 1.3. Needham, MA, USA: Object Management Group. Available at http:/ / www. omg. org/ technology/ documents/ domain_spec_catalog. htm#OMGSysML - derived from IEEE 1471.

Discussion

None.

Vignette (glossary)

> *A small illustrative sketch. For the SEBoK, a vignette is a short implementation example written to become part of the SEBoK, where a case study introduction cites an existing, more extensive case study already available in the external literature.* (Adapted from Webster's Online Dictionary)

Sources

Webster's Online Dictionary. s.v. "Vignette."

Discussion

The base definition is from "Webster's Online Dictionary" at, http:/ / www. websters-online-dictionary. org/ definitions/vignette.The additional explanation was developed for SEBoK.. This definition describes the approach for vignettes in Systems Engineering Implementation Examples.

W

White-Box System (glossary)

A system where the inner components or logic are available for inspection. (Ashby 1956)

Sources

Ashby, W.R. 1956. *Introduction to Cybernetics*. London, UK: Wiley.

Discussion

None.

Wicked Problem (glossary)

Wicked problems are ill-defined, ambiguous and associated with strong moral, political and professional issues. Since they are strongly stakeholder dependent, there is often little consensus about what the problem is, let alone how to resolve it. (Ritchey 2011)

Sources

Ritchey, T. 2001. *Wicked Problems: Structuring Social Messes with Morphological Analysis.* Stockholm, Sweden: Swedish Morphological Society. Available online at: http://www.swemorph.com/pdf/wp.pdf.Accessed July 7, 2012.

Discussion

None.

Acronyms

Acronyms

The following is a list of acronyms and abbreviations which are used within the SEBoK.

SEBoK Acronyms. (Table Developed for BKCASE)

Acronym	Definition
	A
AADL	Architecture Analysis and Design Language
AAS	Advanced Automation System
ABD	Architecture Block Diagram
ACM	Association for Computing Machinery
ACS	Automated Case Support
ADM	Architecture Development Method
AECL	Atomic Energy of Canada
AF	Architecture Framework
AF CSE	Air Force Center for Systems Engineering (USA)
AFI	Air Force Instruction (USA)
AFIT	Air Force Institute of Technology (USA)
AFRI	Air Force Research Lab (USA)
AHP	Analytical Hierarchy Process
AIA	Aerospace Industries Association
AIAA	American Institute of Aeronautics and Astronautics (USA)

	(3)Initial Sector Suit System
IT	Information Technology
ITIL	Information Technology Infrastructure Library
ITS	Intelligent Transportation System
ITS-ETO	Intelligent Transport System-Emergency Transportation Operation
ITSM	Information Technology Services Management
ITU	International Telecommunications Union

K

KA	Knowledge Area
KPI	Key Performance Indicator
KPP	Key Performance Parameter
KSAA	Knowledge, Skills, Abilities, and Attitudes

L

LBS	Location Based Service
LCC	Life Cycle Cost
LCM	Life Cycle Management
LEfSE	Lean Enablers for Systems Engineering
LORA	Level of Repair Analysis
LRU	Line Replaceable Unit
LSE	(1) Lean Systems Engineering
	(2) Lead Systems Engineer
LSE WG	Lean Systems Engineering Working Group (INCOSE)

M

MA	Mission Analysis
MARTE	Modeling and Analysis for Real-Time and Embedded Systems
MBE	Model-Based Engineering
MBRA	Model-Based Risk Analysis
MBSE	Model-Based Systems Engineering
MCDA	Multi-Criteria Decision Analysis
MDA®	Model-Driven Architecture
ME	Mission Engineering
MIT	Massachusetts Institute of Technology
MOD	Ministry of Defence
MODAF	Ministry of Defence Architecture Framework (UK)
MOE	Measure of Effectiveness
MOP	Measure of Performance
MOS	Mean Opinion Score
MOSES	Model Oriented Systems Engineering
MPT	(1)Methods, Processes, and Tools
	(2)Methodologies, Processes, and Technologies
MRAR	Mishap Risk Assessment Report
MRL	Manufacturing Readiness Level
MRM	Manufacturing Resource Management
MS	Meta-System
MSA	Measurement System Analysis
MSL	Mean Sea Level

MSRB	Management Safety Review Board
MSTI	Miniature Seeker Technology Integration
MTBF	Mean Time Between Failures
MTTR	Mean Time to Repair
	N
NAHB	National Association of Home Builders
NAO	National Audit Office (UK)
NASA	National Aeronautics and Space Administration (USA)
NATO	North Atlantic Treaty Organization
NDI	Non-Developmental Item
NDIA	National Defense Industrial Association (NDIA)
NEPA	National Environmental Policy Act
NERC	North American Electric Reliability Corporation
NETMA	NATO Eurofighter and Tornado Management Agency
NIST	National Institute of Standards and Technology (USA)
NLP	Neuro-Linguistic Programming
NOAA	National Oceanographic and Atmospheric Agency
NPD	New Product Development
NPDP	New Product Development Process
NSA	National Security Agency
NSD	New service Development
NSOI	Narrower System-of-Interest
NSPE	National Society of Professional Engineers
NSTISSI	National Security Telecommunications Information Systems Security Issuance
NTIA	National Telecommunications and Information Administration (USA)
	O
O&S	Operations and Support
OAM&P	Operations, Administration, Management, and provisioning
OCR	Operations Commitment Review
OECD	Organization for Economic Co-Operative Development
OEM	Original Equipment Manufacturer
OGC	(1)Office of Government Commerce (UK)
	(2) Open Geospatial Consortium
OITL	Operator in the Loop
OMC	Operation/Maintenance/Closeout
